    Datum      *nodeLabels;     /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int         nNodes;         /* number of child nodes to be visited */
    int        *nodeNumbers;    /* their indexes in the node array */
    int        *levelAdds;      /* increment level by this much for each */
    Datum      *reconstructedValues;    /* associated reconstructed values */
    void      **traversalValues;        /* opclass-specific traverse values */
    double    **distances;              /* associated distances */
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys` = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes ordering operators (if any) in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is `(Datum) 0` at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `traversalMemoryContext` is the memory context in which to store output traverse values (see below). `level` is the current inner tuple's level, starting at zero for the root level. `returnData` is `true` if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked "all-the-same"; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 70.4.3). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. The reconstructed values are assumed to be of type `spgConfigOut.leafType`. (However, since the core system will do nothing with them except possibly copy them, it is sufficient for them to have the same `typlen` and `typbyval` properties as `leafType`.) If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array (nodes with lowest distances will be processed first).

Leave it NULL otherwise. If it is desired to pass down additional out-of-band information ("traverse values") to lower levels of the tree search, set `traversalValues` to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave `traversalValues` as NULL. Note that the `inner_consistent` function is responsible for palloc'ing the `nodeNumbers`, `levelAdds`, `distances`, `reconstructedValues`, and `traversalValues` arrays in the current memory context. However, any output traverse values pointed to by the `traversalValues` array should be allocated in `traversalMemoryContext`. Each traverse value must be a single palloc'd chunk.

`leaf_consistent`

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgLeafConsistentIn
{
    ScanKey     scankeys;       /* array of operators and comparison values */
    ScanKey     orderbys;       /* array of ordering operators and comparison
                                 * values */
    int         nkeys;          /* length of scankeys array */
    int         norderbys;      /* length of orderbys array */

    Datum       reconstructedValue;     /* value reconstructed at parent */
    void       *traversalValue; /* opclass-specific traverse value */
    int         level;          /* current level (counting from zero) */
    bool        returnData;     /* original data must be returned? */

    Datum       leafDatum;      /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum       leafValue;        /* reconstructed original data, if any */
    bool        recheck;          /* set true if operator must be rechecked */
    bool        recheckDistances; /* set true if distances must be rechecked */
    double     *distances;        /* associated distances */
} spgLeafConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys` = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes the ordering operators in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is `(Datum) 0` at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `level` is the current leaf tuple's level, starting at zero for the root level. `returnData` is `true` if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value of `spgConfigOut.leafType` stored in the current leaf tuple.

The function must return `true` if the leaf tuple matches the query, or `false` if not. In the `true` case, if `returnData` is `true` then `leafValue` must be set to the value (of type `spgConfigIn.attType`) originally

supplied to be indexed for this leaf tuple. Also, `recheck` may be set to `true` if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array. Leave it NULL otherwise. If at least one of returned distances is not exact, set `recheckDistances` to true. In this case, the executor will calculate the exact distances after fetching the tuple from the heap, and will reorder the tuples if needed.

The optional user-defined methods are:

`Datum compress(Datum in)`

Converts a data item into a format suitable for physical storage in a leaf tuple of the index. It accepts a value of type `spgConfigIn.attType` and returns a value of type `spgConfigOut.leafType`. The output value must not contain an out-of-line TOAST pointer.

Note: the `compress` method is only applied to values to be stored. The consistent methods receive query `scankeys` unchanged, without transformation using `compress`.

`options`

Defines a set of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since the representation of the key in SP-GiST is flexible, it may depend on user-specified parameters.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about pfree'ing everything you palloc. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

70.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

70.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to true only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple *must* divide the set of leaf values into more than one node group. If the operator class's `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 70.4.3.

When `longValuesOK` is true, it is expected that successive levels of the SP-GiST tree will absorb more and more information into the prefixes and node labels of the inner tuples, making the required leaf datum smaller and smaller, so that eventually it will fit on a page. To prevent bugs in operator classes from causing infinite insertion loops, the SP-GiST core will raise an error if the leaf datum does not become any smaller within ten cycles of `choose` method calls.

70.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return NULL for the `nodeLabels` array, and likewise the `choose` function can return NULL for the `prefixNodeLabels` array during a `spgSplitTuple` action. This will in turn result in `nodeLabels` being NULL during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases.

70.4.3. “All-the-Same” Inner Tuples

The SP-GiST core can override the results of the operator class's `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn't match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

Chapter 71. GIN Indexes

71.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their *website*.

71.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GIN operator classes shown in Table 71.1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

Table 71.1. Built-in GIN Operator Classes

Name	Indexable Operators
array_ops	&& (anyarray,anyarray)
	@> (anyarray,anyarray)
	<@ (anyarray,anyarray)
	= (anyarray,anyarray)
jsonb_ops	@> (jsonb,jsonb)
	@? (jsonb,jsonpath)
	@@ (jsonb,jsonpath)
	? (jsonb,text)
	?| (jsonb,text[])
	?& (jsonb,text[])
jsonb_path_ops	@> (jsonb,jsonb)
	@? (jsonb,jsonpath)
	@@ (jsonb,jsonpath)
tsvector_ops	@@ (tsvector,tsquery)

Name	Indexable Operators
	`@@@ (tsvector,tsquery)`

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

71.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

`Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)`

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the item contains no keys.

`Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)`

Returns a palloc'd array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see Section 41.16.2). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the `query` contains no keys.

`searchMode` is an output argument that allows `extractQuery` to specify details about how the search will be done. If `*searchMode` is set to `GIN_SEARCH_MODE_DEFAULT` (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If `*searchMode` is set to `GIN_SEARCH_MODE_INCLUDE_EMPTY`, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If `*searchMode` is set to `GIN_SEARCH_MODE_ALL`, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

`pmatch` is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of `*nkeys bool`s and store its address at `*pmatch`. Each element of the array should be set to true if the corresponding key requires partial match, false if not. If `*pmatch` is set to `NULL` then GIN assumes partial match is not required. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not support partial match.

`extra_data` is an output argument that allows `extractQuery` to pass additional data to the `consistent` and `comparePartial` methods. To use it, `extractQuery` must allocate an array of `*nkeys` pointers and store its address at `*extra_data`, then store whatever it wants to into the individual pointers.

The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a Boolean consistent function, and a ternary triConsistent function. triConsistent covers the functionality of both, so providing triConsistent alone is sufficient. However, if the Boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the Boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns true if an indexed item satisfies the query operator with strategy number n (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The check array has length nkeys, which is the same as the number of keys previously returned by extractQuery for this query datum. Each element of the check array is true if the indexed item contains the corresponding query key, i.e., if (check[i] == true) the i-th key of the extractQuery result array is present in the indexed item. The original query datum is passed in case the consistent method needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element is true if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT DISTINCT FROM. The consistent function can examine the corresponding nullFlags[] element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to true if the heap tuple needs to be rechecked against the query operator, or false if the index test is exact. That is, a false return value guarantees that the heap tuple does not match the query; a true return value with *recheck set to false guarantees that the heap tuple does match the query; and a true return value with *recheck set to true means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

triConsistent is similar to consistent, but instead of Booleans in the check vector, there are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE and GIN_TRUE have the same meaning as regular Boolean values, while GIN_MAYBE means that the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item certainly does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, a GIN_MAYBE return value is the equivalent of setting the recheck flag in the Boolean consistent function.

In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default btree operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the btree operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

An operator class for GIN can optionally supply the following methods:

`int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)`

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

`void options(local_relopts *relopts)`

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in GIN are flexible, they may depend on user-specified parameters.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See Section 71.4.2 for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

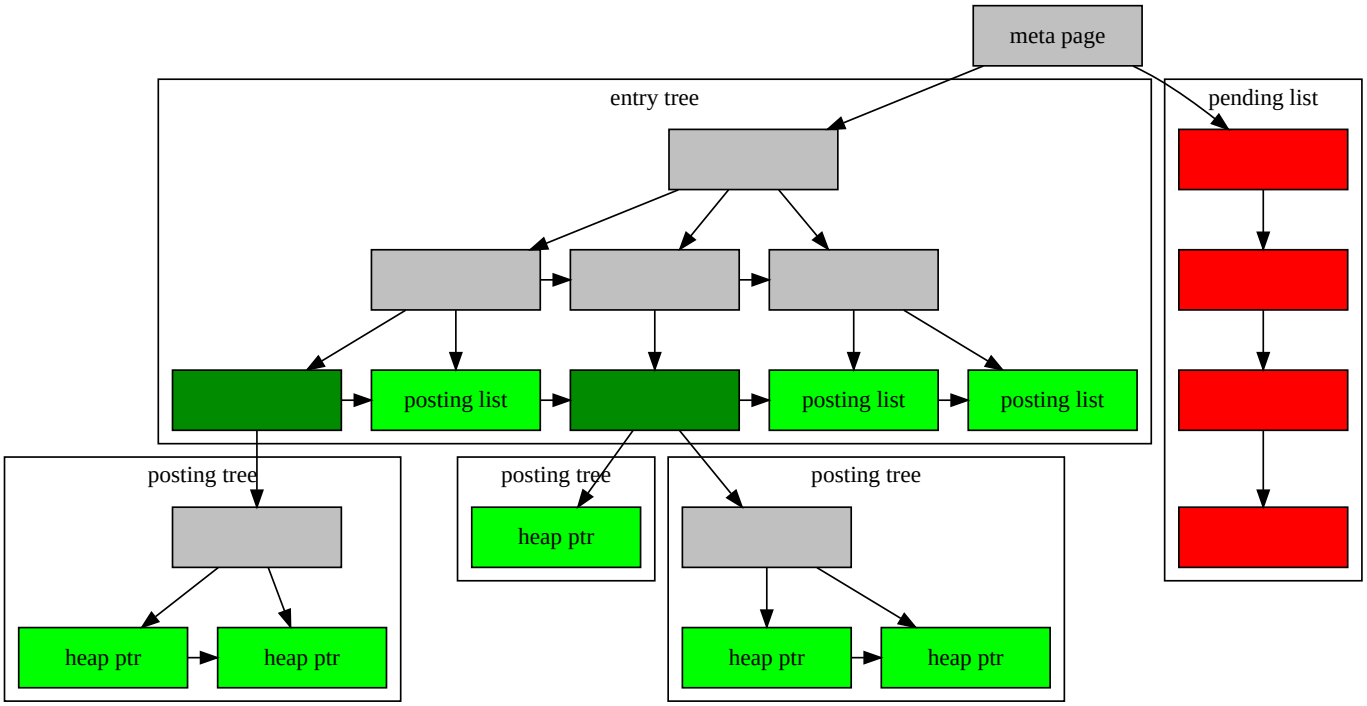
71.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value. Figure 71.1 illustrates these components of a GIN index.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

Figure 71.1. GIN Internals



71.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when `gin_clean_pending_list` function is called, or if the pending list becomes larger than gin_pending_list_limit, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See CREATE INDEX for details.

71.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

71.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

When `fastupdate` is enabled for GIN (see Section 71.4.1 for details), the penalty is less than when it is not. But for very large updates it may still be best to drop and recreate the index.

maintenance_work_mem

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

gin_pending_list_limit

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it's possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

gin_fuzzy_search_limit

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in Postgres Pro, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system's random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

71.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

71.7. Examples

The core Postgres Pro distribution includes the GIN operator classes previously shown in Table 71.1. The following `contrib` modules also contain GIN operator classes:

`btree_gin`

B-tree equivalent functionality for several data types

`hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int[]`

`pg_trgm`

Text similarity using trigram matching

Chapter 72. BRIN Indexes

72.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table.

BRIN works in terms of *block ranges* (or "page ranges"). A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is *consistent* with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

72.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, the range that the new page belongs to does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating the initial summary for that range.

There are several ways to trigger the initial summarization of a page range. If the table is vacuumed, either manually or by autovacuum, all existing unsummarized page ranges are summarized. Also, if the index's autosummarize parameter is enabled, which it isn't by default, whenever autovacuum runs in that database, summarization will occur for all unsummarized page ranges that have been filled, regardless of whether the table itself is processed by autovacuum; see below.

Lastly, the following functions can be used:

`brin_summarize_new_values(regclass)` which summarizes all unsummarized ranges;
`brin_summarize_range(regclass, bigint)` which summarizes only the range containing the given page, if it is unsummarized.

When autosummarization is enabled, a request is sent to `autovacuum` to execute a targeted summarization for a block range when an insertion is detected for the first item of the first page of the next block range, to be fulfilled the next time an autovacuum worker finishes running in the same database. If the request queue is full, the request is not recorded and a message is sent to the server log:

```
LOG:  request for BRIN range summarization for index "brin_wi_idx" page 128 was not
 recorded
```

When this happens, the range will remain unsummarized until the next regular vacuum run on the table, or one of the functions mentioned above are invoked.

Conversely, a range can be de-summarized using the `brin_desummarize_range(regclass, bigint)` function, which is useful when the index tuple is no longer a very good representation because the existing values have changed. See Section 9.27.8 for details.

72.2. Built-in Operator Classes

The core Postgres Pro distribution includes the BRIN operator classes shown in Table 72.1.

The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range. The *bloom* operator classes build a Bloom filter for all values in the range. The *minmax-multi* operator classes store multiple minimum and maximum values, representing values appearing in the indexed column within the range.

72.2.1. Operator Class Parameters

Some of the built-in operator classes allow specifying parameters affecting behavior of the operator class. Each operator class has its own set of allowed parameters. Only the `bloom` and `minmax-multi` operator classes allow specifying parameters:

bloom operator classes accept these parameters:

`n_distinct_per_range`

Defines the estimated number of distinct non-null values in the block range, used by BRIN bloom indexes for sizing of the Bloom filter. It behaves similarly to `n_distinct` option for ALTER TABLE. When set to a positive value, each block range is assumed to contain this number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, the number of distinct non-null values is assumed to grow linearly with the maximum possible number of tuples in the block range (about 290 rows per block). The default value is `-0.1`, and the minimum number of distinct non-null values is `16`.

`false_positive_rate`

Defines the desired false positive rate used by BRIN bloom indexes for sizing of the Bloom filter. The values must be between 0.0001 and 0.25. The default value is 0.01, which is 1% false positive rate.

minmax-multi operator classes accept these parameters:

`values_per_range`

Defines the maximum number of values stored by BRIN minmax indexes to summarize a block range. Each value may represent either a point, or a boundary of an interval. Values must be between 8 and 256, and the default value is 32.

72.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

`BrinOpcInfo *opcInfo(Oid type_oid)`

Returns internal information about the indexed columns' summary data. The return value must point to a palloc'd `BrinOpcInfo`, which has this definition:

```
typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this opclass */
    uint16      oi_nstored;

    /* Opaque pointer for the opclass' private use */
    void       *oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;
```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support functions during an index scan.

`bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey *keys, int nkeys)`

Returns whether all the ScanKey entries are consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. Multiple scan keys for the same attribute may be passed at once; the number of entries is determined by the `nkeys` parameter.

`bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)`

Returns whether the ScanKey is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. This is an older backward-compatible variant of the consistent function.

`bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)`

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

`bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)`

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

An operator class for BRIN can optionally specify the following method:

`void options(local_relopts *relopts)`

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in BRIN are flexible, they may depend on user-specified parameters.

The core distribution includes support for four types of operator classes: minmax, minmax-multi, inclusion and bloom. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support functions' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support functions described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support functions might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support functions alongside the corresponding operators, as shown in Table 72.2. All operator class members (functions and operators) are mandatory.

Table 72.2. Function and Support Numbers for Minmax Operator Classes

Operator class member	Object
Support Function 1	internal function `brin_minmax_opcinfo()`
Support Function 2	internal function `brin_minmax_add_value()`
Support Function 3	internal function `brin_minmax_consistent()`
Support Function 4	internal function `brin_minmax_union()`
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support functions alongside the corresponding operators, as shown in Table 72.3. It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

Table 72.3. Function and Support Numbers for Inclusion Operator Classes

Operator class member	Object	Dependency
Support Function 1	internal function `brin_inclusion_opcinfo()`	
Support Function 2	internal function `brin_inclusion_add_value()`	
Support Function 3	internal function `brin_inclusion_consistent()`	
Support Function 4	internal function `brin_inclusion_union()`	
Support Function 11	function to merge two elements	
Support Function 12	optional function to check whether two elements are mergeable	
Support Function 13	optional function to check if an element is contained within another	
Support Function 14	optional function to check whether an element is empty	
Operator Strategy 1	operator left-of	Operator Strategy 4
Operator Strategy 2	operator does-not-extend-to-the-right-of	Operator Strategy 5
Operator Strategy 3	operator overlaps	
Operator Strategy 4	operator does-not-extend-to-the-left-of	Operator Strategy 1
Operator Strategy 5	operator right-of	Operator Strategy 2

Operator class member	Object	Dependency
Operator Strategy 6, 18	operator same-as-or-equal-to	Operator Strategy 7
Operator Strategy 7, 16, 24, 25	operator contains-or-equal-to	
Operator Strategy 8, 26, 27	operator is-contained-by-or-equal-to	Operator Strategy 3
Operator Strategy 9	operator does-not-extend-above	Operator Strategy 11
Operator Strategy 10	operator is-below	Operator Strategy 12
Operator Strategy 11	operator is-above	Operator Strategy 9
Operator Strategy 12	operator does-not-extend-below	Operator Strategy 10
Operator Strategy 20	operator less-than	Operator Strategy 5
Operator Strategy 21	operator less-than-or-equal-to	Operator Strategy 5
Operator Strategy 22	operator greater-than	Operator Strategy 1
Operator Strategy 23	operator greater-than-or-equal-to	Operator Strategy 1

Support function numbers 1 through 10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the `STORAGE` parameter. The return value of the union function should match the `STORAGE` data type.

Support function numbers 12 and 14 are provided to support irregularities of built-in data types. Function number 12 is used to support network addresses from different families which are not mergeable. Function number 14 is used to support empty ranges. Function number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

To write an operator class for a data type that implements only an equality operator and supports hashing, it is possible to use the bloom support procedures alongside the corresponding operators, as shown in Table 72.4. All operator class members (procedures and operators) are mandatory.

Table 72.4. Procedure and Support Numbers for Bloom Operator Classes

Operator class member	Object
Support Procedure 1	internal function `brin_bloom_opcinfo()`
Support Procedure 2	internal function `brin_bloom_add_value()`
Support Procedure 3	internal function `brin_bloom_consistent()`
Support Procedure 4	internal function `brin_bloom_union()`
Support Procedure 5	internal function `brin_bloom_options()`
Support Procedure 11	function to compute hash of an element
Operator Strategy 1	operator equal-to

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept one argument with the same data type as the operator class, and return a hash of the value.

The minmax-multi operator class is also intended for data types implementing a totally ordered set, and may be seen as a simple extension of the minmax operator class. While minmax operator class summarizes values from each block range into a single contiguous interval, minmax-multi allows summarization into multiple smaller intervals to improve handling of outlier values. It is possible to use the

minmax-multi support procedures alongside the corresponding operators, as shown in Table 72.5. All operator class members (procedures and operators) are mandatory.

Table 72.5. Procedure and Support Numbers for minmax-multi Operator Classes

Operator class member	Object
Support Procedure 1	internal function `brin_minmax_multi_opcinfo()`
Support Procedure 2	internal function `brin_minmax_multi_add_value()`
Support Procedure 3	internal function `brin_minmax_multi_consistent()`
Support Procedure 4	internal function `brin_minmax_multi_union()`
Support Procedure 5	internal function `brin_minmax_multi_options()`
Support Procedure 11	function to compute distance between two values (length of a range)
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in Table 72.3, or the same operator strategy as themselves. They require the dependency operator to be defined with the `STORAGE` data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See `float4_minmax_ops` as an example of minmax, and `box_inclusion_ops` as an example of inclusion.

Chapter 73. Hash Indexes

73.1. Overview

Postgres Pro includes an implementation of persistent on-disk hash indexes, which are fully crash recoverable. Any data type can be indexed by a hash index, including data types that do not have a well-defined linear ordering. Hash indexes store only the hash value of the data being indexed, thus there are no restrictions on the size of the data column being indexed.

Hash indexes support only single-column indexes and do not allow uniqueness checking.

Hash indexes support only the = operator, so WHERE clauses that specify range operations will not be able to take advantage of hash indexes.

Each hash index tuple stores just the 4-byte hash value, not the actual column value. As a result, hash indexes may be much smaller than B-trees when indexing longer data items such as UUIDs, URLs, etc. The absence of the column value also makes all hash index scans lossy. Hash indexes may take part in bitmap index scans and backward scans.

Hash indexes are best optimized for SELECT and UPDATE-heavy workloads that use equality scans on larger tables. In a B-tree index, searches must descend through the tree until the leaf page is found. In tables with millions of rows, this descent can increase access time to data. The equivalent of a leaf page in a hash index is referred to as a bucket page. In contrast, a hash index allows accessing the bucket pages directly, thereby potentially reducing index access time in larger tables. This reduction in "logical I/O" becomes even more pronounced on indexes/data larger than shared_buffers/RAM.

Hash indexes have been designed to cope with uneven distributions of hash values. Direct access to the bucket pages works well if the hash values are evenly distributed. When inserts mean that the bucket page becomes full, additional overflow pages are chained to that specific bucket page, locally expanding the storage for index tuples that match that hash value. When scanning a hash bucket during queries, we need to scan through all of the overflow pages. Thus an unbalanced hash index might actually be worse than a B-tree in terms of number of block accesses required, for some data.

As a result of the overflow cases, we can say that hash indexes are most suitable for unique, nearly unique data or data with a low number of rows per hash bucket. One possible way to avoid problems is to exclude highly non-unique values from the index using a partial index condition, but this may not be suitable in many cases.

Like B-Trees, hash indexes perform simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's LP_DEAD bit is already set). If an insert finds no space is available on a page we try to avoid creating a new overflow page by attempting to remove dead index tuples. Removal cannot occur if the page is pinned at that time. Deletion of dead index pointers also occurs during VACUUM.

If it can, VACUUM will also try to squeeze the index tuples onto as few overflow pages as possible, minimizing the overflow chain. If an overflow page becomes empty, overflow pages can be recycled for reuse in other buckets, though we never return them to the operating system. There is currently no provision to shrink a hash index, other than by rebuilding it with REINDEX. There is no provision for reducing the number of buckets, either.

Hash indexes may expand the number of bucket pages as the number of rows indexed grows. The hash key-to-bucket-number mapping is chosen so that the index can be incrementally expanded. When a new bucket is to be added to the index, exactly one existing bucket will need to be "split", with some of its tuples being transferred to the new bucket according to the updated key-to-bucket-number mapping.

The expansion occurs in the foreground, which could increase execution time for user inserts. Thus, hash indexes may not be suitable for tables with rapidly increasing number of rows.

73.2. Implementation

There are four kinds of pages in a hash index: the meta page (page zero), which contains statically allocated control information; primary bucket pages; overflow pages; and bitmap pages, which keep track of overflow pages that have been freed and are available for re-use. For addressing purposes, bitmap pages are regarded as a subset of the overflow pages.

Both scanning the index and inserting tuples require locating the bucket where a given tuple ought to be located. To do this, we need the bucket count, highmask, and lowmask from the metapage; however, it's undesirable for performance reasons to have to have to lock and pin the metapage for every such operation. Instead, we retain a cached copy of the metapage in each backend's relcache entry. This will produce the correct bucket mapping as long as the target bucket hasn't been split since the last cache refresh.

Primary bucket pages and overflow pages are allocated independently since any given index might need more or fewer overflow pages relative to its number of buckets. The hash code uses an interesting set of addressing rules to support a variable number of overflow pages while not having to move primary bucket pages around after they are created.

Each row in the table indexed is represented by a single index tuple in the hash index. Hash index tuples are stored in bucket pages, and if they exist, overflow pages. We speed up searches by keeping the index entries in any one index page sorted by hash code, thus allowing binary search to be used within an index page. Note however that there is *no* assumption about the relative ordering of hash codes across different index pages of a bucket.

The bucket splitting algorithms to expand the hash index are too complex to be worthy of mention here. The split algorithm is crash safe and can be restarted if not completed successfully.

Chapter 74. Database Physical Storage

This chapter provides an overview of the physical storage format used by Postgres Pro databases.

74.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster's data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgpro/ent-16/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in Table 74.1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

Table 74.1. Contents of `PGDATA`

Item	Description
`PG_VERSION`	A file containing the major version number of Postgres Pro
`base`	Subdirectory containing per-database subdirectories
`current_logfiles`	File recording the log file(s) currently written to by the logging collector
`global`	Subdirectory containing cluster-wide tables, such as `pg_database`
`pg_commit_ts`	Subdirectory containing transaction commit timestamp data
`pg_dynshmem`	Subdirectory containing files used by the dynamic shared memory subsystem
`pg_logical`	Subdirectory containing status data for logical decoding
`pg_multixact`	Subdirectory containing multitransaction status data (used for shared row locks)
`pg_notify`	Subdirectory containing LISTEN/NOTIFY status data
`pg_replslot`	Subdirectory containing replication slot data
`pg_serial`	Subdirectory containing information about committed serializable transactions
`pg_snapshots`	Subdirectory containing exported snapshots
`pg_stat`	Subdirectory containing permanent files for the statistics subsystem
`pg_stat_tmp`	Subdirectory containing temporary files for the statistics subsystem
`pg_subtrans`	Subdirectory containing subtransaction status data
`pg_tblspc`	Subdirectory containing symbolic links to tablespaces
`pg_twophase`	Subdirectory containing state files for prepared transactions

Item	Description
pg_wal	Subdirectory containing WAL (Write Ahead Log) files
pg_xact	Subdirectory containing transaction commit status data
postgresql.auto.conf	A file used for storing configuration parameters that are set by ALTER SYSTEM
postmaster.opts	A file recording the command-line options the server was last started with
postmaster.pid	A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (could be empty), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)

For each database in the cluster there is a subdirectory within PGDATA/base, named after the database's OID in pg_database. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Note that the following sections describe the behavior of the builtin heap table access method, and the builtin index access methods. Due to the extensible nature of Postgres Pro, other access methods might work differently.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's *filenode* number, which can be found in pg_class.relfilenode. But for temporary relations, the file name is of the form t*BBB*_*FFF*, where *BBB* is the backend ID of the backend which created the file, and *FFF* is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a *free space map* (see Section 74.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix _fsm. Tables also have a *visibility map*, stored in a fork with the suffix _vm, to track which pages are known to have no dead tuples. The visibility map is described further in Section 74.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix _init (see Section 74.5).

> **Caution**
>
> Note that while a table's filenode often matches its OID, this is *not* necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including pg_class itself, pg_class.relfilenode contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the pg_relation_filenode() function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option --with-segsize when building Postgres Pro.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 74.2 for more information.

The contents of tables and indexes are discussed further in Section 74.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's `CREATE TABLESPACE` command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the Postgres Pro server version, such as `PG_9.0_201008051`. (The reason for using this subdirectory is so that successive versions of the database can use the same `CREATE TABLESPACE` location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

The `pg_relation_filepath()` function shows the entire path (relative to `PGDATA`) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or `_fsm`, `_vm`, or `_init` to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmp`*`PPP`*`.`*`NNN`*, where *`PPP`* is the PID of the owning backend and *`NNN`* distinguishes different temporary files of that backend.

74.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

Postgres Pro uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called *TOASTed values* work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been *detoasted*. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible. See Section 41.13.1 for more detail.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB (2^{30} - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line

data, with several possible alternatives as described below. The type and size of such a *TOAST pointer* are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

The compression technique used for either in-line or out-of-line compressed data can be selected for each column by setting the `COMPRESSION` column option in `CREATE TABLE` or `ALTER TABLE`. The default for columns with no explicit setting is to consult the default_toast_compression parameter at the time data is inserted.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a *TOAST table* that is separate from, but associated with, the table containing the TOAST pointer datum itself. These *on-disk* pointer datums are created by the TOAST management code when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 74.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 74.2.2.

74.2.1. Out-of-Line, On-Disk TOAST Storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length), physical stored size (different if compression was applied), and the compression method used, if any. Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB, adjustable) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- `PLAIN` prevents either compression or out-of-line storage. This is the only possible strategy for columns of non-TOAST-able data types.
- `EXTENDED` allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- `EXTERNAL` allows out-of-line storage but not compression. Use of `EXTERNAL` will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.

- `MAIN` allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

`TOAST_TUPLE_TARGET` can be adjusted for each table using `ALTER TABLE ... SET (toast_tuple_target = N)`

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

74.2.2. Out-of-Line, In-Memory TOAST Storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a Postgres Pro array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the *N*'th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an “expanded” or “deconstructed” representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in *src/include/utils/expandeddatum.h*. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into *read-write* and *read-only* pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to

normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

74.2.3. Pluggable TOAST

TOAST is a part of Postgres Pro core. TOAST is not extensible, has the same strategy for all data types and is not effective for structured data (JSON) or data that requires a special workflow (`bytea`).

Experimental pluggable TOAST provides an open API allowing you to develop and plug in custom TOAST implementations for table columns and data types in addition to the default one. These implementations are called TOASTers. A TOASTer can process TOASTed data using the knowledge about the internal data structure and workflow.

TOASTers can use any storage, advanced compression, encryption and other functionalities internally, without being aware of the table access method that calls the TOASTer.

The pluggable TOAST consists of the core, that is, the TOAST API, and custom TOASTers plugged in to Postgres Pro with this API.

This API does not possess any logic regarding the TOAST functionality, it is just a wraparound that allows registering, calling and dropping plugged TOASTers.

To enable using custom TOAST implementations, the TOAST API defines a new `Custom` type of TOAST pointer in addition to `External` and `Extended` (corresponding to `EXTERNAL` and `EXTENDED` TOAST-able column storing strategies).

Currently the pluggable TOAST has several limitations:

- Custom TOASTers must only be assigned to a column with the `EXTERNAL` storing strategy.
- Currently the pluggable TOAST does not support logical replication. A custom TOAST pointer is skipped by the logical replication engine and is not replicated. This is because support of custom pointers requires heavy modifications in the Postgres Pro core (the logical replication engine) and even architecture changes as now custom pointers allow updating TOASTed values, while default pointers do not.
- Custom TOASTers are not restored from dumps and require manual actions for restoring. The TOASTer extension is not restored from dump, thus the data processed with it are not available. Another point is that the same TOASTer extension has different IDs in different systems, so restoring a TOASTed value from dump would require determining the TOASTer used for processing data.
- When a custom TOASTer is assigned to a table column, in all the transactions after the TOASTer assignment, data being stored in the TOAST tables is processed with the TOASTer assigned to the column.
- When a custom TOASTer is assigned to a table column, old data values are left as-is and are not re-TOASTed although while being updated, an old data value is TOASTed with the assigned TOASTer because of the workflow of the default TOAST mechanics.
- If the TOASTer is somehow dropped, the data TOASTed with it will not be accessible with any standard techniques and is considered to be lost. To protect TOASTed values, the API creates some dependencies in the system (`PG_DEPEND` table):
  - When the TOASTer is added to a system, a TOASTer-extension dependency is created.
  - When the TOASTer is assigned to a column, a TOASTer-relation dependency is created.
  - When the TOASTer is unassigned from a column, the TOASTer-relation dependency is deleted.
  - When the TOASTer is dropped from a system, the TOASTer-extension dependency is deleted.

Custom TOASTers are added as extensions implementing some mandatory functions (check `README.toastapi` file in `/contrib/toastapi` for more details). Pluggable TOAST provides a set of SQL functions to control custom TOASTers. These functions are called with SQL `SELECT` command:

`add_toaster(`*`toaster_name`* `text, `*`toaster_handler_func`* `text) → integer`

Plug in a new TOASTer (added before as an extension). This function also creates a dependency in `PG_DEPEND` for the TOASTer OID to its extension OID, which is used to protect the TOASTer from being dropped when dropping the TOASTer extension.

Arguments:

- *`toaster_name`* — TOASTer name to be stored in `PG_TOASTER`. Must be unique.
- *`toaster_handler_func`* — TOASTer handler function name (automatically added as a `regproc` when the TOASTer extension is installed).

Returns OID assigned to the new TOASTer.

`set_toaster(`*`toaster_name`* `text, `*`tab_name`* `text, `*`col_name`* `text) → integer`

Assign a TOASTer to a table column. This function also creates a dependency in `PG_DEPEND` for the TOASTer OID to the relation OID. This dependency is used to protect TOASTed data by restricting dropping the TOASTer that is assigned to a column.

Arguments:

- *`toaster_name`* — name of the TOASTer assigned to a table column.
- *`tab_name`* — table name.
- *`col_name`* — column name.

Returns OID of the TOASTer assigned to the column.

`reset_toaster(`*`tab_name`* `text, `*`col_name`* `text) → integer`

Reset the TOAST mechanism to a default one for a table column. This function drops the TOASTer-relation dependency, which allows dropping the TOASTer later, when all depencencies are dropped.

Arguments:

- *`tab_name`* — table name.
- *`col_name`* — table column name.

Returns always 0.

`drop_toaster(`*`toaster_name`* `text)`

Drop a TOASTer from the system. Only unused TOASTers, which do not have any data TOASTed with them can be dropped. Dropping is protected by the dependencies created by `add_toaster` and `set_toaster` functions. If a dependency still exists, the TOASTer would not be dropped. If the TOASTer was dropped successfully, the extension with its implementation can be dropped by the `DROP EXTENSION` command.

Arguments:

- *`toaster_name`* — name of the TOASTer to be dropped.

Returns the TOASTer OID on success or 0 if the TOASTer is used.

`get_toaster(`*`tab_name`* `text, `*`col_name`* `text) → integer`

Get the OID of the TOASTer assigned to a table column.

Arguments:

- *`tab_name`* — table name.
- *`col_name`* — table column name.

Returns the OID of the TOASTer assigned to a column or 0 if none.

The following example illustrates the use of the pluggable TOAST API:

```
CREATE EXTENSION toastapi;

CREATE EXTENSION bytea_toaster;

SELECT add_toaster('bytea_toaster');

CREATE TABLE test_bytea_append (id int, a bytea);

ALTER TABLE test_bytea_append ALTER a SET STORAGE external;

SELECT set_toaster('bytea_toaster', 'test_bytea_append', 'a');
 test_set_toaster
------------------

(1 row)

...

SELECT get_toaster('test_bytea_append', 'a') AS bytea_toaster_oid;
 get_toaster
-------------
        16348
(1 row)

SELECT pgpro_toast.reset_toaster('test_bytea_append','a');
 reset_toaster
---------------
             0
(1 row)

DROP TABLE test_bytea_append;
SELECT pgpro_toast.drop_toaster('bytea_toaster');
 drop_toaster
--------------
         16348
(1 row)

DROP EXTENSION bytea_toaster;
```

74.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

The pg_freespacemap module can be used to examine the information stored in free space maps.

74.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by *index-only scans* to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The pg_visibility module can be used to examine the information stored in the visibility map.

74.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

74.6. Database Page Layout

This section provides an overview of the page format used within Postgres Pro tables and indexes.[1] Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 74.2 shows the overall layout of a page. There are five parts to each page.

Table 74.2. Overall Page Layout

Item	Description
PageHeaderData	24 bytes long. Contains general information about the page, including free space pointers.
ItemIdData	Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.
Free space	The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.

[1] Actually, use of this page format is not required for either table or index access methods. The `heap` table access method always uses this format. All the existing index methods also use the basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

Item	Description
Items	The actual items themselves.
Special space	Index access method specific data. Different methods store different data. Additionally, this space is used to store information about 64-bit transaction IDs.

The first 20 bytes of each page consists of a page header (`PageHeaderData`). Its format is detailed in Table 74.3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (`pd_lower`, `pd_upper`, and `pd_special`). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, `pd_pagesize_version`, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation.

Table 74.3. PageHeaderData Layout

Field	Type	Length	Description
pd_lsn	PageXLogRecPtr	8 bytes	LSN: next byte after last byte of WAL record for last change to this page
pd_checksum	uint16	2 bytes	Page checksum
pd_flags	uint16	2 bytes	Flag bits
pd_lower	LocationIndex	2 bytes	Offset to start of free space
pd_upper	LocationIndex	2 bytes	Offset to end of free space
pd_special	LocationIndex	2 bytes	Offset to start of special space
pd_pagesize_version	uint16	2 bytes	Page size and layout version number information

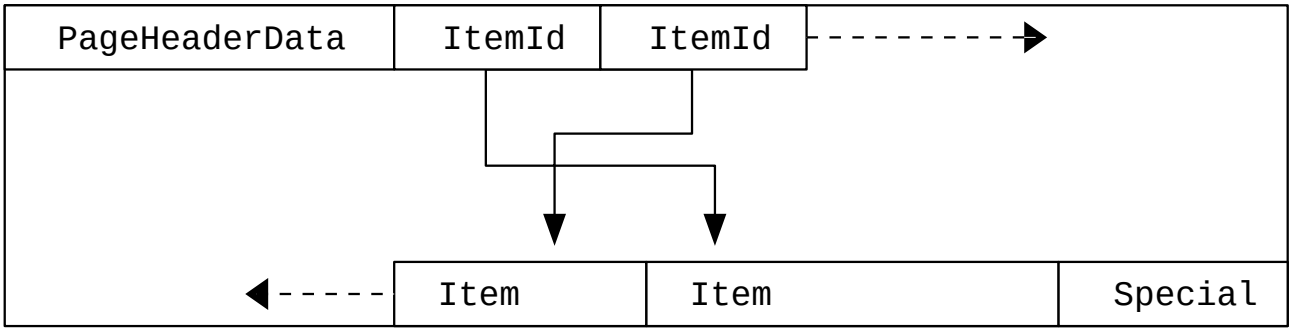
Following the page header are item identifiers (`ItemIdData`), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (`ItemPointer`, also known as `CTID`) created by Postgres Pro consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named `HeapTupleHeaderData`, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page's left and right siblings, as well as some other data relevant to the index structure. Ordinary tables and sequences store the `HeapPageSpecialData` structure in this section. Its format is specified in Table 74.4.

Figure 74.1 illustrates how these parts are laid out in a page.

Figure 74.1. Page Layout



74.6.1. Table Row Layout

`HeapPageSpecialData` is a 24-byte structure. The first two 8-byte fields contain the base (i.e., an offset) for short (4-byte) transaction IDs in this page. The next field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page. The last field is a magic number identifying the type of the page (`0x1010` for ordinary tables and `0x1717` for sequences).

Table 74.4. HeapPageSpecialData Layout

Field	Type	Length	Description
pd_xid_base	TransactionId	8 bytes	Base for short 4-byte transaction IDs in this page
pd_multi_base	TransactionId	8 bytes	Base for short 4-byte multixact IDs in this page
pd_prune_xid	ShortTransactionId	4 bytes	Oldest unpruned XMAX on page, or zero if none
pd_magic	uint32	4 bytes	Magic number identifying the type of this page

All table rows are structured in the same way. There is a fixed-size header (occupying 40 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 74.5. The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the MAXALIGN distance for the platform. The null bitmap is only present if the *HEAP_HASNULL* bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, the number of bits that equals the attribute count in `t_infomask2`). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the *HEAP_HASOID_OLD* bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a MAXALIGN multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 74.5. HeapTupleHeaderData Layout

Field	Type	Length	Description
t_xmin	ShortTransactionId	4 bytes	insert XID stamp

Field	Type	Length	Description
t_xmax	ShortTransactionId	4 bytes	delete XID stamp
t_cid	CommandId	4 bytes	insert and/or delete CID stamp (overlays with t_xvac)
t_xvac	ShortTransactionId	4 bytes	XID for VACUUM operation moving a row version
t_ctid	ItemPointerData	6 bytes	current TID of this or newer row version
t_infomask2	uint16	2 bytes	number of attributes, plus various flag bits
t_infomask	uint16	2 bytes	various flag bits
t_hoff	uint8	1 byte	offset to user data

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions *heap_getattr*, *fastgetattr* and *heap_getsysattr*.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (attlen = -1) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 74.2).

74.7. Heap-Only Tuples (HOT)

To allow for high concurrency, Postgres Pro uses multiversion concurrency control (MVCC) to store rows. However, MVCC has some downsides for update queries. Specifically, updates require new versions of rows to be added to tables. This can also require new index entries for each updated row, and removal of old versions of rows and their index entries can be expensive.

To help reduce the overhead of updates, Postgres Pro has an optimization called heap-only tuples (HOT). This optimization is possible when:

- The update does not modify any columns referenced by the table's indexes, not including summarizing indexes. The only summarizing index method in the core PostgreSQL distribution is BRIN.
- There is sufficient free space on the page containing the old row for the updated row.

In such cases, heap-only tuples provide two optimizations:

- New index entries are not needed to represent updated rows, however, summary indexes may still need to be updated.
- Old versions of updated rows can be completely removed during normal operation, including `SELECT`s, instead of requiring periodic vacuum operations. (This is possible because indexes do not reference their page item identifiers.)

You can increase the likelihood of sufficient page space for HOT updates by decreasing a table's `fillfactor`. If you don't, HOT updates will still happen because new rows will naturally migrate to new pages and existing pages with sufficient free space for new row versions. The system view pg_stat_all_tables allows monitoring of the occurrence of HOT and non-HOT updates.

Chapter 75. Transaction Processing

This chapter provides an overview of the internals of Postgres Pro's transaction management system. The word transaction is often abbreviated as *xact*.

75.1. Transactions and Identifiers

Transactions can be created explicitly using `BEGIN` or `START TRANSACTION` and ended using `COMMIT` or `ROLLBACK`. SQL statements outside of explicit transactions automatically use single-statement transactions.

Every transaction is identified by a unique `VirtualTransactionId` (also called `virtualXID` or `vxid`), which is comprised of a backend ID (or `backendID`) and a sequentially-assigned number local to each backend, known as `localXID`. For example, the virtual transaction ID `4/12532` has a `backendID` of `4` and a `localXID` of `12532`.

Non-virtual `TransactionId`s (or `xid`), e.g., `278394`, are assigned sequentially to transactions from a global counter used by all databases within the Postgres Pro cluster. This assignment happens when a transaction first writes to the database. This means lower-numbered xids started writing before higher-numbered xids. Note that the order in which transactions perform their first database write might be different from the order in which the transactions started, particularly if the transaction started with statements that only performed database reads.

In Postgres Pro Enterprise, the internal transaction ID type `xid` is 64 bits wide to prevent transaction ID wraparound. Each tuple header contains two XIDs, so extending them would lead to high overhead. For that reason, when saved on disk on-tuple XIDs are 32-bit, but each page special area contains an offset, called *base XID*. When a tuple is read into memory, the base XID is added to its 32-bit XIDs, and both XIDs in the tuple become full 64 bits wide so the tuple becomes the so-called in-memory tuple. Full 64-bit XIDs acquired after adding the base XID are used in comparison and other arithmetic operations. In some contexts, `xid8` is also used. The functions in Table 9.81 return `xid8` values. Xids are used as the basis for Postgres Pro's MVCC concurrency mechanism and streaming replication.

When a top-level transaction with a (non-virtual) xid commits, it is marked as committed in the `pg_xact` directory. Additional information is recorded in the `pg_commit_ts` directory if track_commit_timestamp is enabled.

In addition to `vxid` and `xid`, prepared transactions are also assigned Global Transaction Identifiers (GID). GIDs are string literals up to 200 bytes long, which must be unique amongst other currently prepared transactions. The mapping of GID to xid is shown in `pg_prepared_xacts`.

75.2. Transactions and Locking

The transaction IDs of currently executing transactions are shown in `pg_locks` in columns `virtualxid` and `transactionid`. Read-only transactions will have `virtualxid`s but NULL `transactionid`s, while both columns will be set in read-write transactions.

Some lock types wait on `virtualxid`, while other types wait on `transactionid`. Row-level read and write locks are recorded directly in the locked rows and can be inspected using the pgrowlocks extension. Row-level read locks might also require the assignment of multixact IDs (`mxid`; see Section 24.1.5.1).

75.3. Subtransactions

Subtransactions are started inside transactions, allowing large transactions to be broken into smaller units. Subtransactions can commit or abort without affecting their parent transactions, allowing parent transactions to continue. This allows errors to be handled more easily, which is a common application development pattern. The word subtransaction is often abbreviated as *subxact*.

Subtransactions can be started explicitly using the `SAVEPOINT` command, but can also be started in other ways, such as PL/pgSQL's `EXCEPTION` clause. PL/Python and PL/Tcl also support explicit subtransactions.

Subtransactions can also be started from other subtransactions. The top-level transaction and its child subtransactions form a hierarchy or tree, which is why we refer to the main transaction as the top-level transaction.

If a subtransaction is assigned a non-virtual transaction ID, its transaction ID is referred to as a “subxid”. In Postgres Pro Enterprise, subxids are 64 bits wide. Read-only subtransactions are not assigned subxids, but once they attempt to write, they will be assigned one. This also causes all of a subxid's parents, up to and including the top-level transaction, to be assigned non-virtual transaction ids. We ensure that a parent xid is always lower than any of its child subxids.

The immediate parent xid of each subxid is recorded in the `pg_subtrans` directory. No entry is made for top-level xids since they do not have a parent, nor is an entry made for read-only subtransactions.

When a subtransaction commits, all of its committed child subtransactions with subxids will also be considered subcommitted in that transaction. When a subtransaction aborts, all of its child subtransactions will also be considered aborted.

When a top-level transaction with an xid commits, all of its subcommitted child subtransactions are also persistently recorded as committed in the `pg_xact` subdirectory. If the top-level transaction aborts, all its subtransactions are also aborted, even if they were subcommitted.

The more subtransactions each transaction keeps open (not rolled back or released), the greater the transaction management overhead. Up to 64 open subxids are cached in shared memory for each backend; after that point, the storage I/O overhead increases significantly due to additional lookups of subxid entries in `pg_subtrans`.

75.4. Two-Phase Transactions

Postgres Pro supports a two-phase commit (2PC) protocol that allows multiple distributed systems to work together in a transactional manner. The commands are `PREPARE TRANSACTION`, `COMMIT PREPARED` and `ROLLBACK PREPARED`. Two-phase transactions are intended for use by external transaction management systems. Postgres Pro follows the features and model proposed by the X/Open XA standard, but does not implement some less often used aspects.

When the user executes `PREPARE TRANSACTION`, the only possible next commands are `COMMIT PREPARED` or `ROLLBACK PREPARED`. In general, this prepared state is intended to be of very short duration, but external availability issues might mean transactions stay in this state for an extended interval. Short-lived prepared transactions are stored only in shared memory and WAL. Transactions that span checkpoints are recorded in the `pg_twophase` directory. Transactions that are currently prepared can be inspected using `pg_prepared_xacts`.

Chapter 76. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

76.1. Row Estimation Examples

The examples shown below use tables in the Postgres Pro regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;

                         QUERY PLAN
-------------------------------------------------------------
 Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';

 relpages | reltuples
----------+-----------
      358 |     10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;

                                 QUERY PLAN
-----------------------------------------------------------------------------
 Bitmap Heap Scan on tenk1  (cost=24.06..394.64 rows=1007 width=244)
   Recheck Cond: (unique1 < 1000)
   ->  Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)
         Index Cond: (unique1 < 1000)
```

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarltsel`. The `scalarltsel` function retrieves the histogram for `unique1` from `pg_statistic`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';

                    histogram_bounds
------------------------------------------------------
 {0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}
```

Next the fraction of the histogram occupied by "< 1000" is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993–1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
            = (1 + (1000 - 993)/(1997 - 993))/10
            = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
     = 10000 * 0.100697
     = 1007  (rounding off)
```

Next let's consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';

                        QUERY PLAN
-----------------------------------------------------------
 Seq Scan on tenk1  (cost=0.00..483.00 rows=30 width=244)
   Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';

null_frac         | 0
n_distinct        | 676
most_common_vals  | {EJAAAA,BBAAAA,CRAAAA,FCAAAA,FEAAAA,GSAAAA,
JOAAAA,MCAAAA,NAAAAA,WGAAAA}
most_common_freqs | {0.00333333,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003}
```

Since `CRAAAA` appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```
selectivity = mcf[3]
            = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```
rows = 10000 * 0.003
     = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';

                        QUERY PLAN
-----------------------------------------------------------
 Seq Scan on tenk1  (cost=0.00..483.00 rows=15 width=244)
   Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```
selectivity = (1 - sum(mcv_freqs))/(num_distinct - num_mcv)
            = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 +
                    0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
            = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```
rows = 10000 * 0.0014559
     = 15  (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., "< 1000") to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';

                          QUERY PLAN
-------------------------------------------------------------
 Seq Scan on tenk1  (cost=0.00..483.00 rows=3077 width=244)
   Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';

                                histogram_bounds
------------------------------------------------------------------------------
 {AAAAAA,CQAAAA,FRAAAA,IBAAAA,KRAAAA,NFAAAA,PSAAAA,SGAAAA,VAAAAA,XLAAAA,ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
            = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
            = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
            = 0.01833333 + 0.298387 * 0.96966667
            = 0.307669

rows        = 10000 * 0.307669
            = 3077  (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';

                                     QUERY PLAN
-------------------------------------------------------------------------------
 Bitmap Heap Scan on tenk1  (cost=23.80..396.91 rows=1 width=244)
   Recheck Cond: (unique1 < 1000)
   Filter: (stringu1 = 'xxx'::name)
   ->  Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)
         Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 = 'xxx')
            = 0.100697 * 0.0014559
            = 0.0001466

rows        = 10000 * 0.0001466
            = 1  (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

                                      QUERY PLAN
--------------------------------------------------------------------------------
 Nested Loop  (cost=4.64..456.23 rows=50 width=488)
   ->  Bitmap Heap Scan on tenk1 t1  (cost=4.64..142.17 rows=50 width=244)
         Recheck Cond: (unique1 < 50)
         ->  Bitmap Index Scan on tenk1_unique1  (cost=0.00..4.63 rows=50 width=0)
               Index Cond: (unique1 < 50)
   ->  Index Scan using tenk2_unique2 on tenk2 t2  (cost=0.00..6.27 rows=1 width=244)
         Index Cond: (unique2 = t1.unique2)
```

The restriction on `tenk1`, `unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

```
selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max - bucket[1].min))/num_buckets
            = (0 + (50 - 0)/(993 - 0))/10
            = 0.005035

rows        = 10000 * 0.005035
            = 50  (rounding off)
```

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar `=`, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```
SELECT tablename, null_frac,n_distinct, most_common_vals FROM pg_stats
```

```
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';

tablename  | null_frac | n_distinct | most_common_vals
-----------+-----------+------------+------------------
 tenk1     |         0 |         -1 |
 tenk2     |         0 |         -1 |
```

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

```
selectivity = (1 - null_frac1) * (1 - null_frac2) * min(1/num_distinct1, 1/
num_distinct2)
            = (1 - 0) * (1 - 0) / max(10000, 10000)
            = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```
rows = (outer_cardinality * inner_cardinality) * selectivity
     = (50 * 10000) * 0.0001
     = 50
```

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from 50 * 1, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

76.2. Multivariate Statistics Examples

76.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```
CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1, 10000) s(i);
ANALYZE t;
```

As explained in Section 14.2, the planner can determine cardinality of `t` using the number of pages and rows obtained from `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';

 relpages | reltuples
----------+-----------
       45 |     10000
```

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a `WHERE` condition on the `a` column:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1;
                                  QUERY PLAN
-------------------------------------------------------------------------------
```

```
 Seq Scan on t  (cost=0.00..170.00 rows=100 width=8) (actual rows=100 loops=1)
   Filter: (a = 1)
   Rows Removed by Filter: 9900
```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the `WHERE` condition to use the `b` column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with `AND`:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
                                 QUERY PLAN
-----------------------------------------------------------------------------
 Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=100 loops=1)
   Filter: ((a = 1) AND (b = 1))
   Rows Removed by Filter: 9900
```

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs `ANALYZE` to calculate functional-dependency multivariate statistics on the two columns:

```
CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
                                 QUERY PLAN
-----------------------------------------------------------------------------
 Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
   Filter: ((a = 1) AND (b = 1))
   Rows Removed by Filter: 9900
```

76.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a `GROUP BY` clause. When `GROUP BY` lists a single column, the n-distinct estimate (which is visible as the estimated number of rows returned by the HashAggregate node) is very accurate:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a;
                                      QUERY PLAN
-----------------------------------------------------------------------
----------------------
 HashAggregate  (cost=195.00..196.00 rows=100 width=12) (actual rows=100 loops=1)
   Group Key: a
   ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=4) (actual rows=10000
 loops=1)
```

But without multivariate statistics, the estimate for the number of groups in a query with two columns in `GROUP BY`, as in the following example, is off by an order of magnitude:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
                                      QUERY PLAN
-----------------------------------------------------------------------
-------------------------
 HashAggregate  (cost=220.00..230.00 rows=1000 width=16) (actual rows=100 loops=1)
   Group Key: a, b
   ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
 loops=1)
```

By redefining the statistics object to include n-distinct counts for the two columns, the estimate is much improved:

```
DROP STATISTICS stts;
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
                                            QUERY PLAN
---------------------------------------------------------------------------
-------------------------
 HashAggregate  (cost=220.00..221.00 rows=100 width=16) (actual rows=100 loops=1)
   Group Key: a, b
   ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
 loops=1)
```

76.2.3. MCV Lists

As explained in Section 76.2.1, functional dependencies are very cheap and efficient type of statistics, but their main limitation is their global nature (only tracking dependencies at the column level, not between individual column values).

This section introduces multivariate variant of MCV (most-common values) lists, a straightforward extension of the per-column statistics described in Section 76.1. These statistics address the limitation by storing individual values, but it is naturally more expensive, both in terms of building the statistics in `ANALYZE`, storage and planning time.

Let's look at the query from Section 76.2.1 again, but this time with a MCV list created on the same set of columns (be sure to drop the functional dependencies, to make sure the planner uses the newly created statistics).

```
DROP STATISTICS stts;
CREATE STATISTICS stts2 (mcv) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
                                      QUERY PLAN
---------------------------------------------------------------------------------
 Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
   Filter: ((a = 1) AND (b = 1))
   Rows Removed by Filter: 9900
```

The estimate is as accurate as with the functional dependencies, mostly thanks to the table being fairly small and having a simple distribution with a low number of distinct values. Before looking at the second query, which was not handled by functional dependencies particularly well, let's inspect the MCV list a bit.

Inspecting the MCV list is possible using `pg_mcv_list_items` set-returning function.

```
SELECT m.* FROM pg_statistic_ext join pg_statistic_ext_data on (oid = stxoid),
                pg_mcv_list_items(stxdmcv) m WHERE stxname = 'stts2';
 index |  values  | nulls | frequency | base_frequency
-------+----------+-------+-----------+----------------
     0 | {0, 0}   | {f,f} |      0.01 |         0.0001
     1 | {1, 1}   | {f,f} |      0.01 |         0.0001
   ...
    49 | {49, 49} | {f,f} |      0.01 |         0.0001
    50 | {50, 50} | {f,f} |      0.01 |         0.0001
   ...
    97 | {97, 97} | {f,f} |      0.01 |         0.0001
    98 | {98, 98} | {f,f} |      0.01 |         0.0001
    99 | {99, 99} | {f,f} |      0.01 |         0.0001
(100 rows)
```

This confirms there are 100 distinct combinations in the two columns, and all of them are about equally likely (1% frequency for each one). The base frequency is the frequency computed from per-column

statistics, as if there were no multi-column statistics. Had there been any null values in either of the columns, this would be identified in the `nulls` column.

When estimating the selectivity, the planner applies all the conditions on items in the MCV list, and then sums the frequencies of the matching ones.

Compared to functional dependencies, MCV lists have two major advantages. Firstly, the list stores actual values, making it possible to decide which combinations are compatible.

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 10;
                                 QUERY PLAN
-----------------------------------------------------------------------------
 Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
   Filter: ((a = 1) AND (b = 10))
   Rows Removed by Filter: 10000
```

Secondly, MCV lists handle a wider range of clause types, not just equality clauses like functional dependencies. For example, consider the following range query for the same table:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a <= 49 AND b > 49;
                                 QUERY PLAN
-----------------------------------------------------------------------------
 Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
   Filter: ((a <= 49) AND (b > 49))
   Rows Removed by Filter: 10000
```

76.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules.

Chapter 77. Real-Time Query Replanning

Real-time query replanning enables replanning a query if during the query execution, some trigger indicates a non-optimal execution, so a more optimal plan should be looked for.

Real-time query replanning is disabled by default and can be enabled with the configuration parameter replan_enable.

Replanning currently has the following limitations:

- Cursors are not supported.
- `SELECT` statements are only supported except `SELECT FOR UPDATE` and `SELECT FOR SHARE`.
- Statements with volatile functions are not supported.

77.1. How It Works

If a replan trigger fires during query execution, the partially executed query is paused, and real-time query replanning attempts to reoptimize it. Information about the query statement, node cardinalities of non-parameterized nodes and parameterized nodes with actual cardinalities larger than predicted is used to choose a new plan and is stored for further reoptimizations. Then the query is rerun using the new plan. Replan triggers may be disabled for future reoptimizations of the same query in the following situations:

- No new information was gathered during execution. In this case, the output of `EXPLAIN ANALYZE` includes the text: `Replan Deactivation Reason: no new learning data`.
- The newly generated plan matches a plan that was already tried. In this case, the output of `EXPLAIN ANALYZE` includes the text: `Replan Deactivation Reason: repeated plan`.
- The maximum number of reruns, set by the replan_max_attempts configuration parameter, was reached. In this case, the output of `EXPLAIN ANALYZE` includes the text: `Replan Deactivation Reason: attempt limit reached`.
- An extension, such as pgpro_multiplan, disabled triggers. In this case, the output of `EXPLAIN ANALYZE` includes the text: `Replan Deactivation Reason: external deactivation`.

In such cases, the query execution continues without interruption.

If a replan trigger is activated, a query that meets the trigger condition is executed in an implicitly created subtransaction. In the event of replanning, this helps in cleaning up after a previous execution and releasing system resources, such as memory or disc space.

When using the pgpro_multiplan extension, you can collect statistics for all statements considered feasible for reoptimization.

77.1.1. Replan Triggers

The following triggers can interrupt a query and launch replanning:

- Query execution time: the trigger fires when the query runs longer than the value of the replan_query_execution_time configuration parameter.
- Number of processed node tuples: the trigger fires when this number exceeds the number normally expected by the planner, which is multiplied by the value of the replan_overrun_limit configuration parameter.
- Backend memory consumption: the trigger fires when memory consumption of a backend exceeds the value of the replan_memory_limit configuration parameter and the number of processed node tuples trigger fired.
- Manual trigger: the trigger fires when the user calls `replan_signal` from another session. Unlike other triggers, this trigger cannot be deactivated.

When using the pgpro_multiplan extension, you can override replanning trigger values specified by global configuration parameters for individual queries.

77.1.2. Viewing Replanning Details

If replan_show_signature is on, information related to replanning is included in the `EXPLAIN ANALYZE` output. The `SUMMARY` section additionally includes the following characteristics:

- `Replan Active` — whether replanning was active by the end of the query execution.
- `Table Entries` — number of tables in the query, including subqueries.
- `Controlled Statements` — number of statements that were replanned during execution of the query.
- `Replanning Attempts` — total number of the query reruns/replanning attempts.
- `Total Time Elapsed` — total time of the query execution including the time of all reruns/replanning attempts. This property is only displayed if the query was reoptimized and rerun at least once.
- `Final Run Planning Time` — planning time during last replanning reoptimization. This property is only displayed if the query was reoptimized and rerun at least once.
- `Replan Deactivation Reason` — what caused replanning to be disabled. Possible values are self-explanatory: `attempt limit reached`, `repeated plan`, `no new learning data`, or `external deactivation`. Displayed only if replanning was not active by the end of the query execution.

For each plan node, the following characteristics are included:

- `NodeSign` — a 64-bit signature (hash) of the node that uniquely identifies the node of the query plan. Not all nodes are signed, but only those where errors of the optimizer estimation model can cause errors in searching the optimal query plan.
- `Cardinality` — cardinality of the plan node achieved in previous executions of the query. Only available with the `VERBOSE` parameter.
- `Groups Number` — number of groups computed for this plan node from previous executions of the query. Only available with the `VERBOSE` parameter.

77.1.3. Example

Example 77.1. Using Replanning

The following example illustrates replanning:

```
DROP TABLE IF EXISTS replan_test;
CREATE TABLE replan_test WITH (autovacuum_enabled=off) AS
SELECT x as x, x as y, x as z from generate_series(1, 100000) as x;
INSERT INTO replan_test SELECT 1, x, x FROM generate_series(1, 1000000) as x;

CREATE INDEX ON replan_test(x);
CREATE INDEX ON replan_test(y);
ANALYZE;

set replan_show_signature = true;

-- Replanning is disabled
SET replan_enable = false;
EXPLAIN ANALYZE
SELECT FROM replan_test t1, replan_test t2, replan_test t3
WHERE t1.x = t2.x and
t1.y = t3.y and
t1.y < 100 and t1.z < 100 and
t2.y < 100 and t2.z < 100 and
```

```
 t3.y < 100 and t3.z < 100;

 -- Replanning is enabled with node tuples underestimation trigger
 SET replan_enable = true;
 SET replan_overrun_limit = 2;
 EXPLAIN ANALYZE
 SELECT FROM replan_test t1, replan_test t2, replan_test t3
 WHERE t1.x = t2.x and
 t1.y = t3.y and
 t1.y < 100 and t1.z < 100 and
 t2.y < 100 and t2.z < 100 and
 t3.y < 100 and t3.z < 100;
```

Output without replanning:

```
                                                                                QUERY PLAN
-------------------------------------------------------------------------------------------------------------------------
 Nested Loop  (cost=14.30..45.18 rows=1 width=0) (actual time=73.677..6848.136
 rows=20196 loops=1)
   ->  Nested Loop  (cost=13.87..36.72 rows=1 width=4) (actual time=73.654..6792.731
 rows=10098 loops=1)
         ->  Index Scan using replan_test_y_idx on replan_test t1  (cost=0.43..19.25
 rows=1 width=8) (actual time=0.014..0.271 rows=198 loops=1)
               Index Cond: (y < 100)
               Filter: (z < 100)
         ->  Bitmap Heap Scan on replan_test t2  (cost=13.44..17.46 rows=1 width=4)
 (actual time=34.278..34.295 rows=51 loops=198)
               Recheck Cond: ((y < 100) AND (t1.x = x))
               Filter: (z < 100)
               Heap Blocks: exact=298
               ->  BitmapAnd  (cost=13.44..13.44 rows=1 width=0) (actual
 time=34.268..34.268 rows=0 loops=198)
                     ->  Bitmap Index Scan on replan_test_y_idx  (cost=0.00..6.08
 rows=221 width=0) (actual time=0.016..0.016 rows=198 loops=198)
                           Index Cond: (y < 100)
                     ->  Bitmap Index Scan on replan_test_x_idx  (cost=0.00..7.11
 rows=357 width=0) (actual time=34.248..34.248 rows=505052 loops=198)
                           Index Cond: (x = t1.x)
   ->  Index Scan using replan_test_y_idx on replan_test t3  (cost=0.43..8.45 rows=1
 width=4) (actual time=0.004..0.005 rows=2 loops=10098)
         Index Cond: ((y = t1.y) AND (y < 100))
         Filter: (z < 100)
 Planning Time: 0.722 ms
 Execution Time: 6849.539 ms
(19 rows)
```

Output with replanning:

```
                                                                                QUERY PLAN

Chapter 78. Backup Manifest Format

The backup manifest generated by pg_basebackup is primarily intended to permit the backup to be verified using pg_verifybackup. However, it is also possible for other tools to read the backup manifest file and use the information contained therein for their own purposes. To that end, this chapter describes the format of the backup manifest file.

A backup manifest is a JSON document encoded as UTF-8. (Although in general JSON documents are required to be Unicode, Postgres Pro permits the `json` and `jsonb` data types to be used with any supported server encoding. There is no similar exception for backup manifests.) The JSON document is always an object; the keys that are present in this object are described in the next section.

78.1. Backup Manifest Top-level Object

The backup manifest JSON document contains the following keys.

`PostgreSQL-Backup-Manifest-Version`

The associated value is always the integer 1.

`Files`

The associated value is always a list of objects, each describing one file that is present in the backup. No entries are present in this list for the WAL files that are needed in order to use the backup, or for the backup manifest itself. The structure of each object in the list is described in Section 78.2.

`WAL-Ranges`

The associated value is always a list of objects, each describing a range of WAL records that must be readable from a particular timeline in order to make use of the backup. The structure of these objects is further described in Section 78.3.

`Manifest-Checksum`

This key is always present on the last line of the backup manifest file. The associated value is a SHA256 checksum of all the preceding lines. We use a fixed checksum method here to make it possible for clients to do incremental parsing of the manifest. While a SHA256 checksum is significantly more expensive than a CRC32C checksum, the manifest should normally be small enough that the extra computation won't matter very much.

78.2. Backup Manifest File Object

The object which describes a single file contains either a `Path` key or an `Encoded-Path` key. Normally, the `Path` key will be present. The associated string value is the path of the file relative to the root of the backup directory. Files located in a user-defined tablespace will have paths whose first two components are `pg_tblspc` and the OID of the tablespace. If the path is not a string that is legal in UTF-8, or if the user requests that encoded paths be used for all files, then the `Encoded-Path` key will be present instead. This stores the same data, but it is encoded as a string of hexadecimal digits. Each pair of hexadecimal digits in the string represents a single octet.

The following two keys are always present:

`Size`

The expected size of this file, as an integer.

`Last-Modified`

The last modification time of the file as reported by the server at the time of the backup. Unlike the other fields stored in the backup, this field is not used by pg_verifybackup. It is included only for informational purposes.

If the backup was taken with file checksums enabled, the following keys will be present:

`Checksum-Algorithm`

The checksum algorithm used to compute a checksum for this file. Currently, this will be the same for every file in the backup manifest, but this may change in future releases. At present, the supported checksum algorithms are `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`.

`Checksum`

The checksum computed for this file, stored as a series of hexadecimal characters, two for each byte of the checksum.

78.3. Backup Manifest WAL Range Object

The object which describes a WAL range always has three keys:

`Timeline`

The timeline for this range of WAL records, as an integer.

`Start-LSN`

The LSN at which replay must begin on the indicated timeline in order to make use of this backup. The LSN is stored in the format normally used by Postgres Pro; that is, it is a string consisting of two strings of hexadecimal characters, each with a length of between 1 and 8, separated by a slash.

`End-LSN`

The earliest LSN at which replay on the indicated timeline may end when making use of this backup. This is stored in the same format as `Start-LSN`.

Ordinarily, there will be only a single WAL range. However, if a backup is taken from a standby which switches timelines during the backup due to an upstream promotion, it is possible for multiple ranges to be present, each with a different timeline. There will never be multiple WAL ranges present for the same timeline.

Part VIII. Appendixes

Appendix A. Postgres Pro Error Codes

All messages emitted by the Postgres Pro server are assigned five-character error codes that follow the SQL standard's conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across Postgres Pro releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by Postgres Pro are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A.1 lists all the error codes defined in Postgres Pro Enterprise 16.9.1. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters `000`. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a `unique_violation` error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Table A.1. Postgres Pro Error Codes

Error Code	Condition Name
Class 00 — Successful Completion	
00000	successful_completion
Class 01 — Warning	
01000	warning
0100C	dynamic_result_sets_returned
01008	implicit_zero_bit_padding
01003	null_value_eliminated_in_set_function
01007	privilege_not_granted
01006	privilege_not_revoked
01004	string_data_right_truncation
01P01	deprecated_feature
Class 02 — No Data (this is also a warning class per the SQL standard)	
02000	no_data
02001	no_additional_dynamic_result_sets_returned
Class 03 — SQL Statement Not Yet Complete	
03000	sql_statement_not_yet_complete
Class 08 — Connection Exception	
08000	connection_exception

Error Code	Condition Name
08003	connection_does_not_exist
08006	connection_failure
08001	sqlclient_unable_to_establish_sqlconnection
08004	sqlserver_rejected_establishment_of_sqlconnection
08007	transaction_resolution_unknown
08P01	protocol_violation
Class 09 — Triggered Action Exception	
09000	triggered_action_exception
Class 0A — Feature Not Supported	
0A000	feature_not_supported
Class 0B — Invalid Transaction Initiation	
0B000	invalid_transaction_initiation
Class 0F — Locator Exception	
0F000	locator_exception
0F001	invalid_locator_specification
Class 0L — Invalid Grantor	
0L000	invalid_grantor
0LP01	invalid_grant_operation
Class 0P — Invalid Role Specification	
0P000	invalid_role_specification
Class 0Z — Diagnostics Exception	
0Z000	diagnostics_exception
0Z002	stacked_diagnostics_accessed_without_active_handler
Class 20 — Case Not Found	
20000	case_not_found
Class 21 — Cardinality Violation	
21000	cardinality_violation
Class 22 — Data Exception	
22000	data_exception
2202E	array_subscript_error
22021	character_not_in_repertoire
22008	datetime_field_overflow
22012	division_by_zero
22005	error_in_assignment
2200B	escape_character_conflict
22022	indicator_overflow
22015	interval_field_overflow
2201E	invalid_argument_for_logarithm
22014	invalid_argument_for_ntile_function

Error Code	Condition Name
22016	invalid_argument_for_nth_value_function
2201F	invalid_argument_for_power_function
2201G	invalid_argument_for_width_bucket_function
22018	invalid_character_value_for_cast
22007	invalid_datetime_format
22019	invalid_escape_character

Appendix B. Date/Time Support

Postgres Pro uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.

    a. If the numeric token contains a colon (`:`), this is a time string. Include all subsequent digits and colons.

    b. If the numeric token contains a dash (`-`), slash (`/`), or two or more dots (`.`), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., `America/New_York`).

    c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., `19990113` for January 13, 1999) or time (e.g., `141516` for 14:15:16).

    d. If the token starts with a plus (`+`) or minus (`-`), then it is either a numeric time zone or a special field.

2. If the token is an alphabetic string, match up with possible strings:

    a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in Section B.4.

    b. If not found, search an internal table to match the token as either a special string (e.g., `today`), day (e.g., `Thursday`), month (e.g., `January`), or noise word (e.g., `at`, `on`).

    c. If still not found, throw an error.

3. When the token is a number or number field:

    a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a "concatenated date" (e.g., `19990118` or `990118`). The interpretation is `YYYYMMDD` or `YYMMDD`.

    b. If the token is three digits and a year has already been read, then interpret as day of year.

    c. If four or six digits and a year has already been read, then interpret as a time (`HHMM` or `HHMMSS`).

    d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).

    e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.

4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

> **Tip**
>
> Gregorian years AD 1–99 can be entered by using 4 digits with leading zeros (e.g., `0099` is AD 99).

B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the TimeZone parameter is set to `America/New_York`, consider

```
=> SELECT '2018-03-11 02:30'::timestamptz;
      timestamptz
------------------------
 2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. Postgres Pro interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 01:30'::timestamptz;
      timestamptz
------------------------
 2018-11-04 01:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 1:30AM; there was 1:30AM EDT, and then an hour later after clocks jumped back from 2AM EDT to 1AM EST, there was 1:30AM EST. Again, Postgres Pro interprets the given time as if it were standard time (UTC-5). We can force the other interpretation by specifying daylight-savings time:

```
=> SELECT '2018-11-04 01:30 EDT'::timestamptz;
      timestamptz
------------------------
 2018-11-04 01:30:00-04
(1 row)
```

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

B.3. Date/Time Key Words

Table B.1 shows the tokens that are recognized as names of months.

Table B.1. Month Names

Month	Abbreviations
January	Jan
February	Feb
March	Mar
April	Apr
May	
June	Jun
July	Jul
August	Aug
September	Sep, Sept
October	Oct
November	Nov
December	Dec

Table B.2 shows the tokens that are recognized as names of days of the week.

Table B.2. Day of the Week Names

Day	Abbreviations
Sunday	Sun
Monday	Mon
Tuesday	Tue, Tues
Wednesday	Wed, Weds
Thursday	Thu, Thur, Thurs
Friday	Fri
Saturday	Sat

Table B.3 shows the tokens that serve various modifier purposes.

Table B.3. Date/Time Field Modifiers

Identifier	Description
`AM`	Time is before 12:00
`AT`	Ignored
`JULIAN, JD, J`	Next field is Julian Date
`ON`	Ignored
`PM`	Time is on or after 12:00
`T`	Next field is time

B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, Postgres Pro provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A *`zone_abbreviation`* is just the abbreviation being defined. An *`offset`* is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a *`time_zone_name`* can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

> **Tip**
>
> Using a simple integer *`offset`* is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc., containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

> **Note**
>
> If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into Postgres Pro. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

Caution

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

B.5. POSIX Time Zone Specifications

Postgres Pro can accept time zone specifications that are written according to the POSIX standard's rules for the `TZ` environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.

A POSIX time zone specification has the form

`STD offset [ DST [ dstoffset ] [ , rule ] ]`

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- *`STD`* is the zone abbreviation to be used for standard time.
- *`offset`* is the zone's standard-time offset from UTC.
- *`DST`* is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.
- *`dstoffset`* is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time *`offset`*, which is usually the right thing.
- *`rule`* defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as `EST`, or an arbitrary string surrounded by angle brackets, such as `<UTC-05>`. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in Section B.4.

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format *`hh`*[`:`*`mm`*[`:`*`ss`*]] optionally with a leading sign (`+` or `-`). The positive sign is used for zones *west* of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in Postgres Pro.) *`hh`* can have one or two digits; *`mm`* and *`ss`* (if used) must have two.

The daylight-savings transition *`rule`* has the format

`dstdate [ / dsttime ] , stddate [ / stdtime ]`

(As before, spaces should not be included in practice.) The *`dstdate`* and *`dsttime`* fields define when daylight-savings time starts, while *`stddate`* and *`stdtime`* define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

`n`

A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

`Jn`

In this form, *`n`* counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February

have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

`M`*m*`.`*n*`.`*d*

This form specifies a transition that always happens during the same month and on the same day of the week. *m* identifies the month, from 1 to 12. *n* specifies the *n*'th occurrence of the weekday identified by *d*. *n* is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). *d* is a number between 0 and 6, with 0 indicating Sunday. For example, `M3.2.0` means “the second Sunday in March”.

> **Note**
>
> The `M` format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to `02:00:00`.

If a daylight-savings abbreviation is given but the transition *rule* field is omitted, the fallback behavior is to use the rule `M3.2.0,M11.1.0`, which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both transitions occurring at 2AM prevailing time). Note that this rule does not give correct USA transition dates for years before 2007.

As an example, `CET-1CEST,M3.5.0,M10.5.0/3` describes current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation `CET` and is one hour ahead (east) of UTC; daylight savings time has the abbreviation `CEST` and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names `EST5EDT`, `CST6CDT`, `MST7MDT`, and `PST8PDT` look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, `SET TIMEZONE TO FOOBAR0` will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. Postgres Pro follows the SQL standard's lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as 365 1/4 days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as

365 + 97 / 400 days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation 365+97/400 is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.
However, every year divisible by 100 is not a leap year.
However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the `cal` program produce the following:

```
$ cal 9 1752
   September 1752
 S  M Tu  W Th  F  S
       1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, Postgres Pro does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

B.7. Julian Dates

The *Julian Date* system is a method for numbering days. It is unrelated to the Julian calendar, though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540–1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484–1558).

In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although Postgres Pro supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. Postgres Pro treats a Julian Date as running from local midnight to local midnight, the same as a normal date.

This definition does, however, provide a way to obtain the astronomical definition when you need it: do the arithmetic in time zone `UTC+12`. For example,

```
=> SELECT extract(julian from '2021-06-23 7:00:00-04'::timestamptz at time zone 'UTC
+12');
           extract
-----------------------------
 2459388.9583333333333333333
(1 row)
=> SELECT extract(julian from '2021-06-23 8:00:00-04'::timestamptz at time zone 'UTC
+12');
               extract
--------------------------------------
 2459389.0000000000000000000000000000
(1 row)
=> SELECT extract(julian from date '2021-06-23');
 extract
---------
 2459389
(1 row)
```

Appendix C. SQL Key Words

Table C.1 lists all tokens that are key words in the SQL standard and in Postgres Pro Enterprise 16.9.1. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the Postgres Pro parser, life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser, but are considered ordinary identifiers. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in Postgres Pro, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In Table C.1 in the column for Postgres Pro we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as a column label. A blank entry in this column means that the word is treated as an ordinary identifier by Postgres Pro.

Furthermore, while most key words can be used as “bare” column labels without writing `AS` before them (as described in Section 7.3.2), there are a few that require a leading `AS` to avoid ambiguity. These are marked in the table as “requires `AS`”.

As a general rule, if you get spurious parser errors for commands that use any of the listed key words as an identifier, you should try quoting the identifier to see if the problem goes away.

It is important to understand before studying Table C.1 that the fact that a key word is not reserved in Postgres Pro does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Table C.1. SQL Key Words

Key Word	PostgreSQL	SQL:2023	SQL:2016	SQL-92

Appendix D. SQL Conformance

This section attempts to outline to what extent Postgres Pro conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2023. The 2023 version is referred to as ISO/IEC 9075:2023, or simply as SQL:2023. The versions prior to that were SQL:2016, SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. Postgres Pro development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard is split into a number of parts, each also known by a shorthand name:

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)
- ISO/IEC 9075-16 Property Graph Queries (SQL/PGQ)

Note that some part numbers are not (or no longer) used.

The Postgres Pro core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, 15, and 16 for Postgres Pro.

Postgres Pro supports most of the major features of SQL:2023. Out of 177 mandatory features required for full Core conformance, Postgres Pro conforms to at least 170. In addition, there is a long list of

supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2023.

In the following two sections, we provide a list of those features that Postgres Pro supports, followed by a list of the features defined in SQL:2023 which are not yet supported in Postgres Pro. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

> **Note**
>
> Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.1. Supported Features

Identifier	Core?	Description	Comment
B012		Embedded C	
B021		Direct SQL	
B128		Routine language SQL	
E011	Core	Numeric data types	
E011-01	Core	INTEGER and SMALLINT data types	
E011-02	Core	REAL, DOUBLE PRECISION, and FLOAT data types	
E011-03	Core	DECIMAL and NUMERIC data types	
E011-04	Core	Arithmetic operators	
E011-05	Core	Numeric comparison	
E011-06	Core	Implicit casting among the numeric data types	
E021	Core	Character data types	
E021-01	Core	CHARACTER data type	
E021-02	Core	CHARACTER VARYING data type	
E021-03	Core	Character literals	
E021-04	Core	CHARACTER_LENGTH function	trims trailing spaces from CHARACTER values before counting
E021-05	Core	OCTET_LENGTH function	
E021-06	Core	SUBSTRING function	
E021-07	Core	Character concatenation	
E021-08	Core	UPPER and LOWER functions	
E021-09	Core	TRIM function	
E021-10	Core	Implicit casting among the character string types	
E021-11	Core	POSITION function	
E021-12	Core	Character comparison	
E031	Core	Identifiers	
E031-01	Core	Delimited identifiers	
E031-02	Core	Lower case identifiers	
E031-03	Core	Trailing underscore	

Identifier	Core?	Description	Comment
E051	Core	Basic query specification	
E051-01	Core	SELECT DISTINCT	
E051-02	Core	GROUP BY clause	
E051-04	Core	GROUP BY can contain columns not in <select list>	
E051-05	Core	Select list items can be renamed	
E051-06	Core	HAVING clause	
E051-07	Core	Qualified * in select list	
E051-08	Core	Correlation names in the FROM clause	
E051-09	Core	Rename columns in the FROM clause	
E061	Core	Basic predicates and search conditions	
E061-01	Core	Comparison predicate	
E061-02	Core	BETWEEN predicate	
E061-03	Core	IN predicate with list of values	
E061-04	Core	LIKE predicate	
E061-05	Core	LIKE predicate ESCAPE clause	
E061-06	Core	NULL predicate	
E061-07	Core	Quantified comparison predicate	
E061-08	Core	EXISTS predicate	
E061-09	Core	Subqueries in comparison predicate	
E061-11	Core	Subqueries in IN predicate	
E061-12	Core	Subqueries in quantified comparison predicate	
E061-13	Core	Correlated subqueries	
E061-14	Core	Search condition	
E071	Core	Basic query expressions	
E071-01	Core	UNION DISTINCT table operator	
E071-02	Core	UNION ALL table operator	
E071-03	Core	EXCEPT DISTINCT table operator	
E071-05	Core	Columns combined via table operators need not have exactly the same data type	
E071-06	Core	Table operators in subqueries	
E081	Core	Basic Privileges	
E081-01	Core	SELECT privilege	
E081-02	Core	DELETE privilege	
E081-03	Core	INSERT privilege at the table level	
E081-04	Core	UPDATE privilege at the table level	
E081-05	Core	UPDATE privilege at the column level	
E081-06	Core	REFERENCES privilege at the table level	
E081-07	Core	REFERENCES privilege at the column level	
E081-08	Core	WITH GRANT OPTION	
E081-09	Core	USAGE privilege	
E081-10	Core	EXECUTE privilege	

Identifier	Core?	Description	Comment
E091	Core	Set functions	
E091-01	Core	AVG	
E091-02	Core	COUNT	
E091-03	Core	MAX	
E091-04	Core	MIN	
E091-05	Core	SUM	
E091-06	Core	ALL quantifier	
E091-07	Core	DISTINCT quantifier	
E101	Core	Basic data manipulation	
E101-01	Core	INSERT statement	
E101-03	Core	Searched UPDATE statement	
E101-04	Core	Searched DELETE statement	
E111	Core	Single row SELECT statement	
E121	Core	Basic cursor support	
E121-01	Core	DECLARE CURSOR	
E121-02	Core	ORDER BY columns need not be in select list	
E121-03	Core	Value expressions in ORDER BY clause	
E121-04	Core	OPEN statement	
E121-06	Core	Positioned UPDATE statement	
E121-07	Core	Positioned DELETE statement	
E121-08	Core	CLOSE statement	
E121-10	Core	FETCH statement implicit NEXT	
E121-17	Core	WITH HOLD cursors	
E131	Core	Null value support (nulls in lieu of values)	
E141	Core	Basic integrity constraints	
E141-01	Core	NOT NULL constraints	
E141-02	Core	UNIQUE constraints of NOT NULL columns	
E141-03	Core	PRIMARY KEY constraints	
E141-04	Core	Basic FOREIGN KEY constraint with the NO ACTION default for both referential delete action and referential update action	
E141-06	Core	CHECK constraints	
E141-07	Core	Column defaults	
E141-08	Core	NOT NULL inferred on PRIMARY KEY	
E141-10	Core	Names in a foreign key can be specified in any order	
E151	Core	Transaction support	
E151-01	Core	COMMIT statement	
E151-02	Core	ROLLBACK statement	
E152	Core	Basic SET TRANSACTION statement	
E152-01	Core	SET TRANSACTION statement: ISOLATION LEVEL SERIALIZABLE clause	

Identifier	Core?	Description	Comment
E152-02	Core	SET TRANSACTION statement: READ ONLY and READ WRITE clauses	
E153	Core	Updatable queries with subqueries	
E161	Core	SQL comments using leading double minus	
E171	Core	SQLSTATE support	
E182	Core	Host language binding	
F021	Core	Basic information schema	
F021-01	Core	COLUMNS view	
F021-02	Core	TABLES view	
F021-03	Core	VIEWS view	
F021-04	Core	TABLE_CONSTRAINTS view	
F021-05	Core	REFERENTIAL_CONSTRAINTS view	
F021-06	Core	CHECK_CONSTRAINTS view	
F031	Core	Basic schema manipulation	
F031-01	Core	CREATE TABLE statement to create persistent base tables	
F031-02	Core	CREATE VIEW statement	
F031-03	Core	GRANT statement	
F031-04	Core	ALTER TABLE statement: ADD COLUMN clause	
F031-13	Core	DROP TABLE statement: RESTRICT clause	
F031-16	Core	DROP VIEW statement: RESTRICT clause	
F031-19	Core	REVOKE statement: RESTRICT clause	
F032		CASCADE drop behavior	
F033		ALTER TABLE statement: DROP COLUMN clause	
F034		Extended REVOKE statement	
F035		REVOKE with CASCADE	
F036		REVOKE statement performed by non-owner	
F037		REVOKE statement: GRANT OPTION FOR clause	
F038		REVOKE of a WITH GRANT OPTION privilege	
F041	Core	Basic joined table	
F041-01	Core	Inner join (but not necessarily the INNER keyword)	
F041-02	Core	INNER keyword	
F041-03	Core	LEFT OUTER JOIN	
F041-04	Core	RIGHT OUTER JOIN	
F041-05	Core	Outer joins can be nested	
F041-07	Core	The inner table in a left or right outer join can also be used in an inner join	
F041-08	Core	All comparison operators are supported (rather than just =)	
F051	Core	Basic date and time	
F051-01	Core	DATE data type (including support of DATE literal)	

Identifier	Core?	Description	Comment
F051-02	Core	TIME data type (including support of TIME literal) with fractional seconds precision of at least 0	
F051-03	Core	TIMESTAMP data type (including support of TIMESTAMP literal) with fractional seconds precision of at least 0 and 6	
F051-04	Core	Comparison predicate on DATE, TIME, and TIMESTAMP data types	
F051-05	Core	Explicit CAST between datetime types and character string types	
F051-06	Core	CURRENT_DATE	
F051-07	Core	LOCALTIME	
F051-08	Core	LOCALTIMESTAMP	
F052		Intervals and datetime arithmetic	
F053		OVERLAPS predicate	
F081	Core	UNION and EXCEPT in views	
F111		Isolation levels other than SERIALIZABLE	
F112		Isolation level READ UNCOMMITTED	
F113		Isolation level READ COMMITTED	
F114		Isolation level REPEATABLE READ	
F131	Core	Grouped operations	
F131-01	Core	WHERE, GROUP BY, and HAVING clauses supported in queries with grouped views	
F131-02	Core	Multiple tables supported in queries with grouped views	
F131-03	Core	Set functions supported in queries with grouped views	
F131-04	Core	Subqueries with GROUP BY and HAVING clauses and grouped views	
F131-05	Core	Single row SELECT with GROUP BY and HAVING clauses and grouped views	
F171		Multiple schemas per user	
F181	Core	Multiple module support	
F191		Referential delete actions	
F200		TRUNCATE TABLE statement	
F201	Core	CAST function	
F202		TRUNCATE TABLE: identity column restart option	
F221	Core	Explicit defaults	
F222		INSERT statement: DEFAULT VALUES clause	
F231		Privilege tables	
F251		Domain support	
F261	Core	CASE expression	
F261-01	Core	Simple CASE	
F261-02	Core	Searched CASE	
F261-03	Core	NULLIF	
F261-04	Core	COALESCE	

Identifier	Core?	Description	Comment
F262		Extended CASE expression	
F271		Compound character literals	
F281		LIKE enhancements	
F292		UNIQUE null treatment	
F302		INTERSECT table operator	
F303		INTERSECT DISTINCT table operator	
F304		EXCEPT ALL table operator	
F305		INTERSECT ALL table operator	
F311	Core	Schema definition statement	
F311-01	Core	CREATE SCHEMA

T851		SQL/JSON: optional keywords for default syntax	
T879		JSON in equality operations	with jsonb
T880		JSON in grouping operations	with jsonb
X010		XML type	
X011		Arrays of XML type	
X014		Attributes of XML type	
X016		Persistent XML values	
X020		XMLConcat	
X031		XMLElement	
X032		XMLForest	
X034		XMLAgg	
X035		XMLAgg: ORDER BY option	
X036		XMLComment	
X037		XMLPI	
X040		Basic table mapping	
X041		Basic table mapping: null absent	
X042		Basic table mapping: null as nil	
X043		Basic table mapping: table as forest	
X044		Basic table mapping: table as element	
X045		Basic table mapping: with target namespace	

Identifier	Core?	Description	Comment
X046		Basic table mapping: data mapping	
X047		Basic table mapping: metadata mapping	
X048		Basic table mapping: base64 encoding of binary strings	
X049		Basic table mapping: hex encoding of binary strings	
X050		Advanced table mapping	
X051		Advanced table mapping: null absent	
X052		Advanced table mapping: null as nil	
X053		Advanced table mapping: table as forest	
X054		Advanced table mapping: table as element	
X055		Advanced table mapping: with target namespace	
X056		Advanced table mapping: data mapping	
X057		Advanced table mapping: metadata mapping	
X058		Advanced table mapping: base64 encoding of binary strings	
X059		Advanced table mapping: hex encoding of binary strings	
X060		XMLParse: character string input and CONTENT option	
X061		XMLParse: character string input and DOCUMENT option	
X069		XMLSerialize: INDENT	
X070		XMLSerialize: character string serialization and CONTENT option	
X071		XMLSerialize: character string serialization and DOCUMENT option	
X072		XMLSerialize: character string serialization	
X090		XML document predicate	
X120		XML parameters in SQL routines	
X121		XML parameters in external routines	
X221		XML passing mechanism BY VALUE	
X301		XMLTable: derived column list option	
X302		XMLTable: ordinality column option	
X303		XMLTable: column default option	
X304		XMLTable: passing a context item	must be XML DOCUMENT
X400		Name and identifier mapping	
X410		Alter column data type: XML type	

D.2. Unsupported Features

The following features defined in SQL:2023 are not implemented in this release of Postgres Pro. In a few cases, equivalent functionality is available.

Identifier	Core?	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	

Identifier	Core?	Description	Comment
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B030		Enhanced dynamic SQL	
B031		Basic dynamic SQL	
B032		Extended dynamic SQL	
B033		Untyped SQL-invoked function arguments	
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B036		Describe input statement	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	
B124		Routine language Fortran	
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B200		Polymorphic table functions	
B201		More than one PTF generic table parameter	
B202		PTF copartitioning	
B203		More than one copartition specification	
B204		PRUNE WHEN EMPTY	
B205		Pass-through columns	
B206		PTF descriptor parameters	
B207		Cross products of partitionings	
B208		PTF component procedure interface	
B209		PTF extended names	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support

X305		XMLTable: initializing an XQuery variable	

D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. Postgres Pro's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type `XML(SEQUENCE)` to hold arbitrary pieces of XML content, Postgres Pro provides the single `xml` type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- Postgres Pro provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

This section presents some of the resulting differences you may encounter.

D.3.1. Queries Are Restricted to XPath 1.0

The Postgres Pro-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. Postgres Pro also provides XPath-only variants of the standard functions `XMLEXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, Postgres Pro relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the Postgres Pro-specific functions.

D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the `sequence`, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

> **Note**
>
> The libxml2 library does seem to always return node-sets to Postgres Pro with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if ( hat ) then hat/@size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two `NaN`s. In contrast, `=` and `!=` do compare the strings as strings.
- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute, but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.
- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any Postgres Pro XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of *function library changes* and *language changes* applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

D.3.1.3. Mappings between SQL and XML Data Types and Values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When Postgres Pro maps SQL data values to XML (as in `xmlelement`), or XML to SQL (as in the output columns of `xmltable`), except for a few cases treated specially, Postgres Pro simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and

conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in Section 9.8) explicitly to produce the standard mappings.

D.3.2. Incidental Limits of the Implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in Postgres Pro.

D.3.2.1. Only `BY VALUE` Passing Mechanism Is Supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if *x* is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON EMPTY);
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON EMPTY);
```

Postgres Pro will accept `BY VALUE` or `BY REF` in an `XMLEXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

D.3.2.2. Cannot Pass Named Parameters to Queries

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

D.3.2.3. No `XML(SEQUENCE)` Type

The Postgres Pro `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that Postgres Pro can supply as an XPath context item.

Appendix E. Release Notes

The release notes contain the significant changes in each Postgres Pro Enterprise release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

E.1. Postgres Pro Enterprise 16.9.1

Release Date: 2025-06-11

E.1.1. Overview

This release is based on PostgreSQL 16.9 and Postgres Pro Enterprise 16.8.3. All changes inherited from PostgreSQL 16.9 are listed in PostgreSQL 16.9 Release Notes. As compared with Postgres Pro Enterprise 16.8.3, this version provides the following changes:

- Added the experimental feature that allows temporary tables in parallel queries and can be enabled using the new enable_parallel_temptables configuration parameter. This feature cannot be used in production for now. Also, added the new write_page_cost configuration parameter that allows estimating the cost of flushing temporary table pages to disk. It will only work if `enable_parallel_temptables` is enabled.
- Added the new planner_upper_limit_estimation configuration parameter that enables the query planner to overestimate the expected number of rows in statements that contain a comparison to an unknown constant.
- Added the experimental feature that allows using an in-memory system catalog for temporary tables, and can be enabled using the new enable_temp_memory_catalog configuration parameter. This feature cannot be used in production for now.
- Added a possibility for the autovacuum daemon to process indexes of a table in a parallel mode. The parallel_autovacuum_workers storage parameter of a table controls whether it should be processed in parallel and defines the number of additional parallel autovacuum workers that can be launched for table processing. The number of autovacuum workers per cluster that can be used for parallel table processing is limited by the autovacuum_max_workers configuration parameter. Parallel autovacuum is currently in an experimental phase and is intended for testing purposes only. Do not deploy it in production environments.
- Implemented the following enhancements and bug fixes for real-time query replanning:
  - Added a possibility to trigger the real-time query replanning for a query that is currently run in the specified session. The replanning request is sent by the `replan_signal` function.
  - Hid the confusing “early terminated” notice in `EXPLAIN VERBOSE` unless `replan_enable` was on and query replanning was active.
  - Fixed an issue with real-time query replanning failing to optimize queries with subqueries.
- Added the enable_alternative_sorting_cost_model configuration parameter, which allows you to enable or disable the query planner's use of alternative model for estimating the cost of tuple sorting.
- Added the enable_any_to_lateral_transformation configuration parameter that allows enabling or disabling transformation of `ANY` subqueries into `LATERAL` joins.
- Implemented performance optimization when working with table metadata, which allows obtaining information about attributes using the system cache instead of direct reading from the system catalog.
- Introduced the following changes to the implementation of crash_info:
  - Added handling of `SIGILL` signals to `crash_info` processing.

    - Added details, like process start time and query text at planning, to `crash_info` output files.
    - Fixed incorrect function names in the first 2-3 lines of `crash_info` backtrace stacks.
    - Fixed possible data truncation at the end of SQL query dump files. Previously, a buffer overflow during SQL query dumping could result in incomplete writes, causing truncated data at the end of files produced by `crash_info`.
    - Fixed handling of crash information signals (sent using the kill command) by backends. Previously, the first signal would flush `crash_info` information to the log, but the process would continue running without producing a core dump, even if configured, and only the second signal would terminate the backend and generate the core dump as expected.
- Restricted superuser actions with temporary relations of other sessions. Superusers can now only use the `DROP TABLE` command with such relations. If the skip_temp_rel_lock configuration parameter is set to `on`, even dropping such relations is not allowed.
- Fixed the following issues for CFS:
    - Fixed compatibility of CFS with the `ALTER TABLESPACE ... SET/RESET` commands.
    - Fixed an issue with memory allocation within a critical section in the implementation of `VACUUM ANALYZE` for compressed tables.
- Fixed the following bugs related to autonomous transactions:
    - Fixed a segmentation fault, which could occur when using postgres_fdw with autonomous transactions.
    - Fixed loss of temporary tables from parent transaction on autonomous transaction rollback.
    - Fixed an issue with empty `xact_start` columns in the `pg_stat_activity` view for backends executing autonomous transactions.
- Fixed an issue with missing statistics about vacuuming when multiple index vacuum workers are used.
- Fixed misuse of spinlocks in the automatic page repair worker.
- Added the daterange_inclusive extension, which allows you to include the upper bound of a time range in output.
- Added the pg_failover_slots extension as a separate pre-built package. pg_failover_slots is designed for automatic creation and synchronization of logical replication slots on physical replicas.
- Added the *pg_probackup3* solution for backup and recovery of Postgres Pro database clusters. Refer to the pg_probackup3 *release notes* for more details.
- Added the pgpro_bindump module to manage backup and restore operations. This module implements specialized replication commands for an extended replication protocol, has its own format for archiving files, and does not require SSH connection. It is designed specifically for use with the *pg_probackup3* utility.
- Added the pgpro_datactl utility to manage Postgres Pro data files, which includes a module for unpacking and analyzing CFS files.
- Added the pgpro_result_cache extension to save query results for reuse.
- Added the new pgpro_tune utility for automatic tuning of Postgres Pro configuration parameters.
- Upgraded the BiHA solution to version 1.5 to provide the following features, optimizations, and bug fixes:
    - Added the biha.set_sync_standbys function that allows configuring quorum-based synchronous replication on the existing asynchronous BiHA cluster. You can also use the function to change the number of quorum-based synchronous standbys. For more information, see Configuring Quorum-Based Synchronous Replication on the Existing BiHA Cluster.

- Improved the process of the `biha_replication_user` password verification during BiHA cluster initialization. If you have preliminary specified the password in the password file, bihactl now gets the password automatically. If you have not specified the password in the password file, you are now prompted to enter the password twice to avoid misspelling.
- Changed the connection database from `postgres` to `biha_db` for the automatic rewind functionality. This helps to avoid automatic rewind errors in cases when the connection string for the `postgres` database is not present in the password file.
- Added the `LEADER_CHANGE_STARTED` callback type that is called on all nodes when the leader is not available and the quorum is ready to start elections or when you set the leader by the biha.set_leader function. You can use this callback to fence the old leader. For more information about the new callback, see Callback Types.
- Added the --referee-with-postgres-db option of the `bihactl add` command that allows to copy the `postgres` database to the referee node. For more information, see The postgres Database on the Referee.
- Changed the behavior of nodes in the `NODE_ERROR` state during elections. Such nodes can no longer participate in voting.
- Expanded the list of cluster parameters returned by the biha.config function. The function now also returns the `mode` column displaying the operation mode of the node: `regular`, `referee`, or `referee_with_wal`.
- Fixed an issue with multiple “waiting for WAL to become available at...” log messages on the referee node in the `referee` mode.
- Fixed a bug that caused a segmentation fault when calling `biha.set_*` functions in a single-node (leader only) BiHA cluster.
- Fixed an issue of decreasing the max_wal_senders parameter in a single-node (leader only) BiHA cluster. For more information about decreasing `max_wal_senders` and some other Postgres Pro configuration parameters, see Decreasing Postgres Pro Parameter Values.
- Fixed a bug where nodes attempted to check the biha.sync_standbys_min value when updating configuration of the asynchronous BiHA cluster.
- Fixed a bug that allowed to set an empty password for `biha_replication_user` when executing the init command.
- Fixed a bug where the old leader in the `CSTATE_FORMING` state could ignore progressing elections and start as the leader together with the new leader. Now, the old leader does not start as the leader if it detects a node in the `CANDIDATE` state.
- Fixed a bug that caused unexpected cluster behavior when the biha.sync_standbys_min value was set outside the valid range by the biha.set_sync_standbys_min function. BiHA now does not allow to modify the `biha.sync_standbys_min` parameter if the new value is higher than the number of quorum-based synchronous nodes of the synchronous_standby_names parameter.

- Upgraded citus to version 12.1.7.1.
- Upgraded dbms_lob to version 1.3 to fix incorrect handling of the *`amount`* in `write`. If *`buffer`* is longer, it writes exactly *`amount`* bytes (for BLOB) or characters (for CLOB).
- Upgraded the pg_hint_plan module to ignore hints of the new pgpro_result_cache extension.
- Added a new `PGPRO_TUNE` environment variable to initdb, which specifies whether to use pgpro_tune without modifying command-line options directly.
- Upgraded multimaster to version 1.3.0, which provides the following enhancements and bug fixes:
  - Improved the way nodes delete old synchronization points. Previously, every node deleted only a part of the synchronization point table and replicated changes to other nodes. This could cause synchronization issues and inability to delete old synchronization points. Now, every node deletes all synchronization points and does not replicate changes to other nodes.

    - Fixed potential node hanging during catchup when attempting to process aborted DDL transactions in a cluster of three or more nodes.
- Upgraded oracle_fdw to increase line size for EXPLAIN output as some Oracle catalog queries have long filter conditions. The line size was increased to the value of 3000.
- Fixed an issue with updating pageinspect. In rare cases, depending on the sequence of previous updates, upgrading the database cluster and then attempting to update the pageinspect extension using `ALTER EXTENSION pageinspect UPDATE TO` could result in an error. To avoid such issues, it is strongly recommended to drop and recreate the extension using `DROP EXTENSION` followed by `CREATE EXTENSION` after upgrading the cluster. Since pageinspect does not create dependent objects, this approach is safe.
- Upgraded pg_proaudit to provide the following enhancements and bug fixes:
    - Added new object types: `CATALOG RELATION` and `CATALOG FUNCTION`.
    - Added new event fields: UUID, XID, and VXID. Now it is possible to identify an event by its UUID and transaction IDs (if applicable).
    - The behavior of the `pg_proaudit.log_catalog_access` configuration parameter was corrected to reflect the new logic of logging for system catalog objects.
    - Changed the logic of handling disconnection events. Now these events are associated with the corresponding authentication events, so the disconnection events will be logged even in the case when the rule is removed after authentication, but before disconnect.
    - Fixed an issue where the `DISCONNECT` event type was not logged for a user who was a member of the role that was set in the logging rule.
    - Fixed the bug that caused a log entry to be written to an incorrect log file when log file rotation was configured.
    - Fixed an issue with pg_proaudit failing to log schema creation events.
    - Corrected the behavior of the `logger` process when deleting a role from a parallel session configured by the rule.
- Upgraded pg_probackup to version 2.8.9 Enterprise, which provides the following new features, optimizations, and bug fixes:
    - Added the `maintain` command to resolve issues that can occur during a forced backup termination.
    - Added the `--lock-lifetime` option that sets the timeout for locks. This option is useful for computational environments with a slow network.
    - Stabilized retaining the initial permissions for directories when running the `init` command.
    - Stabilized the `checkdb` command on a remote host.
    - Improved the stability of the point-in-time recovery (PITR) with validation.
    - Fixed the “SignatureDoesNotMatch” error that could occur when connecting to the VK Cloud S3 storage.
    - Fixed an incorrect behavior that could occur when launching the wait for a WAL streaming thread in the ARCHIVE WAL delivery mode.
- Upgraded pgpro_bfile to version 1.3 to add the new `bfile_md5()` function that calculates a 16-byte MD5 hash for the specified `bfile` object.
- Upgraded pgpro_multiplan to version 1.2, which provides the following enhancements and bug fixes:
    - Added the `set_aqe_trigger()` function that allows you to override global trigger values of real-time query replanning for individual queries. All individual trigger values are stored in the

new `aqe_triggers` view. The new pgpro_multiplan.aqe_max_items parameter specifies the maximum number of items in this view.

- Added the new pgpro_multiplan.aqe_collect_stats parameter that enables pgpro_multiplan to collect statistics for all statements considered feasible for real-time query replanning reoptimization. All statistics values are stored in the new `aqe_stats` view. The new pgpro_multiplan.aqe_max_stats parameter specifies the maximum number of collected statistics values.
- Added the pgpro_multiplan.aqe_plans_auto_approve parameter that enables pgpro_multiplan to add plans produced by real-time query replanning to the list of allowed plans automatically.
- Implemented the ability to back up frozen plans and then restore them into the current database using the `pgpro_multiplan_restore()` function. You can now transfer frozen plans between databases or even server instances.
- Fixed a `PANIC`-level failure in pgpro_multiplan, which could occur if the standby had a different pgpro_multiplan version than the primary.
- Fixed an issue, which could cause errors like “unrecognized node type” when working with stored procedures and functions.
- Fixed empty hint string generation in pgpro_multiplan, which caused pg_hint_plan to report a syntax error.

- Upgraded pgpro_pwr to version 4.9, which mainly provides optimizations and bug fixes. Notable changes are as follows:
  - Added support for pgpro_stats 1.9.
  - Added a possibility to define the mode of collecting relation sizes globally through the `pgpro_pwr.relsize_collect_mode` extension parameter or for a server through the `set_server_size_sampling` function parameter.
  - Enabled fine-tuning the server statistics collection by calling the `set_server_setting` function. It allows you to define which statistics should be collected.
  - Added a preview of storage parameters for tables and indexes in the “Schema object statistics” report section.
- Upgraded pgpro_rp to version 1.3 to prevent related dump/restore failures. Previously, creating the pgpro_rp extension before restoring a dump could lead to a unique constraint violation during restoration of pgpro_rp.
- Upgraded pgpro_scheduler to version 2.11.2 to fix an issue where repeated jobs could be executed at additional time if days of the week were set using the `crontab` format. pgpro_scheduler now checks all job time settings and runs jobs at the specified time.
- Upgraded pgpro_sfile to version 1.5, which provides the following bug fixes and improvements:
  - Added the variant of the `sf_find` function that searches an `sfile` object by an ID of the `bigint` type and to implement the type cast `bigint::sfile`.
  - Fixed an issue in pgpro_sfile, which could cause errors like “tuple concurrently updated” during `DELETE` or `TRUNCATE` operations.
- Upgraded pgpro_stats to version 1.9, which provides the following bug fixes and improvements:
  - Enhanced session tracing to provide more information. Specifically, the new `time_info` filter attribute controls inclusion of additional information in the session-tracing output, and the `pgpro_stats.trace_query_text_size` configuration parameter can limit the size of the query in the session-tracing output.
  - Aligned the names of the `explain_*` filter attributes of the session tracer with the names of session-tracing configuration parameters.
  - Changed the format of the statistics dump file and the corresponding save/load routines.

  - Implemented turning off the session tracer functionality when no session-tracing filters are specified.
  - Prohibited inclusion of both pgpro_stats and pg_stat_statements in the list of `shared_preload_libraries`. If both are included, the database server will not start.
- Upgraded the pg_wait_sampling extension to provide the following bug fixes:
  - Fixed an issue where GUC variables could be overridden when using parallel workers.
  - Fixed an issue with malformed samples caused by a race condition when `pg_wait_sampling.sample_cpu` is disabled.
- Fixed an issue with sr_plan failing to register queries involving the `INTERVAL 'const'` notation.
- Removed the `--tune` option from `pg-setup`. Use the new pgpro_tune utility instead.
- Deprecated the experimental vops extension.

E.1.2. Migration to Version 16.9.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

> **Important**
>
> To upgrade your BiHA cluster from Postgres Pro Enterprise 16.8 or earlier to Postgres Pro Enterprise 16.9, see migration instructions for BiHA.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

When upgrading your high-availability cluster from Postgres Pro Enterprise versions 16.3.x or lower, first disable automatic failover if it was enabled and upgrade all the standby servers, then upgrade the primary server, promote a standby, and restart the former primary (possibly with pg_rewind).

If you take backups using pg_probackup and you have previously upgraded it to version 2.8.0 Enterprise or 2.8.1 Enterprise, make sure to upgrade it to version 2.8.2 Enterprise or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.2. Postgres Pro Enterprise 16.8.3

Release Date: 2025-05-07

E.2.1. Overview

This release is based on Postgres Pro Enterprise 16.8.2. As compared with Postgres Pro Enterprise 16.8.2, this version provides the following change:

- Changed lock logic to reduce CPU consumption significantly in case of startup recovery on physical replicas used as a source for logical replication with many downstreams. Walsenders no longer slow down WAL application as a more efficient synchronization primitive has replaced the previously used spinlock.

E.2.2. Migration to Version 16.8.3

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.3. Postgres Pro Enterprise 16.8.2

Release Date: 2025-04-11

E.3.1. Overview

This release is based on Postgres Pro Enterprise 16.8.1. As compared with Postgres Pro Enterprise 16.8.1, this version provides the following changes:

- Fixed high CPU consumption on a standby instance with enabled cascading logical replication. Now wake-ups of walsender processes are sent after applying a group of WAL records rather than each individual record in case of high stream of changes from the upstream instance.
- Fixed an issue when the checkpointer process could get stuck, repeatedly throwing “invalid memory alloc request size” errors. This could occur when using a huge `shared_buffers` setting, causing memory allocation requests to exceed the allowed limit.
- Fixed a segmentation fault, which could occur when using postgres_fdw with autonomous transactions.
- Upgraded oracle_fdw to fix a crash with column options on non-existing columns. If the Oracle table has fewer columns than the Postgres Pro and one of these extra columns has a column option set, oracle_fdw would write past the end of an array, leading to memory corruption and crashes. Now options for such columns are ignored.

E.3.2. Migration to Version 16.8.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.4. Postgres Pro Enterprise 16.8.1

Release Date: 2025-03-10

E.4.1. Overview

This release is based on PostgreSQL 16.8 and Postgres Pro Enterprise 16.6.1. All changes inherited from PostgreSQL 16.8 are listed in PostgreSQL 16.8 Release Notes. As compared with Postgres Pro Enterprise 16.6.1, this version also provides the following changes:

- Added details, like current working directory, the `PGDATA` directory, etc., to `crash_info` output files.
- Added the increased security requirements for the CREATE PROFILE command. Now the `PASSWORD_REQUIRE_COMPLEX` parameter requires characters from three different groups. Also, all characters of languages without case distinction (Hindi, Chinese, etc.) in the UTF-8 encoding are considered lowercase.
- Added the skip_temp_rel_lock configuration parameter, which allows you to skip locking for temporary relations.

- Improved real-time query replanning. Now replan triggers are disabled for future reoptimization, when one of the following conditions is met: no new information was gathered during execution, the newly generated plan matches a plan that was already tried, or the maximum number of reruns, set by the replan_max_attempts configuration parameter, was reached.
- Restricted citus operation with enable_self_join_removal set to `on`. Previously, queries to distributed tables of the extension could return incorrect results. Now, query planning results in an error if the optimizer decides to make the query distributed.
- Implemented the following enhancements and bug fixes for CFS:
  - Changed the default value for the cfs_gc_threshold configuration parameter from 50 to 30 percent.
  - Fixed an issue with CFS garbage collector being blocked by the backup process. If backup took ran too long, this could lead to write locks, preventing writes to compressed tablespaces. Now both processes lock only specific data files briefly, avoiding mutual blocking.
  - Fixed an issue with missing compression settings for tablespaces on standby servers by adding a new WAL record type. Previously, standby servers did not receive such compression settings because `ALTER TABLESPACE ... SET (compression=true)` was not logged in WAL.
  - Fixed the `cfs_start_gc` function to reject invalid values of the `n_workers` argument.
- Fixed an issue with upgrading Postgres Pro Standard to Postgres Pro Enterprise using pg_upgrade, which could fail if the old cluster had an epoch greater than 1 with an error like “could not open file”.
- Fixed an issue with handling `*.cfm.bck` files by pg_upgrade.
- Fixed a segmentation fault caused by foreign data wrapper invalidation during autonomous transactions if an autonomous transaction reset global variables while registered callback functions remained active. Now callback functions check for global variables and invalidation data is preserved for parent transactions.
- Fixed an issue that caused the server to crash with PANIC instead of returning an appropriate error when deleting tuples from a page where the difference between the minimum transaction ID and the current transaction ID exceeded 2^31.
- Fixed `pg_multixact` bloating by introducing “soft” limits that trigger autovacuum earlier.
- Fixed an issue where `crash_info` could fail to write diagnostic files when handling a stack overflow. Previously, the signal handler ran on the same stack that had overflowed, which could prevent it from executing due to lack of available stack space. Now the handler runs on an alternate signal stack.
- Fixed a memory context issue, which could previously cause emitting garbage in logs instead of the host and port details when disconnecting from the remote server.
- Fixed an issue that could occur when a custom scan was used, which could cause an incorrect state of the query plan and could result in an error when pgpro_stats was involved.
- Fixed an issue where roles without explicitly set `VALID UNTIL` attribute and associated with a profile that had PASSWORD_GRACE_TIME set to 0 and `PASSWORD_LIFE_TIME` set to `UNLIMITED` incorrectly received password expiration warnings. Now they are correctly considered valid indefinitely.
- Fixed a bug that caused problems with starting followers added after execution of `ALTER SYSTEM` on the initialized leader.
- Fixed an issue where temporary tables could fail to grow when their size exceeded a segment boundary, which could manifest itself in “could not open file” errors.
- Fixed an issue where parallel apply workers could not apply streaming transactions in logical replication (`streaming = parallel`). This issue occurred when the publisher sent transactions in 32-bit XID format.
- Upgraded the apache_age extension to version 1.5.1.
- Upgraded the BiHA solution to provide the following features, optimizations, and bug fixes:

  - Improved the `bihactl` init --convert command to skip the creation of objects required for BiHA cluster operation if these objects already exist in the database. Previously, the conversion would fail in such cases.
  - Improved the callbacks functionality. Added the `NODE_ADDED`, `NODE_REMOVED`, and `LEADER_STATE_IS_RW` callback types. Updated the `TERM_CHANGED` type. Added the `biha_callbacks_user` user role as the default user for callback execution.
  - Implemented the ability to decrease the max_connections configuration parameter in a BiHA cluster without turning off the biha extension. You can now decrease the parameter value on the leader node and restart the node for the changes to take effect. Previously, the `max_connections` value could only be decreased if you temporarily remove the biha extension from `shared_preload_libraries`.
  - Fixed a bug that caused the biha.nodes function to return an empty row for the node where it was called on.
  - Fixed a bug that caused the `biha-background-worker` process reboot when removing a replication slot.
  - Fixed a bug that caused problems with conversion of a cluster with the set shared_preload_libraries variable in the postgresql.auto.conf file into a BiHA cluster.
  - Fixed a bug that caused problems with conversion of a synchronous cluster into a BiHA cluster. Resetting the `synchronous_standby_names` parameter before conversion of a synchronous cluster is no longer required.
- Upgraded citus to version 12.1.6.1.
- Optimized fasttrun to skip unnecessary truncate operations on empty temporary relations.
- Upgraded mamonsu to version 3.5.11 to provide support for pgpro_stats version 1.8.
- Upgraded multimaster to add the ability to specify the catchup mode for reconnected nodes using the `multimaster.catchup_algorithm` configuration parameter. Supported the `parallel` catchup mode, in which non-conflicting replicated transactions are applied in parallel.
- Fixed an issue with upgrading pageinspect in some corner cases to 1.10.1 or higher.
- Added the pgpro_multiplan extension version 1.1, which includes the full functionality of the sr_plan extension as well as new features, such as `plan_hash` — the internal plan identifier of a frozen plan. The sr_plan extension is considered deprecated, and its support will end together with Postgres Pro Enterprise 16. Using pgpro_multiplan together with sr_plan is not allowed as it will lead to a replica failure in a high-availability cluster. More changes as compared to sr_plan are as follows:
  - Added support for `template` plans and the wildcards feature. Now the pgpro_multiplan extension can create a template plan, which can be applied to the queries with table names matching the `POSIX` regular expressions in the `pgpro_multiplan.wildcards` configuration parameter.
  - Fixed an issue with query execution when a plan was approved while pgpro_multiplan.auto_capturing was enabled, and then the query was executed with a different plan and `pgpro_multiplan.auto_capturing` was disabled. The issue could manifest itself in errors like “cache lookup failed for type”.
  - Fixed an issue with pgpro_multiplan failing to identify registered query with the parameter used in several places in this query, which prevented plan freezing for such queries.
- Upgraded pgbadger to version 13.0.
- Upgraded pgbouncer to version 1.24.0.
- Upgraded pg_hint_plan to version 1.6.1.2.
- Upgraded pg_portal_modify to version 0.3.5.
- Upgraded pgpro_anonymizer to version 1.3.2.
- Upgraded pg_proaudit to provide the following enhancements:
  - Added a new event field: session user name. Now an event contains the information about both `session_user` and `current_user` attributes of an SQL session.

    - Added support for new event classes: `ALL_DDL_NONTEMP` and `ALL_DML_NONTEMP`. The scope of these classes is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
    - Fixed logging of `SELECT FOR UPDATE` and `SELECT FOR KEY SHARE` events as `SELECT`, rather than `UPDATE`.
- Upgraded pg_probackup to version 2.8.7 Enterprise, which provides the following optimizations and bug fixes:
    - Reduced the log level for "checking WAL file name" messages that are issued when the `show` with the `--archive` option is executed from `INFO` to `VERBOSE`.
    - Updated the `add-instance` command logic to make the `-D` option that specifies the path to the catalog mandatory. `add-instance` no longer relies on the `PGDATA` environment variable for the catalog location, but requires explicitly specifying the path to the catalog as the command option.
    - Improved the garbage collection mechanism in CFS used when a backup copy is created. File-system level locks resolve an issue with the concurrent access to files from compressed tablespaces during copying to a backup and during the defragmentation.
    - Fixed an issue of the multi-threaded file copying technique that prevents repeated copying of one file. This issue could previously stop the backup creation under high load on the server.
- Upgraded pgpro_pwr to version 4.8, which provides new features and bug fixes. Notable changes are as follows:
    - Added tracking of extension versions installed in the cluster through a new report section.
    - Added a possibility to hide data for certain databases in the report. To this end, a new parameter that accepts an array of databases to be excluded was added to report generation functions.
- Upgraded pgpro_sfile to add a check for the value of the *a_sf_index* argument of the `sf_write` function to be greater than zero.
- Upgraded pgpro_stats to version 1.8.1, which provides the following bug fixes and improvements:
    - Fixed an issue that could occur during session tracing and cause errors "could not write file ""pg_stat/pgpro_stats_filters.trace.tmp"": No such file or directory". Concurrent writing from different sessions to a trace file is fixed now, so processes can write to the trace file in parallel without collisions.
    - Changed the format of the statistics dump file and the corresponding save/load routines.
    - Implemented an optimization that lowers the locking time in some cases when copying metrics from the local memory to the shared memory.
    - Aligned the names of the `explain_*` filter attributes of the session tracer with the names of session-tracing configuration parameters.
    - Implemented turning off the session tracer functionality when no session-tracing filters are specified.
- Upgraded pg_variables. The `DISCARD ALL` command now discards all packages and variables in pg_variables.
- Upgraded plpgsql_check to version 2.7.12.
- Upgraded the rum module to update an error message for an error that can occur in the case when a `SELECT` query uses `ORDER BY`.

E.4.2. Migration to Version 16.8.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

> **Important**
>
> To upgrade your BiHA cluster from Postgres Pro Enterprise 16.6 or earlier to Postgres Pro Enterprise 16.8, see the Migrating the BiHA Cluster to Version 16.8 section.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

When upgrading your high-availability cluster from Postgres Pro Enterprise versions 16.3.x or lower, first disable automatic failover if it was enabled and upgrade all the standby servers, then upgrade the primary server, promote a standby, and restart the former primary (possibly with pg_rewind).

If you take backups using pg_probackup and you have previously upgraded it to version 2.8.0 Enterprise or 2.8.1 Enterprise, make sure to upgrade it to version 2.8.2 Enterprise or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To upgrade your BiHA cluster from Postgres Pro Enterprise 16.4 or earlier to Postgres Pro Enterprise 16.6, see the Migrating the BiHA Cluster to Version 16.6 section.

To upgrade your BiHA cluster from Postgres Pro Enterprise 16.3 or earlier to Postgres Pro Enterprise 16.4, see the Migrating the BiHA Cluster to Version 16.4 section.

To upgrade your BiHA cluster from Postgres Pro Enterprise 16.1 and 16.2 to Postgres Pro Enterprise 16.3, see the Migrating the BiHA Cluster to Version 16.3 section.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.5. Postgres Pro Enterprise 16.6.1

Release Date: 2024-12-13

E.5.1. Overview

This release is based on PostgreSQL 16.6 and Postgres Pro Enterprise 16.4.2. All changes inherited from PostgreSQL 16.6 are listed in PostgreSQL 16.6 Release Notes. As compared with Postgres Pro Enterprise 16.4.2, this version also provides the following changes:

- Implemented preliminary check to determine whether new data provides sufficient basis for further query replanning. If no additional knowledge is available at the trigger point, query execution continues.
- Added the ability to form the `MergeAppend` operation instead of `Append`, which allows omitting additional sorting needed to ensure that the data is in fact sorted. Now `MergeAppend` is formed specifying the columns to sort by. The new ability applies only when the enable_appendorpath option is set to `ON`.
- Improved performance of CFS by reducing the number of invalidation messages for tables, which previously caused multiple file reopen events. Now invalidation is targeted at the specific segments affected by the garbage collector.
- In JSON files that store frozen plans, arrays of parameter types are now displayed in the text format instead of numeric, making it easier to edit an incorrect parameter type.
- Allowed transformation of correlated `IN` subqueries into joins.
- Implemented the ability to dump the state of a single backend process by sending the dump signal.
- Added a validation step to check for non-zero values in unused header fields of `*.cfm` files by pg_upgrade.
- Improved the real-time query replanning output: the “Total Execution Time” property was renamed “Total Elapsed Time”; a new “Final Run Planning Time” property was added, which represents the

planning time during the last reoptimization. Also the “Planning Time” field of EXPLAIN now includes the execution time of attempts aborted by real-time query replanning.

- Changed the error level to calculate the statistics on vacuum interrupts to ERROR (PGERROR) only. Calculating vacuum interrupts for the PANIC error level could cause unpredictable system behavior, and the statistics could not be calculated anyway because of the server crash.
- Deprecated the ability to create constructs using JSON_EXISTS() with the RETURNING clause. This syntax is not supported by the SQL/JSON standard, which states that the JSON_EXISTS() predicate should only return TRUE, FALSE, or UNKNOWN.
- Fixed a use-after-free bug that could lead to a segmentation fault when using both real-time query replanning and aqo.
- Fixed logging of replanning reasons. Previously, all replanning events were incorrectly logged with "Replanning triggered by timeout".
- Fixed a security bug in pgpro_sfile where SECURITY DEFINER functions did not manage search_path. This potentially allowed attackers to execute arbitrary code with superuser privileges.
- Fixed cfs_gc_relation to return the actual number of processed segments of the relation.
- Fixed an issue with upgrading from PostgreSQL or Postgres Pro Standard to Postgres Pro Enterprise using pg_upgrade when a multitransaction offset counter overflow occurred.
- Fixed the processing of 64-bit transaction IDs with proper encoding and decoding of the transaction ID.
- Fixed an issue with upgrading from PostgreSQL or Postgres Pro Standard to Postgres Pro Enterprise using pg_upgrade that could occur when attempting to convert heap pages to the double xmax page format in cases where there was insufficient free space to accommodate the special area. In the presence of multitransactions, this could lead to errors like “MultiXactId XXXXX has not been created yet” or “could not access status of transaction XXXXXX”, depending on the server version. No data loss is expected as the actual conversion did not occur. Pages will now be safely converted upon first access.
- Fixed a memory leak that could occur when the EXPLAIN command's output produced over 64 columns.
- Fixed a segmentation fault, which could occur while executing the COPY TO command when using the online_analyze module.
- Fixed an issue where EXPLAIN ANALYZE showed incorrect counts of inserted and conflicted tuples during row inserts with conflicting primary keys when using ON CONFLICT DO NOTHING.
- Fixed an issue that could slow down query execution. The reason was that the optimizer selected a suboptimal index due to the lack of its cost estimation after removing redundant clauses with the enable_appendorpath option set to ON.
- Fixed an issue in the parsing of prepared statement names when the statement name contained an SQL command name, and removed the no-longer-needed sr_plan.max_consts_len.
- Added support of the extended query protocol for the real-time query replanning.
- Added support for ARM architecture for Red OS Murom 8.
- Removed support for legacy data loading, previously required for reading obsolete sr_plan binary plans and converting them to the JSON format. A minimal functionality is retained to detect legacy files, back them up, and log a message.
- Upgraded aqo to include the following optimizations and bug fixes:
  - Introduced the aqo sandbox mode, which allows working in an isolated environment without touching the main aqo knowledge base. This mode can be turned on either on a primary or a standby node by setting aqo.sandbox to on.

  - Enhanced aqo wide search (`aqo.wide_search = on`) to utilize data from multiple neighbors simultaneously. Also, revised its interaction with `aqo.min_neighbors_for_predicting` to allow queries with fewer than the specified number of data samples to participate in wide search. Previously, such queries were excluded from consideration.
  - Fixed an array index out-of-bounds issue in the aqo smart statement timeout update logic, as well as incorrect statistics insertion into `aqo_query_stats` when the arrays were full. In previous releases, using `aqo_query_stat_update` with arrays of size 20 or more could lead to subsequent statistics updates being written to uncontrolled memory segments. Make sure to install the Postgres Pro on both primary and standby servers to avoid similar memory corruption problems.
- Improved the built-in high-availability feature to provide the following features, optimizations, and bug fixes:
  - Upgraded biha to version 1.4.
  - Implemented the callbacks to call custom SQL functions, which can notify users or external services about events in the BiHA cluster.
  - Implemented a mechanism that enables relaxed synchronous replication for the BiHA cluster. To relax synchronous replication restrictions, specify the `--sync-standbys-min` parameter when initializing the cluster with the `bihactl` init command, or later by means of the biha.set_sync_standbys_min function.
  - Added the biha.node_priority configuration parameter that allows you to manage voting by means of setting node priorities in the BiHA cluster.
  - Added the biha.set_nquorum and biha.set_minnodes functions to configure the biha.nquorum and biha.minnodes configuration parameters independently. Previously, these parameters could only be set together by the biha.set_nquorum_and_minnodes function.
  - Added the biha.can_vote and biha.can_be_leader configuration parameters that allow you to manage the ability of the BiHA cluster nodes to vote and stand as candidates in elections of the new leader correspondingly.
  - Added the biha.flw_ro configuration parameter that allows you to determine whether a node can be available for read operations.
  - Implemented a mechanism that automatically disables reading from the node in the `NODE_ERROR` state.
  - Updated the biha.nodes_v view. The view table now also displays the node that the view is queried on.
  - Changed the way the GUC parameters essential for biha operation are managed. Previously, manual modification of the following parameters was not forbidden: primary_conninfo, primary_slot_name, synchronous_standby_names. However, manual change of the above mentioned parameters could have negative impact on the BiHA cluster operation. Now, when biha is loaded and configured, these parameters are managed by biha only, and you cannot modify them with `ALTER SYSTEM`.
  - Optimized the behavior of the BiHA cluster when replication cannot proceed due to deletion of the required WAL files determined in the `max_slot_wal_keep_size` parameter. In this situation, the node that falls behind transfers to the `NODE_ERROR` state.
  - Fixed a bug that caused the reboot of a leader candidate in case it does not know the ID of the old leader.
  - Fixed an issue with the data directory size growth on the referee node in `referee_with_wal` mode.
  - Fixed a bug that caused authentication issues when setting up a BiHA cluster from the existing cluster. The biha extension now uses the same password encryption algorithm that is set in the `postgresql.conf` file of the converted primary node.

- Upgraded citus to version 12.1.5.2.
- Upgraded mamonsu to version 3.5.9, which provides optimizations and bug fixes. Notable changes are as follows:
  - Added support for systems where *setuptools* version greater than 67.7.2 is installed.
  - Ended the use of dotted `user:group` specification at the RPM pre-install stage.
- Upgraded multimaster to version 1.2.0. Significantly increased catchup performance by enabling asynchronous commit operations on a lagging node syncing with the donor node, controlled by the `multimaster.enable_async_3pc_on_catchup` parameter.
- Upgraded the ODBC driver to version 17.00.0002.
- Upgraded oracle_fdw to version 2.7.0.
- Upgraded orafce to version 4.13.5.
- Upgraded pg_filedump to version 17.1, which specifically fixed an issue that could cause pg_filedump to crash with a segmentation fault when handling incomplete pages.
- Upgraded pg_hint_plan to version 1.6.1.
- Upgraded pg_integrity_check to display actual checksum values, if the checksums differ, only with the `--verbose` option.
- Upgraded pg_portal_modify to version 0.3.4.
- Upgraded pg_proaudit to provide the following optimizations and bug fixes:
  - Added logging of security events related to operations with profiles: `CREATE PROFILE`, `ALTER PROFILE`, and `DROP PROFILE`.
  - Changed the distribution of security events related to functions and stored procedures among the groups of security events: the `ALL_DDL` group now includes no events related to functions and stored procedures, `ALL_PROC` includes `CREATE`, `ALTER`, and `DROP`, while `ALL_DML` includes `EXECUTE`.
  - Fixed compatibility with the connection pooler. Previously, issues could be encountered when logging `AUTHENTICATE` and `DISCONNECT` security events.
  - Fixed logging of security events on partitioned tables by pg_proaudit. Now the `SELECT/UPDATE/INSERT/DELETE/TRUNCATE` events on a partitioned table get logged if logging rules imply logging of appropriate events for this table. Previously, only events on individual partitions were logged.
- Upgraded pg_probackup to version 2.8.5 Enterprise, which provides the following optimizations and bug fixes:
  - Enabled the output of the `version` command in the JSON format using `--format=json`.
  - Added the `--all` option to the `amcheck` command, which allows performing all the checks in a single command.
  - Added support for the `include` parameter in the configuration file. The contents of the file specified in `include` gets added to the configuration file instead of this parameter.
  - Added a possibility to specify an individual number of threads for execution of a backup and its subsequent validation by specifying the `--backup-threads` and `--validate-threads` option, respectively.
  - Changed the priority of setting `PGDATA` and `BACKUP_PATH`. Now the values from the command-line options take precedence.
  - Added validation of WAL files for backups to be merged by the `merge` command.
  - An error message that was issued when the `validate` command run with the `--wal` option found an archive in the `DEGRADED` status has been replaced with a warning since backups in this status do not affect the restore correctness as a whole.

  - Added support for the `--s3-config-file` option of `restore_command`. `postgresql.auto.conf` must include the `restore_command` with the `--s3-config-file` option if the backup was created with this option.
  - The default value of `PG_PROBACKUP_S3_IGNORE_CERT_VER` is set to `on` according to the documentation.
  - Fixed an issue that could occur if the command line was too long.
  - Fixed an issue that could occur during validation or restore when the PITR from a previous timeline was performed.
  - Fixed an issue that could occur when the S3 connection port was specified both in `PG_PROBACKUP_S3_PORT` and `PG_PROBACKUP_S3_HOST`. Now the value specified in `PG_PROBACKUP_S3_HOST`, together with the address, has higher priority.
- Upgraded pgpro_bfile to version 1.2, pgpro_sfile to version 1.2, and pgpro_rp to version 1.1. Functions that previously checked whether certain functions were called by a superuser now only check that those functions are called with superuser privileges.
- Upgraded pgpro_controldata to version 17.1.0.
- Upgraded pgpro_stats to version 1.8, which supports Postgres Pro 17. Notable changes are as follows:
  - Updated `pgpro_stats_statements` and `pgpro_stats_totals` views to include fields added to pg_stat_statements. Related functions were updated accordingly.
  - Streamlined access to views and functions. Specifically, access to the `pgpro_stats_archiver`, `pgpro_stats_vacuum_database`, `pgpro_stats_vacuum_tables`, and `pgpro_stats_vacuum_indexes` views was granted to all users. Previously, these views required explicitly granting access rights. Access to execution of the `pgpro_stats_trace_reset` function, which could previously be executed by any user, was restricted to superusers.
  - Implemented an optimization that lowers the locking time in some cases when copying metrics from the local memory to the shared memory.
  - Eliminated an excessive check of holding the lock when accessing the hash table of session-tracing filters.
  - Fixed processing of the `pgpro_stats.stats_temp_directory` configuration parameter. Previously after the server restart for changes to this parameter value to take effect, the fatal error “pfree called with invalid pointer” could occur when processing this parameter.
  - Fixed an issue that could occur during session tracing and cause errors “could not write file ""pg_stat/pgpro_stats_filters.trace.tmp"": No such file or directory”. Concurrent writing from different sessions to a trace file is fixed now, so processes can write to the trace file in parallel without collisions.
- Upgraded pgpro_pwr to version 4.7, which provides new features, optimizations and bug fixes. Notable changes are as follows:
  - A *subsample* feature to collect relatively fast changing data.
  - New report tables, specifically regarding session states.
  - Support for new Postgres Pro 17 statistics.
  - A possibility not to reset statistics of the statistics collecting extension during taking a sample.
  - The change of the type for the field that tracks transaction IDs in a certain table from `xid` to `text`. The use of the `xid` type could previously cause a failure of pg_upgrade when upgrading from Postgres Pro Standard to Postgres Pro Enterprise.
- Upgraded pgpro_scheduler to version 2.10, which provides the following changes:
  - Fixed an issue with automatic restart of one-time jobs after job interruption.
  - Fixed `schedule.get_active_jobs` to properly return the list of currently executed cron jobs.

  - Fixed an issue where errors occurring during job execution were not properly logged due to a primary key constraint preventing multiple log entries.
  - Fixed an issue where `at job executor` would fail when the `database manager` prematurely released the shared memory segment before the worker had connected to it.
  - Fixed an issue where `schedule.timetable` did not display the next execution time of cron jobs with either `next_time_statement` or an array of dates. Fixed an issue with calculating next execution time for cron jobs that caused job instances to be skipped.
  - Fixed an issue causing database crashes due to segmentation faults in the job executor background worker.
- Upgraded pg_repack to version 1.5.1.
- Upgraded pg_wait_sampling to provide tracking of subquery IDs and utility statements and to add the new `pg_wait_sampling.sample_cpu` parameter, which allows specifying the sampling mode that determines whether to perform sampling of on-CPU backends.
- Upgraded pljava to version 1.6.8.
- Upgraded the PLV8 extension to version 3.2.3.
- Ensured compatibility of `postgres_fdw` with autonomous transactions.
- Upgraded PTRACK to prevent possible issues with PTRACK backups by setting the `ptrack.map` file for automatic deletion when PTRACK is disabled.
- Upgraded tds_fdw to version 2.0.4.

E.5.2. Migration to Version 16.6.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

> **Important**
>
> To upgrade your BiHA cluster from Postgres Pro Enterprise 16.4 or earlier to Postgres Pro Enterprise 16.6, see the Migrating the BiHA Cluster to Version 16.6 section.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

When upgrading your high-availability cluster from Postgres Pro Enterprise versions 16.3.x or lower, first disable automatic failover if it was enabled and upgrade all the standby servers, then upgrade the primary server, promote a standby, and restart the former primary (possibly with pg_rewind).

If you take backups using pg_probackup and you have previously upgraded it to version 2.8.0 Enterprise or 2.8.1 Enterprise, make sure to upgrade it to version 2.8.2 Enterprise or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To upgrade your BiHA cluster from Postgres Pro Enterprise 16.3 or earlier to Postgres Pro Enterprise 16.4, see the Migrating the BiHA Cluster to Version 16.4 section.

To upgrade your BiHA cluster from Postgres Pro Enterprise 16.1 and 16.2 to Postgres Pro Enterprise 16.3, see the Migrating the BiHA Cluster to Version 16.3 section.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.6. Postgres Pro Enterprise 16.4.2

Release Date: 2024-10-24

E.6.1. Overview

This release is based on Postgres Pro Enterprise 16.4.1 and provides the following changes:

- Introduced various optimizations in the implementation of improved performance for subsystems on top of SLRU, including more consistent use of `int64` and acquiring the correct SLRU bank lock. The latter fixes an issue with zeroed `pg_serial` pages, which could manifest itself in “could not access status of transaction” errors.
- Fixed an issue to avoid potential stack overflow in scenarios involving a large number of subtransactions. Now when handling the process of committing a transaction, iteration is used instead of tail recursion.
- Fixed an issue that caused a terminated CFS worker to respawn with a duplicate with the same worker ID. This led to multiple instances of the same worker competing for the recovery of compressed segments.
- Fixed a race condition in committing serializable transactions.
- Fixed an issue in `pg_serial`, which could arise when the transaction counter reached values over 2^{32}.
- Fixed a memory leak in `walsender` in multimaster.

E.6.2. Migration to Version 16.4.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.7. Postgres Pro Enterprise 16.4.1

Release Date: 2024-09-09

E.7.1. Overview

This release is based on PostgreSQL 16.4 and Postgres Pro Enterprise 16.3.2. All changes inherited from PostgreSQL 16.4 are listed in PostgreSQL 16.4 Release Notes. As compared with Postgres Pro Enterprise 16.3.2, this version also provides the following changes:

- Enhanced performance of segment search by implementing a new search strategy, allowing faster detection of the last segment.
- Lowered the number of unneeded replanning attempts by adding the backend memory consumption trigger, whose value is defined by the replan_memory_limit configuration parameter, and changing the replanning behavior triggered by the number of processed node tuples.
- Implemented the interaction of the PASSWORD_GRACE_TIME profile parameter with the `VALID UNTIL` role attribute. Now if both of them are set, the warning about password expiration will be displayed.
- Prevented potential authentication delays due to locking by not updating role's last login time if the role's profile `USER_INACTIVE_TIME` is set to unlimited (see Section 56.40 for details).
- Optimized the logic of pruning, which is now delayed until a page is nearly full, rather than relying solely on the fill factor. This reduces the frequency of pruning during `UPDATE` operations, leading to better performance in tables with frequent updates.
- Fixed an issue with statistics handling in autonomous transactions. Previously, statistics changes were only saved if both the autonomous transaction and the parent transaction were commit-

ted successfully. This oversight was usually pretty harmless since no reported failures have been traced.

- Fixed an issue with nested loop parameters that forced Memoize to constantly purge the cache. This bugfix speeds up query execution.
- Fixed issues related to processing of data structures in CFS by pg_rewind. Previously, pg_rewind did not fully support CFS, which could result in data corruption.
- Fixed a segmentation fault that could occur when a connection to the built-in connection pooler was reset before a new session was created in the backend.
- Fixed an issue with freezing 64-bit multitransaction IDs, which could manifest itself in PANIC-level errors like “xid XXX does not fit into valid range for base YYY” during autovacuum.
- Fixed an issue related to suboptimal handling of `pd_prune_xid`. This issue did not result in any significant operation problems but caused unnecessary page pruning, which might have produced extra WAL records.
- Fixed an issue, which could manifest itself in errors like “invalid FSM request size”. The code was adjusted to reflect the changes in heap page structure, removing reliance on a constant related to maximum free heap page space where it is no longer applicable.
- Fixed a bug that caused the optimizer to ignore columns from query conditions. Previously, when partially using a composite index, the number of rows could be overestimated, which led to an incorrect plan creation. The bug occurred due to a malfunction of the multi-column statistics elements.
- Fixed a bug in `ANALYZE` that could occur because it was impossible to display the `pg_statistic` system catalog. For the fix to work, if your database has indexes with `INCLUDE` columns, after upgrading Postgres Pro, it is recommended to do another `ANALYZE` for these columns.
- Added support for ALT 11.
- Upgraded the PostgreSQL ODBC driver to version 16.00.0005.
- Improved the built-in high-availability feature to provide the following optimizations and bug fixes:
  - Upgraded biha to version 1.3.
  - Optimized the automatic rewind logic. Now if the biha.autorewind configuration parameter is set to `false` on the node and cluster timelines diverge, this node stops accepting WAL records after it goes into the `NODE_ERROR` state. Based on the new logic, to execute queries on the node, remove `biha` from `shared_preload_libraries` on this node and/or run the manual rewind. The rewind results can now be checked in the `rewind_state` field of the `biha.state` file.
  - Optimized behavior of the synchronous referee node in the `referee_with_wal` mode, which now depends on the synchronous_commit value.
  - Fixed an issue that could cause the leader node to accidentally demote. This happened because all follower nodes, which were executing queries, crashed due to a conflict between a query and the recovery process. Now the extension throws a warning instead of crashing.
  - Fixed a segmentation fault that could occur in the control channel while trying to remove a node from the cluster.
  - Fixed memory leaks in bihactl.
- Upgraded citus to version 12.1.5.1, which now supports the ability to use the extension together with the enabled enable_group_by_reordering configuration parameter.
- Upgraded dbms_lob to version 1.2, which now supports reading and writing blocks up to 1GB, an increase from the previous 32KB limit.
- Added the hypopg extension, which provides support for hypothetical indexes in Postgres Pro.
- Upgraded the mchar extension to fix a bug that caused the `mchar` and `mvarchar` data types to ignore control characters during string comparison.

- Implemented the ability to slow down transaction execution on the donor node in multimaster using the `multimaster.tx_delay_on_slow_catchup` configuration parameter. This is useful when a lagging node is catching up to the donor node and cannot apply changes as quickly.
- Upgraded pg_filedump to version 17.0, which provides optimizations and bug fixes. In particular, contents of meta pages for GIN and SP-GiST indexes are now displayed correctly, and an issue of lacking memory for encoding and decompression is resolved.
- Upgraded pg_proaudit to provide the following optimizations and bug fixes:
  - Improved performance and added the `pg_proaudit.max_rules_count` parameter, which allows specifying the maximum number of rules allowed.
  - Corrected support of database names including uppercase symbols by the `pg_proaudit_set_rule` function.
- Upgraded pg_probackup to version 2.8.3 Enterprise, which provides the following bug fixes:
  - Fixed backup validation for databases containing an OID larger than 10^9. Previously, the validation status could be displayed incorrectly in such cases.
  - Fixed a bug that could occur when pg_probackup was run as a user included in the `postgres` group in case the database used CFS.
- Upgraded the pgpro_rp extension to version 1.1, which now supports plan assignment groups. The database administrator can now create plan assignment groups for different roles to control resource prioritization across large amounts of database users.
- Upgraded pgpro_sfile to version 1.2, which adds the `sf_md5` function that calculates MD5 hash for an `sfile` object.
- Upgraded pgvector to version 0.7.4.
- Fixed incorrect behavior of pg_wait_sampling when used with the extended query protocol.
- Upgraded sr_plan to provide new features and optimizations. Notable changes are as follows:
  - Added the sr_plan.sandbox configuration parameter that allows testing and analyzing queries without affecting the node operation by reserving a separate area in shared memory for the nodes.
  - Added three configuration parameters sr_plan.auto_capturing, sr_plan.max_captured_items, and `sr_plan.max_consts_len` that allow you to configure query capturing.
  - Added the sr_captured_queries view that displays information about queries captured in sessions.
  - Added the sr_captured_clean function that removes all records from the `sr_captured_queries` view.
  - Renamed the `sr_plan.max` configuration parameter to sr_plan.fs_ctr_max.
  - Replaced `queryid` with `sql_hash` to reflect the new query identification logic.
- Upgraded utl_http to provide support for `PUT`, `UPLOAD`, `PATCH`, `HEAD`, `OPTIONS`, `DELETE`, `TRACE`, as well as any custom HTTP methods.

E.7.2. Migration to Version 16.4.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

> **Important**
>
> To upgrade your BiHA cluster from Postgres Pro Enterprise 16.3 or earlier to Postgres Pro Enterprise 16.4, see the Migrating the BiHA Cluster to Version 16.4 section.

> **Important**
>
> When upgrading your high-availability cluster from Postgres Pro Enterprise versions 16.3.x or lower, first disable automatic failover if it was enabled and upgrade all the standby servers, then upgrade the primary server, promote a standby, and restart the former primary (possibly with pg_rewind).

If you take backups using pg_probackup and you have previously upgraded it to version 2.8.0 Enterprise or 2.8.1 Enterprise, make sure to upgrade it to version 2.8.2 Enterprise or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To upgrade your BiHA cluster from Postgres Pro Enterprise 16.1 and 16.2 to Postgres Pro Enterprise 16.3, see the Migrating the BiHA Cluster to Version 16.3 section.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.8. Postgres Pro Enterprise 16.3.2

Release Date: 2024-07-02

E.8.1. Overview

This release is based on Postgres Pro Enterprise 16.3.1 and provides the following changes:

- Fixed two issues that could occur after upgrading from PostgreSQL or Postgres Pro Standard using pg_upgrade: fixed `xid` base calculation during heap page pruning and `xmax` calculation during page conversion from 32-bit to 64-bit format. These issues didn't result in data loss or corruption but raised PANIC-level errors.
- Fixed a segmentation fault caused by improper memory management in CFS, which could occur in some corner cases where CFS garbage collector was disabled or a standby server restored WAL records for a long time (e.g. it was lagging far behind).
- Fixed a bug in the backend composite type cache management. This bug could result in a segmentation fault or produce errors like “ERROR: record type has not been registered” during the process of selectivity estimation in query planning under the following conditions:
  - The query contained at least one `JOIN` operator.
  - The enable_compound_index_stats configuration parameter was enabled.
  - The tables involved in the query had multi-column `INCLUDE` indexes.
- Upgraded pgpro_sfile to version 1.1, which provides two bug fixes:
  - Fixed an issue with the sf_read function where reading from an offset greater than 8096 bytes would return data from the beginning of the `sfile` object.
  - Fixed copying of `sfile` column values in binary format.
- Upgraded orafce to version 4.10.3.
- Upgraded pg_probackup to version 2.8.2 Enterprise, which provides the following bug fixes:
  - Fixed an OID parsing issue where databases and tablespaces with relfilenodes greater than a billion were not included in backups.
  - Fixed an issue in enabling pg_probackup logging with the `--log-level-file` parameter, where the parameter value was written to the configuration file, but no directory for log files was created.

E.8.2. Migration to Version 16.3.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

> **Important**
>
> If you take backups using pg_probackup and you have previously upgraded it to version 2.8.0 Enterprise or 2.8.1 Enterprise, make sure to upgrade it to version 2.8.2 Enterprise or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.9. Postgres Pro Enterprise 16.3.1

Release Date: 2024-06-03

E.9.1. Overview

This release is based on PostgreSQL 16.3 and Postgres Pro Enterprise 16.2.2. All changes inherited from PostgreSQL 16.3 are listed in PostgreSQL 16.3 Release Notes. As compared with Postgres Pro Enterprise 16.2.2, this version also provides the following changes:

- Disabled the system startup timeout by setting the `TimeoutSec` parameter to 0 in systemd. Previously, big databases could fail to start within the specified timeout.
- Reduced logging level during a specified restore point creation at a checkpoint timeout for inactive bases only. It allows removing excessive log messages.
- Improved performance of subsystems on top of SLRU. This includes improvements for the LWLocks that changed the locking mode for the SLRU banks, so that each bank uses a separate LWLock. This results in increased scalability. Also, a new concurrency model for SLRU implementation that uses atomic reads and writes is proposed.
- Introduced new features, optimizations and bug fixes for CFS. Notable changes are as follows:
  - Added the cfs_log_verbose configuration parameter that controls the CFS log level of defragmentation messages. It allows reducing the number of CFS messages in the log file.
  - Added the cfs_gc_lock_file configuration parameter that sets the path to the lock file to be used to ensure running only one garbage collection worker at a time for several Postgres Pro servers.
  - Modified the logic of truncating `*.cfm` files in CFS to improve performance. Previously, files were processed even if the file size didn't change, which could be unexpectedly heavy. The new approach involves checking the file size and only truncating if the size differs from the desired size to reduce unnecessary system calls.
  - Reduced the overhead of file size determination during query planning, particularly for queries involving numerous partitioned tables, which could be especially costly for CFS. Now file size is determined directly from the header without fully opening the file.
  - Fixed an issue in CFS, which could cause GC worker to fail with warning “CFS GC failed to read block 0 of file X at position 0 size 0: Success”. It happened due to incorrect handling of the first MB of the data file containing only zero pages.
- Added the xml_parse_huge configuration parameter that allows allocating up to 1 GB of memory for processing XML data.
- Fixed a bug resulting in error “cache lookup failed for collation 128”. Now, for the additional `INCLUDE` index columns, collation is ignored.
- Fixed two planner issues. An expression duplication issue previously caused underestimation of node selectivity and cost in some cases, which could lead to a choice of a suboptimal plan. Another

issue — the selectivity overestimation for an `AppendOr` node was caused by its subnode selectivity overestimation and led to the plan cost overestimation.

- Fixed an issue of not streaming certain data to a subscriber by a logical replication after executing the `ALTER PUBLICATION pub ADD TABLE tab` command. The root cause of the issue was an insufficient interlocking between `ALTER PUBLICATION` and taking a snapshot.
- Fixed an issue with the automatic aggressive vacuum being triggered too often. Now, an aggressive vacuum scan will only occur for any table with multixact-age strictly greater than autovacuum_multixact_freeze_max_age.
- Added support for Astra Linux 1.8 and ended support for Astra Linux Orel 2.12, Astra Linux Smolensk 1.6.
- Added support for Red OS Murom 8.
- Added support for Ubuntu 24.04.
- Upgraded aqo to version 2.1, which added the aqo.wal_rw configuration parameter to enable physical replication and allow complete aqo data recovery after failure.
- Upgraded biha to version 1.2, which provides new features and bug fixes. Notable changes are as follows:
  - Implemented the ability to add the referee node in biha, which allows setting up the 2+1 high-availability cluster with two regular nodes and one referee node. The referee is used only during elections and helps to avoid potential split-brain issues if your cluster contains only two nodes, i.e. the leader and one follower. Note that it does not contain any user databases and cannot be used for data querying.
  - Fixed an issue that could cause a cluster to fail when trying to call the biha.set_leader function to promote each follower manually.
  - Fixed a segmentation fault that could occur when a node started after a manual rewind using pg_rewind. Now the node can restore automatically after the rewind.
  - Fixed a bug related to alive node removal using biha.remove_node, which could cause leader re-elections after the removal. Now the node must be stopped before removing.
- Upgraded citus to version 12.1.3.1.
- Added the dbcopies_decoding 1C module for updating database copies. It is implemented as a logical replication plug-in and provided in `postgrespro-ent-16-contrib`.
- Upgraded dbms_lob to version 1.1, which includes necessary adjustments to provide interoperability with the new pgpro_sfile extension.
- Upgraded mamonsu to version 3.5.8, which provides optimizations and bugfixes. Notable changes are as follows:
  - Added support for the Zabbix 6.4 API: handling of deprecated parameters for authentication requests.
  - Removed caching of the `pgsql.connections[max_connections]` metric.
  - Updated the default log rotation rules.
  - Prepared for support of Python 3.12.
  - Changed metric names of the pg_locks plugin. Be aware that the changes could break custom user-defined triggers and processing functions that use the *`item.name`* parameter.
  - Fixed type mismatch for pgpro_stats and pg_wait_sampling.
  - Fixed privileges for the `mamonsu` role created by `bootstrap`.
- Upgraded orafce to version 4.10.0.
- Upgraded pg_probackup to version 2.8.0 Enterprise, which provides new features, optimizations and bug fixes. Notable changes are as follows:

    - Added a possibility to limit the rate of disk writes using the option `--write-rate-limit=bitrate (Mbps, Gbps)`.
    - Decreased the memory consumption when restoring long sequences of increments twice on average.
    - Added checksum validation for CFS files by `checkdb`.
    - Added a possibility to validate only a WAL archive.
    - Extended the use of the `--dry-run` option for all pg_probackup commands.
    - Made creation of a temporary slot during backups in the STREAM mode the default behavior unless it is specified otherwise.
    - Changed the default compression algorithm to `zstd`. If `zstd` is not supported by the system, `lz4` has the next priority. The `--compress` option now sets the default values for `--compress-level` and `--compress-algorithm`.
    - Added a possibility to specify several hosts to connect to an S3 storage.
    - Implemented a new locking technique, which enables using the locks with S3 and NFS protocols.
- Added the pgvector extension that provides vector similarity search for Postgres Pro.
- Added the pgpro_sfile module, which is similar to Oracle LOBs. It allows storing multiple large objects, called *`sfile` objects*. The maximum number of such objects as well as object size in bytes is limited by 2^63 - 1.
- Upgraded pgpro_stats to version 1.7.1, which provides optimizations and bug fixes. Notable changes are as follows:
    - Added saving non-normalized plans to pgpro_stats for queries where previously no plans were saved.
    - Fixed an issue that hindered the monitoring when the `pgpro_stats_statements` view contained quite a few rows with the same values of `plan` and `queryid`, but different values of `planid`. The issue was caused by an error in parsing the plan tree containing a `T_Memoise` node.
- Fixed an error “ERROR: query failed: ERROR: tablespace "XXXX" does not exist” that could occur when the `pg_repack` command was trying to reorganize tables in a tablespace whose name started with a digit. The root cause of the issue was that pg_repack expected extra quotes.
- Added the pljava module that brings Java stored procedures, triggers, and functions to the Postgres Pro backend.
- Added the plpgsql_check extension that provides static code analysis for PL/pgSQL in Postgres Pro.
- Upgraded sr_plan to provide new features, optimizations and bug fixes. Notable changes are as follows:
    - Added the `sr_plan_hintset_update` function, which allows changing the generated hint set with the set of custom hints.
    - Added the `sr_plan.max_local_cache_size` configuration parameter, which allows setting the maximum size of local cache, in kB. Also, the default value of `sr_plan.max_items` has been changed to 100.
    - Restricted query registration process so that only one query can be registered per backend.
    - Improved the algorithm for identifying a frozen query.
    - Implemented storage of query plans as separate JSON files.
    - Implemented type handling to attempt casting constants in the query to match the types of frozen query parameters automatically. If type casting is not possible, the frozen plan is ignored.
    - Removed the query tree validation for hint-set plans, allowing the use of hint-set plans during table recreations, field additions, etc.

E.9.2. Migration to Version 16.3.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

> **Important**
>
> To upgrade your BiHA cluster from Postgres Pro Enterprise 16.1 and 16.2 to Postgres Pro Enterprise 16.3, see Migrating the BiHA Cluster to Version 16.3 section.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.10. Postgres Pro Enterprise 16.2.2

Release Date: 2024-04-09

E.10.1. Overview

This release is based on Postgres Pro Enterprise 16.2.1 and provides the following changes:

- Increased the maximum value of the `slru_buffers_size_scale` configuration parameter to 9. In some high-load environments, the former maximum value was not sufficient and could result in query queuing and locks.
- Fixed incorrect HOT chain conversion from 32-bit to 64-bit after upgrading Postgres Pro Enterprise using pg_upgrade. The previous fix for this type of problem failed to account for changing the offset information after checking dead tuples.
- Fixed inconsistency of the `XMAX` value and the `XMAX_INVALID` hint bit of the tuple, which manifested itself in “missing chunk number 0 for toast value XXX in pg_toast_XXX” errors.
- Upgraded pgpro_pwr to version 4.5.
- Upgraded pg_probackup to version 2.7.3 Enterprise, which provides optimizations and bug fixes. Notable changes are as follows:
  - Added the `--waldir` option to the `catchup` command, which allows you to specify the directory to write WAL files to.
  - Fixed incremental restore of tables larger than 1GB. Checksum computation for file pages was fixed, so the tables will no longer be reread from the backup during restore.
  - Fixed an abnormal termination of pg_probackup upon a forced termination of a backup.
  - Fixed slow validation and restore of large databases by fixing file comparison. Previously, the file sorting algorithm used for the comparison could result in quadratic complexity.
  - Fixed an issue that could occur during a backup in the root of an S3 bucket.
- Upgraded sr_plan to provide optimizations and bug fixes.

E.10.2. Migration to Version 16.2.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.11. Postgres Pro Enterprise 16.2.1

Release Date: 2024-03-01

E.11.1. Overview

This release is based on PostgreSQL 16.2 and Postgres Pro Enterprise 16.1.1. All changes inherited from PostgreSQL 16.2 are listed in PostgreSQL 16.2 Release Notes. As compared with Postgres Pro Enterprise 16.1.1, this version also provides the following changes:

- Added real-time query replanning, which enables replanning of a query if some trigger indicates its non-optimal execution. Replanning is turned off by default and can be turned on with the replan_enable configuration parameter.
- Introduced two new modifiers for working with packages: `#private` and `#export`. The `#private` modifier defines functions and procedures as private, and the `#export` modifier defines which package variables are public.
- Added configuration parameters to enable getting information on crashes of a backend. The crash_info parameter turns on this functionality, while crash_info_dump and crash_info_location specify the contents and location of crash information files, respectively.
- Added a new configuration parameter cfs_gc_respond_time, which allows specifying the time interval that CFS waits for the lock to be released from a file processed by garbage collector before writing a warning to the log.
- Optimized memory consumption during selectivity estimation for each array element as compared to vanilla PostgreSQL.
- Optimized invalidation of the local relation cache when a temporary table tuple or an index tuple in the `pg_class` is not updated in case of the relation truncation.
- Updated the default values of default_toast_compression and wal_compression to `lz4`. It speeds up WAL and TOAST processing and reduces disk space utilization.
- Fixed a segmentation fault that could sometimes occur due to an oversight in a previous `GROUP BY` optimization.
- Fixed incorrect HOT chain conversion from 32-bit to 64-bit after upgrading Postgres Pro Enterprise using pg_upgrade. Previously, it resulted in the vacuum infinite loop. The number of vacuum retries is now limited to one per tuple. When exceeded, an error is written to the log.
- Fixed the race condition between the autovacuum worker and backend processes when clearing orphaned tables, which could manifest itself in “cache lookup failed for relation” errors. Now autovacuum locks the namespaces when clearing orphaned tables.
- Fixed an issue that could occur during installation of a Postgres Pro server on Debian-based systems included in a domain with the `postgres` user.
- Fixed the output of pg-setup , which erroneously displayed the locale from the `LANG` environment variable at cluster initialization. Now the message about locale is not displayed at this stage.
- Fixed an issue that could occur when a CFS garbage collection worker process failed. Because the worker did not restart automatically, the server restart was needed to continue. Now the worker gets restarted after 10 seconds of its unavailability.
- Ended support for Rosa Enterprise Linux Server 7.
- Ended support for ROSA COBALT (server edition) based on Rosa platform 7.
- Added the apache_age extension that provides graph database functionality.
- Upgraded biha to version 1.1, which provides optimizations and bug fixes. Notable changes are as follows:
  - Added configuration parameters used to specify logging levels for the biha components.
  - Fixed an issue with missing WAL files on the target server after synchronization of the former leader node using pg_rewind. The issue was caused by the wal_keep_size default value of zero. Now, if not specified by the user, bihactl sets the value to `1GB`.
  - Fixed excessive logging in the `NODE_ERROR` state.

- Ensured compatibility with the citus extension that provides the following additional capabilities: sharding, distributed tables, reference tables, a distributed query engine, columnar storage, and the ability to execute DML queries on any node. This extension enables you to arrange columnar data storage and, if required, scale your Postgres Pro installation to a distributed database cluster. Note that there are some limitations when using citus.
- Added the dbms_lob extension that allows accessing and manipulating specific parts of a LOB or complete LOBs. Note that only `CLOB`, `BFILE`, and temporary `BLOB` objects are supported for now.
- Upgraded orafce to version 4.9.2.
- Upgraded pg_probackup to version 2.7.2 Enterprise, which provides optimizations and bug fixes. Notable changes are as follows:
  - Optimized the use of memory during backups in the remote mode.
  - Fixed an issue that occurred during an incremental backup when a table that was not yet copied got removed from CFS.
  - Fixed the order of processing WAL files by the `archive-push` command when the number of WAL files exceeds the specified `--batch-size`.
  - Fixed an error “WAL segment is absent” that could occur when the size of a WAL record being logged exceeded the size of a WAL segment.
  - Fixed a bug that occurred when creating a versioned bucket in VK Cloud.
  - Fixed segmentation fault that occurred during execution of the `merge` command in S3.
- Upgraded pg_repack to version 1.5.0.
- Upgraded pg_variables, which now provides iterator functionality for any collections, as well as functions to work with general collection variables. These functions allow accessing collection elements by a key that can have either integer or text type. These enhancements facilitate migration of Oracle code that processes collections.
- Upgraded pg_proaudit to version 2.0, which provides the following major changes and enhancements:
  - Added new functions `pg_proaudit_set_rule` and `pg_proaudit_remove_rule` that allow creating and removing logging rules, respectively. These functions replaced `pg_proaudit_set_object`, `pg_proaudit_set_role`, `pg_proaudit_reset_object`, and `pg_proaudit_reset_role`.
  - Implemented the ability to log groups of events by specifying the respective value in the *`event_type`* argument.
  - Added the `comment` column in the `pg_proaudit_settings` view that displays the comment to describe the created logging rule.
  - Implemented the ability to log security events related to objects of the `PREPARED STATEMENT` type as well as events of the `DEALLOCATE`, `EXECUTE`, and `PREPARE` types.
  - Fixed an issue with incorrect logging of the `CREATE DATABASE`, `CREATE GROUP`, `CREATE ROLE`, `CREATE TABLESPACE`, and `CREATE USER` security events. Previously, these events were logged as `SUCCESS` after the syntax check and before the command execution itself. Now `SUCCESS` is written in the log when the command execution finishes, and if the command fails, it is marked as `FAILURE`.
- Upgraded pgpro_stats to version 1.7, which provides optimizations and bug fixes:
  - Similarly to a pg_stat_statements fix, changed pgpro_stats to read its “query texts” file in units of at most 1GB. Such large query text files are very unusual, but if they do occur, the previous coding would fail on Windows 64 (which rejects individual read requests of more than 2GB).
  - Implemented backward compatibility of `pgpro_stats_statements` and `pgpro_stats_totals` functions. Now a newer version of the pgpro_stats shared library can be safely used with old declarations of SQL functions. Previously such cases caused a server crash.

- Upgraded pgpro_pwr to version 4.4, which supports pgpro_stats 1.7, as well as adds more interactive features and substring-based filtering to the report.
- Upgraded the PLV8 extension to version 3.2.2.
- Upgraded sr_plan, which provides the following optimizations and bug fixes:
  - Implemented the ability to save different plans for the query with different sets of parameterized constants by using the unique pair of `queryid` and `const_hash` where `const_hash` is a hashed value of non-parameterized constants. This pair of keys replaced `srid`.
  - Implemented the ability to freeze query plans based on sets of hints, which can be viewed in the new `hintstr` column of the extension views.
  - Added the `sr_plan_local_cache` view, which provides detailed information about registered and frozen statements in the local cache.
  - Fixed an issue with the extension being unable to freeze the plan for the registered query, which could result in an out-of-memory failure when trying to freeze the same plan once again.
  - Fixed an issue with the deletion of the query plan storage file, which could occur upon Postgres Pro upgrades. Now a file backup is created to be able to roll back to the previous extension version and restore query plans.

E.11.2. Migration to Version 16.2.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the migration instructions for version 16.

E.12. Postgres Pro Enterprise 16.1.1

Release Date: 2023-12-25

E.12.1. Overview

This release is based on PostgreSQL 16.1 and includes all the new features introduced in PostgreSQL 16, as well as bug fixes implemented in PostgreSQL 16.1 update. For the detailed description, see PostgreSQL 16, and PostgreSQL 16.1 Release Notes.

For the list of extension modules and utilities specific to Postgres Pro Enterprise, as well as the main user-visible core changes over vanilla PostgreSQL, see Section 2. As compared to Postgres Pro Enterprise 15.5.1, the following differences are worth mentioning:

- Implemented the built-in high availability that is achieved by deploying the biha cluster with physical replication, built-in failover, automatic node failure detection, response, and subsequent cluster reconfiguration. Such cluster is configured with one dedicated leader node and several follower nodes, which can be both synchronous and asynchronous, and is managed with the bihactl utility. The new functionality enables protection against server failures and data storage system failures and does not require any additional external cluster software. The cluster variant with two nodes and one referee node will be supported in future releases. SSL/TLS of the `biha` control channel is used experimentally at the moment.
- Added the `vault` schema that allows protecting sensitive data against unauthorized access of malicious users by designating a separate role called security officer who manages access to the schema and its objects.
- Added predefined roles:
  - `pg_create_tablespace`, which allows executing the `CREATE TABLESPACE` command without superuser rights.

  - pg_manage_profiles, which allows executing the CREATE PROFILE, ALTER PROFILE, and DROP PROFILE commands without superuser rights.
- Added system views pg_stats_vacuum_tables, pg_stats_vacuum_indexes and pg_stats_vacuum_database, which show statistics about vacuuming tables, indexes and databases, respectively. These statistics were previously available through pgpro_stats.
- Upgraded aqo to version 2.0, which provides the following major changes and enhancements:
  - The configuration is streamlined. Now aqo behavior mainly depends on three configuration parameters: aqo.enable, aqo.mode and aqo.advanced, which respectively define aqo state, operation mode and whether statistics is isolated per query.
  - The default values of configuration parameters set the recommended basic mode, where statistics is collected for plan nodes, and the collected machine learning data is used to correct the cardinality estimation error for all queries whose plan might contain a certain plan node.
  - aqo can now work with multiple databases independently.
  - Executing the DROP/CREATE EXTENSION command is now sufficient to instantly disable/enable aqo at the database level.
  - Memory consumption is reduced.
- Upgraded pg_probackup to version 2.7.0 Enterprise, which provides new features, optimizations and bug fixes. Notable changes are as follows:
  - Merging of incremental backups is made suitable for use with S3 (Simple Storage Service) by replacing renamed folders with symlinks.
  - The --show-symlinks option is added to the show command to display the links between the original full backups and the resulting merged backups.
  - Merging of backups now occurs without creating temporary local files.
  - Memory usage has been optimized for restoring long sequences of incremental backups of large databases. As a result, the restoration of a database with several thousand tables and about 100 increments consumes up to three times less memory.
  - It is now possible to specify the values of latest and current for the --recovery-target-timeline option. Also, the operation of the --recovery-target option with the value of latest has been fixed.
- Upgraded pg_hint_plan to version 1.6.0.
- Added the pgpro_bfile extension providing a composite type bfile that implements an Oracle-like technique to access an external file.
- Added the pgpro_rp extension that provides resource prioritization by assigning a resource prioritization plan to a particular session, which can slow it down based on the amount of CPU, I/O read, and I/O write resources this session consumes as compared to other sessions.
- Added the sr_plan.auto_tracking configuration parameter that enables sr_plan to normalize and register queries executed using the EXPLAIN command automatically.
- Added the utl_http extension that allows accessing data on the Internet over the HTTP protocol (HTTP/1.0 and HTTP/1.1) by invoking HTTP callouts from SQL and PL/pgSQL.
- Added the utl_smtp extension designed for sending emails over SMTP from PL/pgSQL.
- Added the utl_mail extension designed for managing emails, which includes commonly used email features, such as attachments, CC, and BCC.

> **Note**
>
> In this release, the subscription for which streaming = parallel is specified ignores this setting and does not use parallel apply workers.

> **Warning**
>
> When using the new Postgres Pro Enterprise 16.1.1 features on outdated operating systems, such as ROSA COBALT 7.9, Rosa Enterprise Linux Server 7.3, AlterOS 7 or SLES 12, anticipate issues as these OS include outdated versions of OpenSSL. So consider upgrading to a newer OS version.

E.12.2. Migration to Version 16

You can migrate to Postgres Pro Enterprise 16 from the same or a previous version of PostgreSQL (that is supported by the upgrade method chosen) or Postgres Pro Standard/Postgres Pro Standard Certified and from a previous version of Postgres Pro Enterprise/Postgres Pro Enterprise Certified. The same holds for migration to Postgres Pro Enterprise Certified 16. See Section 18.6 for the methods to upgrade your database cluster. Consult the Postgres Pro Enterprise support team if you experience issues during migration. Backward migration is not supported. Note that migration from Postgres Pro Enterprise to Postgres Pro Enterprise Certified of the same major version (or vice versa) is an update between Postgres Pro compatible versions (see Section 18.6 for more details).

To migrate from PostgreSQL, Postgres Pro Standard, or Postgres Pro Enterprise release based on a previous PostgreSQL major version, make sure to install its latest available minor version and then perform a dump/restore using pg_dumpall or use the pg_upgrade utility.

If you choose to run pg_upgrade, make sure to initialize the new database cluster with compatible parameters. In particular, pay attention to the checksum settings in the cluster you are migrating from. If pg_upgrade creates any SQL files in its current directory, run these files to complete the upgrade.

When migrating from PostgreSQL or Postgres Pro Standard, make sure to pay special attention to implementation specifics of 64-bit transaction IDs. If you have used explicit casts to 32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

> **Note**
>
> To avoid conflicts, do not use the `postgrespro-ent-16` package to install the new Postgres Pro binaries. Use the individual packages instead. In this case, server autostart needs to be enabled manually, if required. For details on the available packages and installation instructions, see Chapter 17.

For other upgrade requirements imposed by vanilla PostgreSQL, see Section E.22.

E.13. Release 16.9

Release date: 2025-05-08

This release contains a variety of fixes from 16.8. For information about new features in major release 16, see Section E.22.

E.13.1. Migration to Version 16.9

A dump/restore is not required for those running 16.X.

However, if you have any self-referential foreign key constraints on partitioned tables, it may be necessary to recreate those constraints to ensure that they are being enforced correctly. See the second changelog entry below.

Also, if you have any BRIN bloom indexes, it may be advisable to reindex them after updating. See the third changelog entry below.

Also, if you are upgrading from a version earlier than 16.5, see Section E.17.

E.13.2. Changes

- Avoid one-byte buffer overread when examining invalidly-encoded strings that are claimed to be in GB18030 encoding (Noah Misch, Andres Freund)

  While unlikely, a SIGSEGV crash could occur if an incomplete multibyte character appeared at the end of memory. This was possible both in the server and in libpq-using applications. (CVE-2025-4207)

- Handle self-referential foreign keys on partitioned tables correctly (Álvaro Herrera)

  Creating or attaching partitions failed to make the required catalog entries for a foreign-key constraint, if the table referenced by the constraint was the same partitioned table. This resulted in failure to enforce the constraint fully.

  To fix this, you should drop and recreate any self-referential foreign keys on partitioned tables, if partitions have been created or attached since the constraint was created. Bear in mind that violating rows might already be present, in which case recreating the constraint will fail, and you'll need to fix up those rows before trying again.

- Avoid data loss when merging compressed BRIN summaries in `brin_bloom_union()` (Tomas Vondra)

  The code failed to account for decompression results not being identical to the input objects, which would result in failure to add some of the data to the merged summary, leading to missed rows in index searches.

  This mistake was present back to v14 where BRIN bloom indexes were introduced, but this code path was only rarely reached then. It's substantially more likely to be hit in v17 because parallel index builds now use the code.

- Fix unexpected “attribute has wrong type” errors in `UPDATE`, `DELETE`, and `MERGE` queries that use whole-row table references to views or functions in `FROM` (Tom Lane)

- Fix `MERGE` into a partitioned table with `DO NOTHING` actions (Tender Wang)

  Some cases failed with “unknown action in MERGE WHEN clause” errors.

- Prevent failure in `INSERT` commands when the table has a `GENERATED` column of a domain data type and the domain's constraints disallow null values (Jian He)

  Constraint failure was reported even if the generation expression produced a perfectly okay result.

- Correctly process references to outer CTE names that appear within a `WITH` clause attached to an `INSERT`/`UPDATE`/`DELETE`/`MERGE` command that's inside `WITH` (Tom Lane)

  The parser failed to detect disallowed recursion cases, nor did it account for such references when sorting CTEs into a usable order.

- Don't try to parallelize `array_agg()` when the argument is of an anonymous record type (Richard Guo, Tom Lane)

  The protocol for communicating with parallel workers doesn't support identifying the concrete record type that a worker is returning.

- Fix `ARRAY(`*`subquery`*`)` and `ARRAY[`*`expression`*`, ...]` constructs to produce sane results when the input is of type `int2vector` or `oidvector` (Tom Lane)

  This patch restores the behavior that existed before PostgreSQL 9.5: the result is of type `int2vector[]` or `oidvector[]`.

- Fix possible erroneous reports of invalid affixes while parsing Ispell dictionaries (Jacob Brazeal)

- Fix `ALTER TABLE ADD COLUMN` to correctly handle the case of a domain type that has a default (Jian He, Tom Lane, Tender Wang)

  If a domain type has a default, adding a column of that type (without any explicit `DEFAULT` clause) failed to install the domain's default value in existing rows, instead leaving the new column null.

- Repair misbehavior when there are duplicate column names in a foreign key constraint's `ON DELETE SET DEFAULT` or `SET NULL` action (Tom Lane)

- Improve the error message for disallowed attempts to alter the properties of a foreign key constraint (Álvaro Herrera)

- Avoid error when resetting the `relhassubclass` flag of a temporary table that's marked `ON COMMIT DELETE ROWS` (Noah Misch)

- Add missing deparsing of the `INDENT` option of `XMLSERIALIZE()` (Jim Jones)

  Previously, views or rules using `XMLSERIALIZE(... INDENT)` were dumped without the `INDENT` clause, causing incorrect results after restore.

- Avoid premature evaluation of the arguments of an aggregate function that has both `FILTER` and `ORDER BY` (or `DISTINCT`) options (David Rowley)

  If there is `ORDER BY` or `DISTINCT`, we consider pre-sorting the aggregate input values rather than doing the sort within the Agg plan node. But this is problematic if the aggregate inputs include expressions that could fail (for example, a division where some of the input divisors could be zero) and there is a `FILTER` clause that's meant to prevent such failures. Pre-sorting would push the expression evaluations to before the `FILTER` test, allowing the failures to happen anyway. Avoid this by not pre-sorting if there's a `FILTER` and the input expressions are anything more complex than a simple Var or Const.

- Fix planner's failure to identify more than one hashable ScalarArrayOpExpr subexpression within a top-level expression (David Geier)

  This resulted in unnecessarily-inefficient execution of any additional subexpressions that could have been processed with a hash table (that is, `IN`, `NOT IN`, or `= ANY` clauses with all-constant right-hand sides).

- Disable “skip fetch” optimization in bitmap heap scan (Matthias van de Meent)

  It turns out that this optimization can result in returning dead tuples when a concurrent vacuum marks a page all-visible.

- Fix performance issues in GIN index search startup when there are many search keys (Tom Lane, Vinod Sridharan)

  An indexable clause with many keys (for example, `jsonbcol ?| array[...]` with tens of thousands of array elements) took $O(N^2)$ time to start up, and was uncancelable for that interval too.

- Detect missing support procedures in a BRIN index operator class, and report an error instead of crashing (Álvaro Herrera)

- Respond to interrupts (such as query cancel) while waiting for asynchronous subplans of an Append plan node (Heikki Linnakangas)

  Previously, nothing would happen until one of the subplans becomes ready.

- Report the I/O statistics of active WAL senders more frequently (Bertrand Drouvot)

  Previously, the `pg_stat_io` view failed to accumulate I/O performed by a WAL sender until that process exited. Now such I/O will be reported after at most one second's delay.

- Fix race condition in handling of `synchronous_standby_names` immediately after startup (Melnikov Maksim, Michael Paquier)

For a short period after system startup, backends might fail to wait for synchronous commit even though `synchronous_standby_names` is enabled.

- Avoid infinite loop if `scram_iterations` is set to INT_MAX (Kevin K Biju)
- Avoid possible crashes due to double transformation of `json_array()`'s subquery (Tom Lane)
- Fix `pg_strtof()` to not crash with null endptr (Alexander Lakhin, Tom Lane)
- Fix crash after out-of-memory in certain GUC assignments (Daniel Gustafsson)
- Avoid crash when a Snowball stemmer encounters an out-of-memory condition (Maksim Korotkov)
- Disallow copying of invalidated replication slots (Shlok Kyal)

  This prevents trouble when the invalid slot points to WAL that's already been removed.
- Disallow restoring logical replication slots on standby servers that are not in hot-standby mode (Masahiko Sawada)

  This prevents a scenario where the slot could remain valid after promotion even if `wal_level` is too low.
- Prevent over-advancement of catalog xmin in “fast forward” mode of logical decoding (Zhijie Hou)

  This mistake could allow deleted catalog entries to be vacuumed away even though they were still potentially needed by the WAL-reading process.
- Avoid data loss when DDL operations that don't take a strong lock affect tables that are being logically replicated (Shlok Kyal, Hayato Kuroda)

  The catalog changes caused by the DDL command were not reflected into WAL-decoding processes, allowing them to decode subsequent changes using stale catalog data, probably resulting in data corruption.
- Prevent incorrect reset of replication origin when an apply worker encounters an error but the error is caught and does not result in worker exit (Hayato Kuroda)

  This mistake could allow duplicate data to be applied.
- Avoid duplicate snapshot creation in logical replication index lookups (Heikki Linnakangas)
- Improve detection of mixed-origin subscriptions (Hou Zhijie, Shlok Kyal)

  Subscription creation gives a warning if a subscribed-to table is also being followed through other publications, since that could cause duplicate data to be received. This change improves that logic to also detect cases where a partition parent or child table is the one being followed through another publication.
- Fix wrong checkpoint details in error message about incorrect recovery timeline choice (David Steele)

  If the requested recovery timeline is not reachable, the reported checkpoint and timeline should be the values read from the backup_label, if there is one. This message previously reported values from the control file, which is correct when recovering from the control file without a backup_label, but not when there is a backup_label.
- Remove incorrect assertion in `pgstat_report_stat()` (Michael Paquier)
- Fix overly-strict assertion in `gistFindCorrectParent()` (Heikki Linnakangas)
- Fix rare assertion failure in standby servers when the primary is restarted (Heikki Linnakangas)
- In PL/pgSQL, avoid “unexpected plan node type” error when a scrollable cursor is defined on a simple `SELECT` *`expression`* query (Andrei Lepikhov)

- Don't try to drop individual index partitions in pg_dump's `--clean` mode (Jian He)

  The server rejects such `DROP` commands. That has no real consequences, since the partitions will go away anyway in the subsequent `DROP`s of either their parent tables or their partitioned index. However, the error reported for the attempted drop causes problems when restoring in `--single-transaction` mode.

- In pg_dumpall, avoid emitting invalid role `GRANT` commands if `pg_auth_members` contains invalid role OIDs (Tom Lane)

  Instead, print a warning and skip the entry. This copes better with catalog corruption that has been seen to occur in back branches as a result of race conditions between `GRANT` and `DROP ROLE`.

- In pg_amcheck and pg_upgrade, use the correct function to free allocations made by libpq (Michael Paquier, Ranier Vilela)

  These oversights could result in crashes in certain Windows build configurations, such as a debug build of libpq used by a non-debug build of the calling application.

- Allow `contrib/dblink` queries to be interrupted by query cancel (Noah Misch)

  This change back-patches a v17-era fix. It prevents possible hangs in `CREATE DATABASE` and `DROP DATABASE` due to failure to detect deadlocks.

- Avoid crashing with corrupt input data in `contrib/pageinspect`'s `heap_page_items()` (Dmitry Kovalenko)

- Prevent assertion failure in `contrib/pg_freespacemap`'s `pg_freespacemap()` (Tender Wang)

  Applying `pg_freespacemap()` to a relation lacking storage (such as a view) caused an assertion failure, although there was no ill effect in non-assert builds. Add an error check to reject that case.

- Fix build failure on macOS 15.4 (Tom Lane, Peter Eisentraut)

  This macOS update broke our configuration probe for `strchrnul()`.

- Update time zone data files to tzdata release 2025b for DST law changes in Chile, plus historical corrections for Iran (Tom Lane)

  There is a new time zone America/Coyhaique for Chile's Aysén Region, to account for it changing to UTC-03 year-round and thus diverging from America/Santiago.

E.14. Release 16.8

Release date: 2025-02-20

This release contains a few fixes from 16.7. For information about new features in major release 16, see Section E.22.

E.14.1. Migration to Version 16.8

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.5, see Section E.17.

E.14.2. Changes

- Improve behavior of libpq's quoting functions (Andres Freund, Tom Lane)

  The changes made for CVE-2025-1094 had one serious oversight: `PQescapeLiteral()` and `PQescapeIdentifier()` failed to honor their string length parameter, instead always reading to the input string's trailing null. This resulted in including unwanted text in the output, if the caller in-

tended to truncate the string via the length parameter. With very bad luck it could cause a crash due to reading off the end of memory.

In addition, modify all these quoting functions so that when invalid encoding is detected, an invalid sequence is substituted for just the first byte of the presumed character, not all of it. This reduces the risk of problems if a calling application performs additional processing on the quoted string.

- Fix meson build system to correctly detect availability of the `bsd_auth.h` system header (Nazir Bilal Yavuz)

E.15. Release 16.7

Release date: 2025-02-13

This release contains a variety of fixes from 16.6. For information about new features in major release 16, see Section E.22.

E.15.1. Migration to Version 16.7

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.5, see Section E.17.

E.15.2. Changes

- Harden `PQescapeString` and allied functions against invalidly-encoded input strings (Andres Freund, Noah Misch)

  Data-quoting functions supplied by libpq now fully check the encoding validity of their input. If invalid characters are detected, they report an error if possible. For the ones that lack an error return convention, the output string is adjusted to ensure that the server will report invalid encoding and no intervening processing will be fooled by bytes that might happen to match single quote, backslash, etc.

  The purpose of this change is to guard against SQL-injection attacks that are possible if one of these functions is used to quote crafted input. There is no hazard when the resulting string is sent directly to a PostgreSQL server (which would check its encoding anyway), but there is a risk when it is passed through psql or other client-side code. Historically such code has not carefully vetted encoding, and in many cases it's not clear what it should do if it did detect such a problem.

  This fix is effective only if the data-quoting function, the server, and any intermediate processing agree on the character encoding that's being used. Applications that insert untrusted input into SQL commands should take special care to ensure that that's true.

  Applications and drivers that quote untrusted input without using these libpq functions may be at risk of similar problems. They should first confirm the data is valid in the encoding expected by the server.

  The PostgreSQL Project thanks Stephen Fewer for reporting this problem. (CVE-2025-1094)

- Exclude parallel workers from connection privilege checks and limits (Tom Lane)

  Do not check `datallowconn`, `rolcanlogin`, and `ACL_CONNECT` privileges when starting a parallel worker, instead assuming that it's enough for the leader process to have passed similar checks originally. This avoids, for example, unexpected failures of parallelized queries when the leader is running as a role that lacks login privilege. In the same vein, enforce `ReservedConnections`, `datconnlimit`, and `rolconnlimit` limits only against regular backends, and count only regular backends while checking if the limits were already reached. Those limits are meant to prevent excessive consumption of process slots for regular backends --- but parallel workers and other special processes have their own pools of process slots with their own limit checks.

- Fix possible re-use of stale results in window aggregates (David Rowley)

A window aggregate with a “run condition” optimization and a pass-by-reference result type might incorrectly return the result from the previous partition instead of performing a fresh calculation.

- Keep `TransactionXmin` in sync with `MyProc->xmin` (Heikki Linnakangas)

  This oversight could permit a process to try to access data that had already been vacuumed away. One known consequence is transient “could not access status of transaction” errors.

- Fix race condition that could cause failure to add a newly-inserted catalog entry to a catalog cache list (Heikki Linnakangas)

  This could result, for example, in failure to use a newly-created function within an existing session.

- Prevent possible catalog corruption when a system catalog is vacuumed concurrently with an update (Noah Misch)

- Fix data corruption when relation truncation fails (Thomas Munro)

  The filesystem calls needed to perform relation truncation could fail, leaving inconsistent state on disk (for example, effectively reviving deleted data). We can't really prevent that, but we can recover by dint of making such failures into PANICs, so that consistency is restored by replaying from WAL up to just before the attempted truncation. This isn't a hugely desirable behavior, but such failures are rare enough that it seems an acceptable solution.

- Prevent checkpoints from starting during relation truncation (Robert Haas)

  This avoids a race condition wherein the modified file might not get fsync'd before completing the checkpoint, creating a risk of data corruption if the operating system crashes soon after.

- Avoid possibly losing an update of `pg_database.datfrozenxid` when `VACUUM` runs concurrently with a `REASSIGN OWNED` that changes that database's owner (Kirill Reshke)

- Fix incorrect `tg_updatedcols` values passed to `AFTER UPDATE` triggers (Tom Lane)

  In some cases the `tg_updatedcols` bitmap could describe the set of columns updated by an earlier command in the same transaction, fooling the trigger into doing the wrong thing.

  Also, prevent memory bloat caused by making too many copies of the `tg_updatedcols` bitmap.

- Fix detach of a partition that has its own foreign-key constraint referencing a partitioned table (Amul Sul)

  In common cases, foreign keys are defined on a partitioned table's top level; but if instead one is defined on a partition and references a partitioned table, and the referencing partition is detached, the relevant `pg_constraint` entries were updated incorrectly. This led to errors like “could not find ON INSERT check triggers of foreign key constraint”.

- Fix mis-processing of `to_timestamp`'s `FF`*n* format codes (Tom Lane)

  An integer format code immediately preceding `FF`*n* would consume all available digits, leaving none for `FF`*n*.

- When deparsing an `XMLTABLE()` expression, ensure that XML namespace names are double-quoted when necessary (Dean Rasheed)

- Include the `ldapscheme` option in `pg_hba_file_rules()` output (Laurenz Albe)

- Don't merge `UNION` operations if their column collations aren't consistent (Tom Lane)

  Previously we ignored collations when deciding if it's safe to merge `UNION` steps into a single N-way `UNION` operation. This was arguably valid before the introduction of nondeterministic collations, but it's not anymore, since the collation in use can affect the definition of uniqueness.

- Prevent “wrong varnullingrels” planner errors after pulling up a subquery that's underneath an outer join (Tom Lane)

- Ignore nulling-relation marker bits when looking up statistics (Richard Guo)

  This oversight could lead to failure to use relevant statistics about expressions, or to “corrupt MVNDistinct entry” errors.

- Fix missed expression processing for partition pruning steps (Tom Lane)

  This oversight could lead to “unrecognized node type” errors, and perhaps other problems, in queries accessing partitioned tables.

- Allow dshash tables to grow past 1GB (Matthias van de Meent)

  This avoids errors like “invalid DSA memory alloc request size”. The case can occur for example in transactions that process several million tables.

- Avoid possible integer overflow in `bringetbitmap()` (James Hunter, Evgeniy Gorbanyov)

  Since the result is only used for statistical purposes, the effects of this error were mostly cosmetic.

- Ensure that an already-set process latch doesn't prevent the postmaster from noticing socket events (Thomas Munro)

  An extremely heavy workload of backends launching workers and workers exiting could prevent the postmaster from responding to incoming client connections in a timely fashion.

- Prevent streaming standby servers from looping infinitely when reading a WAL record that crosses pages (Kyotaro Horiguchi, Alexander Kukushkin)

  This would happen when the record's continuation is on a page that needs to be read from a different WAL source.

- Fix unintended promotion of FATAL errors to PANIC during early process startup (Noah Misch)

  This fixes some unlikely cases that would result in “PANIC: proc_exit() called in child process”.

- Fix cases where an operator family member operator or support procedure could become a dangling reference (Tom Lane)

  In some cases a data type could be dropped while references to its OID still remain in `pg_amop` or `pg_amproc`. While that caused no immediate issues, an attempt to drop the owning operator family would fail, and pg_dump would produce bogus output when dumping the operator family. This fix causes creation and modification of operator families/classes to add needed dependency entries so that dropping a data type will also drop any dependent operator family elements. That does not help vulnerable pre-existing operator families, though, so a band-aid has also been added to `DROP OPERATOR FAMILY` to prevent failure when dropping a family that has dangling members.

- Fix multiple memory leaks in logical decoding output (Vignesh C, Masahiko Sawada, Boyu Yang)

- Fix small memory leak when updating the `application_name` or `cluster_name` settings (Tofig Aliev)

- Avoid integer overflow while testing `wal_skip_threshold` condition (Tom Lane)

  A transaction that created a very large relation could mistakenly decide to ensure durability by copying the relation into WAL instead of fsync'ing it, thereby negating the point of `wal_skip_threshold`. (This only matters when `wal_level` is set to `minimal`, else a WAL copy is required anyway.)

- Fix unsafe order of operations during cache lookups (Noah Misch)

  The only known consequence was a usually-harmless “you don't own a lock of type ExclusiveLock” warning during `GRANT TABLESPACE`.

- Fix possible “failed to resolve name” failures when using JIT on older ARM platforms (Thomas Munro)

This could occur as a consequence of inconsistency about the default setting of `-moutline-atomics` between gcc and clang. At least Debian and Ubuntu are known to ship gcc and clang compilers that target armv8-a but differ on the use of outline atomics by default.

- Fix assertion failure in `WITH RECURSIVE ... UNION` queries (David Rowley)
- Avoid assertion failure in rule deparsing if a set operation leaf query contains set operations (Man Zeng, Tom Lane)
- Avoid edge-case assertion failure in parallel query startup (Tom Lane)
- Fix assertion failure at shutdown when writing out the statistics file (Michael Paquier)
- In `NULLIF()`, avoid passing a read-write expanded object pointer to the data type's equality function (Tom Lane)

  The equality function could modify or delete the object if it's given a read-write pointer, which would be bad if we decide to return it as the `NULLIF()` result. There is probably no problem with any built-in equality function, but it's easy to demonstrate a failure with one coded in PL/pgSQL.
- Ensure that expression preprocessing is applied to a default null value in `INSERT` (Tom Lane)

  If the target column is of a domain type, the planner must insert a coerce-to-domain step not just a null constant, and this expression missed going through some required processing steps. There is no known consequence with domains based on core data types, but in theory an error could occur with domains based on extension types.
- Repair memory leaks in PL/Python (Mat Arye, Tom Lane)

  Repeated use of `PLyPlan.execute` or `plpy.cursor` resulted in memory leakage for the duration of the calling PL/Python function.
- Fix PL/Tcl to compile with Tcl 9 (Peter Eisentraut)
- In the ecpg preprocessor, fix possible misprocessing of cursors that reference out-of-scope variables (Tom Lane)
- In ecpg, fix compile-time warnings about unsupported use of `COPY ... FROM STDIN` (Ryo Kanbayashi)

  Previously, the intended warning was not issued due to a typo.
- Fix psql to safely handle file path names that are encoded in SJIS (Tom Lane)

  Some two-byte characters in SJIS have a second byte that is equal to ASCII backslash (`\`). These characters were corrupted by path name normalization, preventing access to files whose names include such characters.
- Fix use of wrong version of `pqsignal()` in pgbench and psql (Fujii Masao, Tom Lane)

  This error could lead to misbehavior when using the `-T` option in pgbench or the `\watch` command in psql, due to interrupted system calls not being resumed as expected.
- Fix misexecution of some nested `\if` constructs in pgbench (Michail Nikolaev)

  An `\if` command appearing within a false (not-being-executed) `\if` branch was incorrectly treated the same as `\elif`.
- In pgbench, fix possible misdisplay of progress messages during table initialization (Yushi Ogiwara, Tatsuo Ishii, Fujii Masao)
- Make pg_controldata more robust against corrupted `pg_control` files (Ilyasov Ian, Anton Voloshin)

  Since pg_controldata will attempt to print the contents of `pg_control` even if the CRC check fails, it must take care not to misbehave for invalid field values. This patch fixes some issues triggered by invalid timestamps and apparently-negative WAL segment sizes.

- Fix possible crash in pg_dump with identity sequences attached to tables that are extension members (Tom Lane)
- Fix memory leak in pg_restore with zstd-compressed data (Tom Lane)

  The leak was per-decompression-operation, so would be most noticeable with a dump containing many tables or large objects.
- Fix pg_basebackup to correctly handle `pg_wal.tar` files exceeding 2GB on Windows (Davinder Singh, Thomas Munro)
- Use SQL-standard function bodies in the declarations of `contrib/earthdistance`'s SQL-language functions (Tom Lane, Ronan Dunklau)

  This change allows their references to `contrib/cube` to be resolved during extension creation, reducing the risk of search-path-based failures and possible attacks.

  In particular, this restores their usability in contexts like generated columns, for which PostgreSQL v17 restricts the search path on security grounds. We have received reports of databases failing to be upgraded to v17 because of that. This patch has been included in v16 to provide a workaround: updating the `earthdistance` extension to this version beforehand should allow an upgrade to succeed.
- Update configuration probes that determine the compiler switches needed to access ARM CRC instructions (Tom Lane)

  On ARM platforms where the baseline CPU target lacks CRC instructions, we need to supply a `-march` switch to persuade the compiler to compile such instructions. Recent versions of gcc reject the value we were trying, leading to silently falling back to software CRC.
- Fix meson build system to support old OpenSSL libraries on Windows (Darek Slusarczyk)

  Add support for the legacy library names `ssleay32` and `libeay32`.
- In Windows builds using meson, ensure all libcommon and libpgport functions are exported (Vladlen Popolitov, Heikki Linnakangas)

  This fixes “unresolved external symbol” build errors for extensions.
- Fix meson configuration process to correctly detect OSSP's `uuid.h` header file under MSVC (Andrew Dunstan)
- When building with meson, install `pgevent` in *`pkglibdir`* not *`bindir`* (Peter Eisentraut)

  This matches the behavior of the make-based build system and the old MSVC build system.
- When building with meson, install `sepgsql.sql` under `share/contrib/` not `share/extension/` (Peter Eisentraut)

  This matches what the make-based build system does.
- Update time zone data files to tzdata release 2025a for DST law changes in Paraguay, plus historical corrections for the Philippines (Tom Lane)

E.16. Release 16.6

Release date: 2024-11-21

This release contains a few fixes from 16.5. For information about new features in major release 16, see Section E.22.

E.16.1. Migration to Version 16.6

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.5, see Section E.17.

E.16.2. Changes

- Repair ABI break for extensions that work with struct `ResultRelInfo` (Tom Lane)

  Last week's minor releases unintentionally broke binary compatibility with timescaledb and several other extensions. Restore the affected structure to its previous size, so that such extensions need not be rebuilt.

- Restore functionality of `ALTER {ROLE|DATABASE} SET role` (Tom Lane, Noah Misch)

  The fix for CVE-2024-10978 accidentally caused settings for `role` to not be applied if they come from non-interactive sources, including previous `ALTER {ROLE|DATABASE}` commands and the `PGOPTIONS` environment variable.

- Fix cases where a logical replication slot's `restart_lsn` could go backwards (Masahiko Sawada)

  Previously, restarting logical replication could sometimes cause the slot's restart point to be recomputed as an older value than had previously been advertised in `pg_replication_slots`. This is bad, since for example WAL files might have been removed on the basis of the later `restart_lsn` value, in which case replication would fail to restart.

- Avoid deleting still-needed WAL files during pg_rewind (Polina Bungina, Alexander Kukushkin)

  Previously, in unlucky cases, it was possible for pg_rewind to remove important WAL files from the rewound demoted primary. In particular this happens if those files have been marked for archival (i.e., their `.ready` files were created) but not yet archived. Then the newly promoted node no longer has such files because of them having been recycled, but likely they are needed for recovery in the demoted node. If pg_rewind removes them, recovery is not possible anymore.

- Fix race conditions associated with dropping shared statistics entries (Kyotaro Horiguchi, Michael Paquier)

  These bugs could lead to loss of statistics data, assertion failures, or “can only drop stats once” errors.

- Count index scans in `contrib/bloom` indexes in the statistics views, such as the `pg_stat_user_indexes.idx_scan` counter (Masahiro Ikeda)

- Fix crash when checking to see if an index's opclass options have changed (Alexander Korotkov)

  Some forms of `ALTER TABLE` would fail if the table has an index with non-default operator class options.

- Avoid assertion failure caused by disconnected NFA sub-graphs in regular expression parsing (Tom Lane)

  This bug does not appear to have any visible consequences in non-assert builds.

E.17. Release 16.5

Release date: 2024-11-14

This release contains a variety of fixes from 16.4. For information about new features in major release 16, see Section E.22.

E.17.1. Migration to Version 16.5

A dump/restore is not required for those running 16.X.

However, if you have ever detached a partition from a partitioned table that has a foreign-key reference to another partitioned table, and not dropped the former partition, then you may have catalog and/or data corruption to repair, as detailed in the fifth changelog entry below.

Also, if you are upgrading from a version earlier than 16.3, see Section E.19.

E.17.2. Changes

- Ensure cached plans are marked as dependent on the calling role when RLS applies to a non-top-level table reference (Nathan Bossart)

  If a CTE, subquery, sublink, security invoker view, or coercion projection in a query references a table with row-level security policies, we neglected to mark the resulting plan as potentially dependent on which role is executing it. This could lead to later query executions in the same session using the wrong plan, and then returning or hiding rows that should have been hidden or returned instead.

  The PostgreSQL Project thanks Wolfgang Walther for reporting this problem. (CVE-2024-10976)

- Make libpq discard error messages received during SSL or GSS protocol negotiation (Jacob Champion)

  An error message received before encryption negotiation is completed might have been injected by a man-in-the-middle, rather than being real server output. Reporting it opens the door to various security hazards; for example, the message might spoof a query result that a careless user could mistake for correct output. The best answer seems to be to discard such data and rely only on libpq's own report of the connection failure.

  The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2024-10977)

- Fix unintended interactions between `SET SESSION AUTHORIZATION` and `SET ROLE` (Tom Lane)

  The SQL standard mandates that `SET SESSION AUTHORIZATION` have a side-effect of doing `SET ROLE NONE`. Our implementation of that was flawed, creating more interaction between the two settings than intended. Notably, rolling back a transaction that had done `SET SESSION AUTHORIZATION` would revert `ROLE` to `NONE` even if that had not been the previous state, so that the effective user ID might now be different from what it had been before the transaction. Transiently setting `session_authorization` in a function `SET` clause had a similar effect. A related bug was that if a parallel worker inspected `current_setting('role')`, it saw `none` even when it should see something else.

  The PostgreSQL Project thanks Tom Lane for reporting this problem. (CVE-2024-10978)

- Prevent trusted PL/Perl code from changing environment variables (Andrew Dunstan, Noah Misch)

  The ability to manipulate process environment variables such as `PATH` gives an attacker opportunities to execute arbitrary code. Therefore, “trusted” PLs must not offer the ability to do that. To fix `plperl`, replace `%ENV` with a tied hash that rejects any modification attempt with a warning. Untrusted `plperlu` retains the ability to change the environment.

  The PostgreSQL Project thanks Coby Abrams for reporting this problem. (CVE-2024-10979)

- Fix updates of catalog state for foreign-key constraints when attaching or detaching table partitions (Jehan-Guillaume de Rorthais, Tender Wang, Álvaro Herrera)

  If the referenced table is partitioned, then different catalog entries are needed for a referencing table that is stand-alone versus one that is a partition. `ATTACH/DETACH PARTITION` commands failed to perform this conversion correctly. In particular, after `DETACH` the now stand-alone table would be missing foreign-key enforcement triggers, which could result in the table later containing rows that fail the foreign-key constraint. A subsequent re-`ATTACH` could fail with surprising errors, too.

  The way to fix this is to do `ALTER TABLE DROP CONSTRAINT` on the now stand-alone table for each faulty constraint, and then re-add the constraint. If re-adding the constraint fails, then some erroneous data has crept in. You will need to manually re-establish consistency between the referencing and referenced tables, then re-add the constraint.

This query can be used to identify broken constraints and construct the commands needed to recreate them:

```
SELECT conrelid::pg_catalog.regclass AS "constrained table",
       conname AS constraint,
       confrelid::pg_catalog.regclass AS "references",
       pg_catalog.format('ALTER TABLE %s DROP CONSTRAINT %I;',
                         conrelid::pg_catalog.regclass, conname) AS "drop",
       pg_catalog.format('ALTER TABLE %s ADD CONSTRAINT %I %s;',
                         conrelid::pg_catalog.regclass, conname,
                         pg_catalog.pg_get_constraintdef(oid)) AS "add"
FROM pg_catalog.pg_constraint c
WHERE contype = 'f' AND conparentid = 0 AND
   (SELECT count(*) FROM pg_catalog.pg_constraint c2
    WHERE c2.conparentid = c.oid) <>
   (SELECT count(*) FROM pg_catalog.pg_inherits i
    WHERE (i.inhparent = c.conrelid OR i.inhparent = c.confrelid) AND
      EXISTS (SELECT 1 FROM pg_catalog.pg_partitioned_table
              WHERE partrelid = i.inhparent));
```

Since it is possible that one or more of the `ADD CONSTRAINT` steps will fail, you should save the query's output in a file and then attempt to perform each step.

- Avoid possible crashes and “could not open relation” errors in queries on a partitioned table occurring concurrently with a `DETACH CONCURRENTLY` and immediate drop of a partition (Álvaro Herrera, Kuntal Gosh)
- Disallow `ALTER TABLE ATTACH PARTITION` if the table to be attached has a foreign key referencing the partitioned table (Álvaro Herrera)

  This arrangement is not supported, and other ways of creating it already fail.
- Don't use partitionwise joins or grouping if the query's collation for the key column doesn't match the partition key's collation (Jian He, Webbo Han)

  Such plans could produce incorrect results.
- Fix possible “could not find pathkey item to sort” error when the output of a `UNION ALL` member query needs to be sorted, and the sort column is an expression (Andrei Lepikhov, Tom Lane)
- Fix performance regressions involving flattening of subqueries underneath outer joins that are later reduced to plain joins (Tom Lane)

  v16 failed to optimize some queries as well as prior versions had, because of overoptimistic simplification of query-pullup logic.
- Allow cancellation of the second stage of index build for large hash indexes (Pavel Borisov)
- Fix assertion failure or confusing error message for `COPY (`*`query`*`) TO ...`, when the *`query`* is rewritten by a `DO INSTEAD NOTIFY` rule (Tender Wang, Tom Lane)
- Fix server crash when a `json_objectagg()` call contains a volatile function (Amit Langote)
- Fix checking of key uniqueness in JSON object constructors (Junwang Zhao, Tomas Vondra)

  When building an object larger than a kilobyte, it was possible to accept invalid input that includes duplicate object keys, or to falsely report that duplicate keys are present.
- Fix detection of skewed data during parallel hash join (Thomas Munro)

  After repartitioning the inner side of a hash join because one partition has accumulated too many tuples, we check to see if all the partition's tuples went into the same child partition, which suggests that they all have the same hash value and further repartitioning cannot improve matters. This check malfunctioned in some cases, allowing repeated futile repartitioning which would eventually end in a resource-exhaustion error.

- Disallow locale names containing non-ASCII characters (Thomas Munro)

  This is only an issue on Windows, as such locale names are not used elsewhere. They are problematic because it's quite unclear what encoding such names are represented in (since the locale itself defines the encoding to use). In recent PostgreSQL releases, an abort in the Windows runtime library could occur because of confusion about that.

  Anyone who encounters the new error message should either create a new duplicated locale with an ASCII-only name using Windows Locale Builder, or consider using BCP 47-compliant locale names like `tr-TR`.

- Fix race condition in committing a serializable transaction (Heikki Linnakangas)

  Mis-processing of a recently committed transaction could lead to an assertion failure or a “could not access status of transaction” error.

- Fix race condition in `COMMIT PREPARED` that resulted in orphaned 2PC files (wuchengwen)

  A concurrent `PREPARE TRANSACTION` could cause `COMMIT PREPARED` to not remove the on-disk two-phase state file for the completed transaction. There was no immediate ill effect, but a subsequent crash-and-recovery could fail with “could not access status of transaction”, requiring manual removal of the orphaned file to restore service.

- Avoid invalid memory accesses after skipping an invalid toast index during `VACUUM FULL` (Tender Wang)

  A list tracking yet-to-be-rebuilt indexes was not properly updated in this code path, risking assertion failures or crashes later on.

- Fix ways in which an “in place” catalog update could be lost (Noah Misch)

  Normal row updates write a new version of the row to preserve rollback-ability of the transaction. However, certain system catalog updates are intentionally non-transactional and are done with an in-place update of the row. These patches fix race conditions that could cause the effects of an in-place update to be lost. As an example, it was possible to forget having set `pg_class.relhasindex` to true, preventing updates of the new index and thus causing index corruption.

- Reset catalog caches at end of recovery (Noah Misch)

  This prevents scenarios wherein an in-place catalog update could be lost due to using stale data from a catalog cache.

- Avoid using parallel query while holding off interrupts (Francesco Degrassi, Noah Misch, Tom Lane)

  This situation cannot arise normally, but it can be reached with test scenarios such as using a SQL-language function as B-tree support (which would be far too slow for production usage). If it did occur it would result in an indefinite wait.

- Report the active query ID for statistics purposes at the start of processing of Bind and Execute protocol messages (Sami Imseih)

  This allows more of the work done in extended query protocol to be attributed to the correct query.

- Guard against stack overflow in libxml2 with too-deeply-nested XML input (Tom Lane, with hat tip to Nick Wellnhofer)

  Use `xmlXPathCtxtCompile()` rather than `xmlXPathCompile()`, because the latter fails to protect itself against recursion-to-stack-overflow in libxml2 releases before 2.13.4.

- Fix some whitespace issues in the result of `XMLSERIALIZE(... INDENT)` (Jim Jones)

  Fix failure to indent nodes separated by whitespace, and ensure that a trailing newline is not added.

- Do not ignore a concurrent `REINDEX CONCURRENTLY` that is working on an index with predicates or expressions (Michail Nikolaev)

  Normally, `REINDEX CONCURRENTLY` does not need to wait for other `REINDEX CONCURRENTLY` operations on other tables. However, this optimization is not applied if the other `REINDEX CONCURRENTLY` is processing an index with predicates or expressions, on the chance that such expressions contain user-defined code that accesses other tables. Careless coding created a race condition such that that rule was not applied uniformly, possibly allowing inconsistent behavior.

- Fix mis-deparsing of `ORDER BY` lists when there is a name conflict (Tom Lane)

  If an `ORDER BY` item in `SELECT` is a bare identifier, the parser first seeks it as an output column name of the `SELECT`, for SQL92 compatibility. However, ruleutils.c expects the SQL99 interpretation where such a name is an input column name. So it was possible to produce an incorrect display of a view in the (rather ill-advised) case where some other column is renamed in the `SELECT` output list to match an input column used in `ORDER BY`. Fix by table-qualifying such names in the dumped view text.

- Fix “failed to find plan for subquery/CTE” errors in `EXPLAIN` (Richard Guo, Tom Lane)

  This case arose while trying to print references to fields of a RECORD-type output of a subquery when the subquery has been optimized out of the plan altogether (which is possible at least in the case that it has a constant-false `WHERE` condition). Nothing remains in the plan to identify the original field names, so fall back to printing *`fN`* for the *`N`*'th record column. (That's actually the right thing anyway, if the record output arose from a `ROW()` constructor.)

- Disallow a `USING` clause when altering the type of a generated column (Peter Eisentraut)

  A generated column already has an expression specifying the column contents, so including `USING` doesn't make sense.

- Ignore not-yet-defined Portals in the `pg_cursors` view (Tom Lane)

  It is possible for user-defined code that inspects this view to be called while a new cursor is being set up, and if that happens a null pointer dereference would ensue. Avoid the problem by defining the view to exclude incompletely-set-up cursors.

- Fix incorrect output of the `pg_stat_io` view on 32-bit machines (Bertrand Drouvot)

  The `stats_reset` timestamp column contained garbage on such hardware.

- Prevent mis-encoding of “trailing junk after numeric literal” error messages (Karina Litskevich)

  We do not allow identifiers to appear immediately following numeric literals (there must be some whitespace between). If a multibyte character immediately followed a numeric literal, the syntax error message about it included only the first byte of that character, causing bad-encoding problems both in the report to the client and in the postmaster log file.

- Avoid “unexpected table_index_fetch_tuple call during logical decoding” error while decoding a transaction involving insertion of a column default value (Takeshi Ideriha, Hou Zhijie)

- Reduce memory consumption of logical decoding (Masahiko Sawada)

  Use a smaller default block size to store tuple data received during logical replication. This reduces memory wastage, which has been reported to be severe while processing long-running transactions, even leading to out-of-memory failures.

- In a logical replication apply worker, ensure that origin progress is not advanced during an error or apply worker shutdown (Hayato Kuroda, Shveta Malik)

  This avoids possible loss of a transaction, since once the origin progress point is advanced the source server won't send that data again.

- Re-disable sending of stateless (TLSv1.2) session tickets (Daniel Gustafsson)

A previous change to prevent sending of stateful (TLSv1.3) session tickets accidentally re-enabled sending of stateless ones. Thus, while we intended to prevent clients from thinking that TLS session resumption is supported, some still did.

- Avoid “wrong tuple length” failure when dropping a database with many ACL (permission) entries (Ayush Tiwari)
- Allow adjusting the `session_authorization` and `role` settings in parallel workers (Tom Lane)

  Our code intends to allow modifiable server settings to be set by function `SET` clauses, but not otherwise within a parallel worker. `SET` clauses failed for these two settings, though.
- Fix behavior of stable functions called from a `CALL` statement's argument list, when the `CALL` is within a PL/pgSQL `EXCEPTION` block (Tom Lane)

  As with a similar fix in our previous quarterly releases, this case allowed such functions to be passed the wrong snapshot, causing them to see stale values of rows modified since the start of the outer transaction.
- Fix “cache lookup failed for function” errors in edge cases in PL/pgSQL's `CALL` (Tom Lane)
- Fix thread safety of our fallback (non-OpenSSL) MD5 implementation on big-endian hardware (Heikki Linnakangas)

  Thread safety is not currently a concern in the server, but it is for libpq.
- Parse libpq's `keepalives` connection option in the same way as other integer-valued options (Yuto Sasaki)

  The coding used here rejected trailing whitespace in the option value, unlike other cases. This turns out to be problematic in ecpg's usage, for example.
- Avoid use of `pnstrdup()` in ecpglib (Jacob Champion)

  That function will call `exit()` on out-of-memory, which is undesirable in a library. The calling code already handles allocation failures properly.
- In ecpglib, fix out-of-bounds read when parsing incorrect datetime input (Bruce Momjian, Pavel Nekrasov)

  It was possible to try to read the location just before the start of a constant array. Real-world consequences seem minimal, though.
- Fix memory leak in psql during repeated use of `\bind` (Michael Paquier)
- Avoid hanging if an interval less than 1ms is specified in psql's `\watch` command (Andrey Borodin, Michael Paquier)

  Instead, treat this the same as an interval of zero (no wait between executions).
- Fix pg_dump's handling of identity sequences that have persistence different from their owning table's persistence (Tom Lane)

  Since v15, it's been possible to set an identity sequence to be LOGGED when its owning table is UNLOGGED or vice versa. However, pg_dump's method for recreating that situation failed in binary-upgrade mode, causing pg_upgrade to fail when such sequences are present. Fix by introducing a new option for `ADD/ALTER COLUMN GENERATED AS IDENTITY` to allow the sequence's persistence to be set correctly at creation. Note that this means a dump from a database containing such a sequence will only load into a server of this minor version or newer.
- Include the source timeline history in pg_rewind's debug output (Heikki Linnakangas)

  This was the intention to begin with, but a coding error caused the source history to always print as empty.

- Avoid trying to reindex temporary tables and indexes in vacuumdb and in parallel reindexdb (VaibhaveS, Michael Paquier, Fujii Masao, Nathan Bossart)

  Reindexing other sessions' temporary tables cannot work, but the check to skip them was missing in some code paths, leading to unwanted failures.

- Allow inspection of sequence relations in relevant functions of `contrib/pageinspect` and `contrib/pgstattuple` (Nathan Bossart, Ayush Vatsa)

  This had been allowed in the past, but it got broken during the introduction of non-default access methods for tables.

- Fix incorrect LLVM-generated code on ARM64 platforms (Thomas Munro, Anthonin Bonnefoy)

  When using JIT compilation on ARM platforms, the generated code could not support relocation distances exceeding 32 bits, allowing unlucky placement of generated code to cause server crashes on large-memory systems.

- Fix a few places that assumed that process start time (represented as a `time_t`) will fit into a `long` value (Max Johnson, Nathan Bossart)

  On platforms where `long` is 32 bits (notably Windows), this coding would fail after Y2038. Most of the failures appear only cosmetic, but notably `pg_ctl start` would hang.

- Fix building with Strawberry Perl on Windows (Andrew Dunstan)

- Update time zone data files to tzdata release 2024b (Tom Lane)

  This tzdata release changes the old System-V-compatibility zone names to duplicate the corresponding geographic zones; for example `PST8PDT` is now an alias for `America/Los_Angeles`. The main visible consequence is that for timestamps before the introduction of standardized time zones, the zone is considered to represent local mean solar time for the named location. For example, in `PST8PDT`, `timestamptz` input such as `1801-01-01 00:00` would previously have been rendered as `1801-01-01 00:00:00-08`, but now it is rendered as `1801-01-01 00:00:00-07:52:58`.

  Also, historical corrections for Mexico, Mongolia, and Portugal. Notably, `Asia/Choibalsan` is now an alias for `Asia/Ulaanbaatar` rather than being a separate zone, mainly because the differences between those zones were found to be based on untrustworthy data.

E.18. Release 16.4

Release date: 2024-08-08

This release contains a variety of fixes from 16.3. For information about new features in major release 16, see Section E.22.

E.18.1. Migration to Version 16.4

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.3, see Section E.19.

E.18.2. Changes

- Prevent unauthorized code execution during pg_dump (Masahiko Sawada)

  An attacker able to create and drop non-temporary objects could inject SQL code that would be executed by a concurrent pg_dump session with the privileges of the role running pg_dump (which is often a superuser). The attack involves replacing a sequence or similar object with a view or foreign table that will execute malicious code. To prevent this, introduce a new server parameter `restrict_nonsystem_relation_kind` that can disable expansion of non-builtin views as well as access to foreign tables, and teach pg_dump to set it when available. Note that the attack is prevented only if both pg_dump and the server it is dumping from are new enough to have this fix.

The PostgreSQL Project thanks Noah Misch for reporting this problem. (CVE-2024-7348)

- Avoid incorrect results from Merge Right Anti Join plans (Richard Guo)

  If the inner relation is known to have unique join keys, the merge could misbehave when there are duplicated join keys in the outer relation.

- Prevent infinite loop in `VACUUM` (Melanie Plageman)

  After a disconnected standby server with an old running transaction reconnected to the primary, it was possible for `VACUUM` on the primary to get confused about which tuples are removable, resulting in an infinite loop.

- Fix failure after attaching a table as a partition, if the table had previously had inheritance children (Álvaro Herrera)

- Fix `ALTER TABLE DETACH PARTITION` for cases involving inconsistent index-based constraints (Álvaro Herrera, Tender Wang)

  When a partitioned table has an index that is not associated with a constraint, but a partition has an equivalent index that is, then detaching the partition would misbehave, leaving the ex-partition's constraint with an incorrect `coninhcount` value. This would cause trouble during any further manipulations of that constraint.

- Fix partition pruning setup during `ALTER TABLE DETACH PARTITION CONCURRENTLY` (Álvaro Herrera)

  The executor assumed that no partition could be detached between planning and execution of a query on a partitioned table. This is no longer true since the introduction of `DETACH PARTITION`'s `CONCURRENTLY` option, making it possible for query execution to fail transiently when that is used.

- Correctly update a partitioned table's `pg_class.reltuples` field to zero after its last child partition is dropped (Noah Misch)

  The first `ANALYZE` on such a partitioned table must update `relhassubclass` as well, and that caused the `reltuples` update to be lost.

- Fix handling of polymorphic output arguments for procedures (Tom Lane)

  The SQL `CALL` statement did not resolve the correct data types for such arguments, leading to errors such as “cannot display a value of type anyelement”, or even outright crashes. (But `CALL` in PL/pgSQL worked correctly.)

- Fix behavior of stable functions called from a `CALL` statement's argument list (Tom Lane)

  If the `CALL` is within an atomic context (e.g. there's an outer transaction block), such functions were passed the wrong snapshot, causing them to see stale values of rows modified since the start of the outer transaction.

- Fix input of ISO-8601 “extended” time format for types `time` and `timetz` (Tom Lane)

  Re-allow cases such as `T12:34:56`.

- Detect integer overflow in `money` calculations (Joseph Koshakow)

  None of the arithmetic functions for the `money` type checked for overflow before, so they would silently give wrong answers for overflowing cases.

- Fix over-aggressive clamping of the scale argument in `round(numeric)` and `trunc(numeric)` (Dean Rasheed)

  These functions clamped their scale argument to +/-2000, but there are valid use-cases for it to be larger; the functions returned incorrect results in such cases. Instead clamp to the actual allowed range of type `numeric`.

- Fix result for `pg_size_pretty()` when applied to the smallest possible `bigint` value (Joseph Koshakow)
- Prevent `pg_sequence_last_value()` from failing on unlogged sequences on standby servers and on temporary sequences of other sessions (Nathan Bossart)

  Make it return NULL in these cases instead of throwing an error.
- Fix parsing of ignored operators in `websearch_to_tsquery()` (Tom Lane)

  Per the manual, punctuation in the input of `websearch_to_tsquery()` is ignored except for the special cases of dashes and quotes. However, parentheses and a few other characters appearing immediately before an `or` could cause `or` to be treated as a data word, rather than as an `OR` operator as expected.
- Detect another integer overflow case while computing new array dimensions (Joseph Koshakow)

  Reject applying array dimensions `[-2147483648:2147483647]` to an empty array. This is closely related to CVE-2023-5869, but appears harmless since the array still ends up empty.
- Fix unportable usage of `strnxfrm()` (Jeff Davis)

  Some code paths for non-deterministic collations could fail with errors like “pg_strnxfrm() returned unexpected result”.
- Detect another case of a new catalog cache entry becoming stale while detoasting its fields (Noah Misch)

  An in-place update occurring while we expand out-of-line fields in a catalog tuple could be missed, leading to a catalog cache entry that lacks the in-place change but is not known to be stale. This is only possible in the `pg_database` catalog, so the effects are narrow, but misbehavior is possible.
- Correctly check updatability of view columns targeted by `INSERT ... DEFAULT` (Tom Lane)

  If such a column is non-updatable, we should give an error reporting that. But the check was missed and then later code would report an unhelpful error such as “attribute number *N* not found in view targetlist”.
- Avoid reporting an unhelpful internal error for incorrect recursive queries (Tom Lane)

  Rearrange the order of error checks so that we throw an on-point error when a `WITH RECURSIVE` query does not have a self-reference within the second arm of the `UNION`, but does have one self-reference in some other place such as `ORDER BY`.
- Lock owned sequences during `ALTER TABLE SET LOGGED|UNLOGGED` (Noah Misch)

  These commands change the persistence of a table's owned sequences along with the table, but they failed to acquire lock on the sequences while doing so. This could result in losing the effects of concurrent `nextval()` calls.
- Don't throw an error if a queued `AFTER` trigger no longer exists (Tom Lane)

  It's possible for a transaction to execute an operation that queues a deferred `AFTER` trigger for later execution, and then to drop the trigger before that happens. Formerly this led to weird errors such as “could not find trigger *NNNN*”. It seems better to silently do nothing if the trigger no longer exists at the time when it would have been executed.
- Fix failure to remove `pg_init_privs` entries for column-level privileges when their table is dropped (Tom Lane)

  If an extension grants some column-level privileges on a table it creates, relevant catalog entries would remain behind after the extension is dropped. This was harmless until/unless the table's OID was re-used for another relation, when it could interfere with what pg_dump dumps for that relation.

- Fix selection of an arbiter index for `ON CONFLICT` when the desired index has expressions or predicates (Tom Lane)

  If a query using `ON CONFLICT` accesses the target table through an updatable view, it could fail with "there is no unique or exclusion constraint matching the ON CONFLICT specification", even though a matching index does exist.

- Refuse to modify a temporary table of another session with `ALTER TABLE` (Tom Lane)

  Permissions checks normally would prevent this case from arising, but it is possible to reach it by altering a parent table whose child is another session's temporary table. Throw an error if we discover that such a child table belongs to another session.

- Fix handling of extended statistics on expressions in `CREATE TABLE LIKE STATISTICS` (Tom Lane)

  The `CREATE` command failed to adjust column references in statistics expressions to the possibly-different column numbering of the new table. This resulted in invalid statistics objects that would cause problems later. A typical scenario where renumbering columns is needed is when the source table contains some dropped columns.

- Fix failure to recalculate sub-queries generated from `MIN()` or `MAX()` aggregates (Tom Lane)

  In some cases the aggregate result computed at one row of the outer query could be re-used for later rows when it should not be. This has only been seen to happen when the outer query uses `DISTINCT` that is implemented with hash aggregation, but other cases may exist.

- Re-forbid underscore in positional parameters (Erik Wienhold)

  As of v16 we allow integer literals to contain underscores. This change caused input such as `$1_234` to be taken as a single token, but it did not work correctly. It seems better to revert to the original definition in which a parameter symbol is only `$` followed by digits.

- Avoid crashing when a JIT-inlined backend function throws an error (Tom Lane)

  The error state can include pointers into the dynamically loaded module holding the JIT-compiled code (for error location strings). In some code paths the module could get unloaded before the error report is processed, leading to SIGSEGV when the location strings are accessed.

- Cope with behavioral changes in libxml2 version 2.13.x (Erik Wienhold, Tom Lane)

  Notably, we now suppress "chunk is not well balanced" errors from libxml2, unless that is the only reported error. This is to make error reports consistent between 2.13.x and earlier libxml2 versions. In earlier versions, that message was almost always redundant or outright incorrect, so 2.13.x substantially reduced the number of cases in which it's reported.

- Fix handling of subtransactions of prepared transactions when starting a hot standby server (Heikki Linnakangas)

  When starting a standby's replay at a shutdown checkpoint WAL record, transactions that had been prepared but not yet committed on the primary are correctly understood as being still in progress. But subtransactions of a prepared transaction (created by savepoints or PL/pgSQL exception blocks) were not accounted for and would be treated as aborted. That led to inconsistency if the prepared transaction was later committed.

- Prevent incorrect initialization of logical replication slots (Masahiko Sawada)

  In some cases a replication slot's start point within the WAL stream could be set to a point within a transaction, leading to assertion failures or incorrect decoding results.

- Avoid "can only drop stats once" error during replication slot creation and drop (Floris Van Nee)

- Fix resource leakage in logical replication WAL sender (Hou Zhijie)

  The walsender process leaked memory when publishing changes to a partitioned table whose partitions have row types physically different from the partitioned table's.

- Avoid memory leakage after servicing a notify or sinval interrupt (Tom Lane)

  The processing functions for these events could switch the current memory context to TopMemoryContext, resulting in session-lifespan leakage of any data allocated before the incorrect setting gets replaced. There were observable leaks associated with (at least) encoding conversion of incoming queries and parameters attached to Bind messages.

- Prevent leakage of reference counts for the shared memory block used for statistics (Anthonin Bonnefoy)

  A new backend process attaching to the statistics shared memory incremented its reference count, but failed to decrement the count when exiting. After 2^{32} sessions had been created, the reference count would overflow to zero, causing failures in all subsequent backend process starts.

- Prevent deadlocks and assertion failures during truncation of the multixact SLRU log (Heikki Linnakangas)

  A process trying to delete SLRU segments could deadlock with the checkpointer process.

- Avoid possibly missing end-of-input events on Windows sockets (Thomas Munro)

  Windows reports an FD_CLOSE event only once after the remote end of the connection disconnects. With unlucky timing, we could miss that report and wait indefinitely, or at least until a timeout elapsed, expecting more input.

- Fix buffer overread in JSON parse error reports for incomplete byte sequences (Jacob Champion)

  It was possible to walk off the end of the input buffer by a few bytes when the last bytes comprise an incomplete multi-byte character. While usually harmless, in principle this could cause a crash.

- Disable creation of stateful TLS session tickets by OpenSSL (Daniel Gustafsson)

  This avoids possible failures with clients that think receipt of a session ticket means that TLS session resumption is supported.

- When replanning a PL/pgSQL “simple expression”, check it's still simple (Tom Lane)

  Certain fairly-artificial cases, such as dropping a referenced function and recreating it as an aggregate, could lead to surprising failures such as “unexpected plan node type”.

- Fix PL/pgSQL's handling of integer ranges containing underscores (Erik Wienhold)

  As of v16 we allow integer literals to contain underscores, but PL/pgSQL failed to handle examples such as `FOR i IN 1_001..1_003`.

- Fix recursive `RECORD`-returning PL/Python functions (Tom Lane)

  If we recurse to a new call of the same function that passes a different column definition list (`AS` clause), it would fail because the inner call would overwrite the outer call's idea of what rowtype to return.

- Don't corrupt PL/Python's `TD` dictionary during a recursive trigger call (Tom Lane)

  If a PL/Python-language trigger caused another one to be invoked, the `TD` dictionary created for the inner one would overwrite the outer one's `TD` dictionary.

- Fix PL/Tcl's reporting of invalid list syntax in the result of a function returning tuple (Erik Wienhold, Tom Lane)

  Such a case could result in a crash, or in emission of misleading context information that actually refers to the previous Tcl error.

- Avoid non-thread-safe usage of `strerror()` in libpq (Peter Eisentraut)

  Certain error messages returned by OpenSSL could become garbled in multi-threaded applications.

- Avoid memory leak within pg_dump during a binary upgrade (Daniel Gustafsson)
- Ensure that `pg_restore -l` reports dependent TOC entries correctly (Tom Lane)

  If `-l` was specified together with selective-restore options such as `-n` or `-N`, dependent TOC entries such as comments would be omitted from the listing, even when an actual restore would have selected them.
- Allow `contrib/pg_stat_statements` to distinguish among utility statements appearing within SQL-language functions (Anthonin Bonnefoy)

  The SQL-language function executor failed to pass along the query ID that is computed for a utility (non `SELECT`/`INSERT`/`UPDATE`/`DELETE`/`MERGE`) statement.
- Avoid "cursor can only scan forward" error in `contrib/postgres_fdw` (Etsuro Fujita)

  This error could occur if the remote server is v15 or later and a foreign table is mapped to a non-trivial remote view.
- In `contrib/postgres_fdw`, do not send `FETCH FIRST WITH TIES` clauses to the remote server (Japin Li)

  The remote server might not implement this clause, or might interpret it differently than we would locally, so don't risk attempting remote execution.
- Avoid clashing with system-provided `<regex.h>` headers (Thomas Munro)

  This fixes a compilation failure on macOS version 15 and up.
- Fix otherwise-harmless assertion failure in Memoize cost estimation (David Rowley)
- Fix otherwise-harmless assertion failures in `REINDEX CONCURRENTLY` applied to an SP-GiST index (Tom Lane)

E.19. Release 16.3

Release date: 2024-05-09

This release contains a variety of fixes from 16.2. For information about new features in major release 16, see Section E.22.

E.19.1. Migration to Version 16.3

A dump/restore is not required for those running 16.X.

However, a security vulnerability was found in the system views `pg_stats_ext` and `pg_stats_ext_exprs`, potentially allowing authenticated database users to see data they shouldn't. If this is of concern in your installation, follow the steps in the first changelog entry below to rectify it.

Also, if you are upgrading from a version earlier than 16.2, see Section E.20.

E.19.2. Changes

- Restrict visibility of `pg_stats_ext` and `pg_stats_ext_exprs` entries to the table owner (Nathan Bossart)

  These views failed to hide statistics for expressions that involve columns the accessing user does not have permission to read. View columns such as `most_common_vals` might expose security-relevant data. The potential interactions here are not fully clear, so in the interest of erring on the side of safety, make rows in these views visible only to the owner of the associated table.

  The PostgreSQL Project thanks Lukas Fittl for reporting this problem. (CVE-2024-4317)

By itself, this fix will only fix the behavior in newly initdb'd database clusters. If you wish to apply this change in an existing cluster, you will need to do the following:

1. Find the SQL script `fix-CVE-2024-4317.sql` in the *`share`* directory of the PostgreSQL installation (typically located someplace like `/usr/share/postgresql/`). Be sure to use the script appropriate to your PostgreSQL major version. If you do not see this file, either your version is not vulnerable (only v14–v16 are affected) or your minor version is too old to have the fix.
2. In *each* database of the cluster, run the `fix-CVE-2024-4317.sql` script as superuser. In psql this would look like

   ```
   \i /usr/share/postgresql/fix-CVE-2024-4317.sql
   ```

   (adjust the file path as appropriate). Any error probably indicates that you've used the wrong script version. It will not hurt to run the script more than once.
3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. Do that with

   ```
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
   ```

   and then after fixing `template0`, undo it with

   ```
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
   ```

- Fix `INSERT` from multiple `VALUES` rows into a target column that is a domain over an array or composite type (Tom Lane)

  Such cases would either fail with surprising complaints about mismatched datatypes, or insert unexpected coercions that could lead to odd results.

- Require `SELECT` privilege on the target table for `MERGE` with a `DO NOTHING` clause (Álvaro Herrera)

  `SELECT` privilege would be required in all practical cases anyway, but require it even if the query reads no columns of the target table. This avoids an edge case in which `MERGE` would require no privileges whatever, which seems undesirable even when it's a do-nothing command.

- Fix handling of self-modified tuples in `MERGE` (Dean Rasheed)

  Throw an error if a target row joins to more than one source row, as required by the SQL standard. (The previous coding could silently ignore this condition if a concurrent update was involved.) Also, throw a non-misleading error if a target row is already updated by a later command in the current transaction, thanks to a `BEFORE` trigger or a volatile function used in the query.

- Fix incorrect pruning of NULL partition when a table is partitioned on a boolean column and the query has a boolean `IS NOT` clause (David Rowley)

  A NULL value satisfies a clause such as *`boolcol`* `IS NOT FALSE`, so pruning away a partition containing NULLs yielded incorrect answers.

- Make `ALTER FOREIGN TABLE SET SCHEMA` move any owned sequences into the new schema (Tom Lane)

  Moving a regular table to a new schema causes any sequences owned by the table to be moved to that schema too (along with indexes and constraints). This was overlooked for foreign tables, however.

- Make `ALTER TABLE ... ADD COLUMN` create identity/serial sequences with the same persistence as their owning tables (Peter Eisentraut)

  `CREATE UNLOGGED TABLE` will make any owned sequences be unlogged too. `ALTER TABLE` missed that consideration, so that an added identity column would have a logged sequence, which seems pointless.

- Improve `ALTER TABLE ... ALTER COLUMN TYPE`'s error message when there is a dependent function or publication (Tom Lane)
- In `CREATE DATABASE`, recognize strategy keywords case-insensitively for consistency with other options (Tomas Vondra)
- Fix `EXPLAIN`'s counting of heap pages accessed by a bitmap heap scan (Melanie Plageman)

  Previously, heap pages that contain no visible tuples were not counted; but it seems more consistent to count all pages returned by the bitmap index scan.
- Fix `EXPLAIN`'s output for subplans in `MERGE` (Dean Rasheed)

  `EXPLAIN` would sometimes fail to properly display subplan Params referencing variables in other parts of the plan tree.
- Avoid deadlock during removal of orphaned temporary tables (Mikhail Zhilin)

  If the session that creates a temporary table crashes without removing the table, autovacuum will eventually try to remove the orphaned table. However, an incoming session that's been assigned the same temporary namespace will do that too. If a temporary table has a dependency (such as an owned sequence) then a deadlock could result between these two cleanup attempts.
- Fix updating of visibility map state in `VACUUM` with the `DISABLE_PAGE_SKIPPING` option (Heikki Linnakangas)

  Due to an oversight, this mode caused all heap pages to be dirtied, resulting in excess I/O. Also, visibility map bits that were incorrectly set would not get cleared.
- Avoid race condition while examining per-relation frozen-XID values (Noah Misch)

  `VACUUM`'s computation of per-database frozen-XID values from per-relation values could get confused by a concurrent update of those values by another `VACUUM`.
- Fix buffer usage reporting for parallel vacuuming (Anthonin Bonnefoy)

  Buffer accesses performed by parallel workers were not getting counted in the statistics reported in `VERBOSE` mode.
- Ensure that join conditions generated from equivalence classes are applied at the correct plan level (Tom Lane)

  In versions before PostgreSQL 16, it was possible for generated conditions to be evaluated below outer joins when they should be evaluated above (after) the outer join, leading to incorrect query results. All versions have a similar hazard when considering joins to `UNION ALL` trees that have constant outputs for the join column in some `SELECT` arms.
- Fix “could not find pathkey item to sort” errors occurring while planning aggregate functions with `ORDER BY` or `DISTINCT` options (David Rowley)

  This is similar to a fix applied in 16.1, but it solves the problem for parallel plans.
- Prevent potentially-incorrect optimization of some window functions (David Rowley)

  Disable “run condition” optimization of `ntile()` and `count()` with non-constant arguments. This avoids possible misbehavior with sub-selects, typically leading to errors like “WindowFunc not found in subplan target lists”.
- Avoid unnecessary use of moving-aggregate mode with a non-moving window frame (Vallimaharajan G)

  When a plain aggregate is used as a window function, and the window frame start is specified as `UNBOUNDED PRECEDING`, the frame's head cannot move so we do not need to use the special (and more expensive) moving-aggregate mode. This optimization was intended all along, but due to a coding error it never triggered.

- Avoid use of already-freed data while planning partition-wise joins under GEQO (Tom Lane)

  This would typically end in a crash or unexpected error message.

- Avoid freeing still-in-use data in Memoize (Tender Wang, Andrei Lepikhov)

  In production builds this error frequently didn't cause any problems, as the freed data would most likely not get overwritten before it was used.

- Fix incorrectly-reported statistics kind codes in “requested statistics kind *X* is not yet built” error messages (David Rowley)

- Use a hash table instead of linear search for “catcache list” objects (Tom Lane)

  This change solves performance problems that were reported for certain operations in installations with many thousands of roles.

- Be more careful with `RECORD`-returning functions in `FROM` (Tom Lane)

  The output columns of such a function call must be defined by an `AS` clause that specifies the column names and data types. If the actual function output value doesn't match that, an error is supposed to be thrown at runtime. However, some code paths would examine the actual value prematurely, and potentially issue strange errors or suffer assertion failures if it doesn't match expectations.

- Fix confusion about the return rowtype of SQL-language procedures (Tom Lane)

  A procedure implemented in SQL language that returns a single composite-type column would cause an assertion failure or core dump.

- Add protective stack depth checks to some recursive functions (Egor Chindyaskin)

- Fix mis-rounding and overflow hazards in `date_bin()` (Moaaz Assali)

  In the case where the source timestamp is before the origin timestamp and their difference is already an exact multiple of the stride, the code incorrectly subtracted the stride anyway. Also, detect some integer-overflow cases that would have produced incorrect results.

- Detect integer overflow when adding or subtracting an `interval` to/from a `timestamp` (Joseph Koshakow)

  Some cases that should cause an out-of-range error produced an incorrect result instead.

- Avoid race condition in `pg_get_expr()` (Tom Lane)

  If the relation referenced by the argument is dropped concurrently, the function's intention is to return NULL, but sometimes it failed instead.

- Fix detection of old transaction IDs in XID status functions (Karina Litskevich)

  Transaction IDs more than 2^{31} transactions in the past could be misidentified as recent, leading to misbehavior of `pg_xact_status()` or `txid_status()`.

- Ensure that a table's freespace map won't return a page that's past the end of the table (Ronan Dunklau)

  Because the freespace map isn't WAL-logged, this was possible in edge cases involving an OS crash, a replica promote, or a PITR restore. The result would be a “could not read block” error.

- Fix file descriptor leakage when an error is thrown while waiting in `WaitEventSetWait` (Etsuro Fujita)

- Avoid corrupting exception stack if an FDW implements async append but doesn't configure any wait conditions for the Append plan node to wait for (Alexander Pyhalov)

- Throw an error if an index is accessed while it is being reindexed (Tom Lane)

Previously this was just an assertion check, but promote it into a regular runtime error. This will provide a more on-point error message when reindexing a user-defined index expression that attempts to access its own table.

- Ensure that index-only scans on `name` columns return a fully-padded value (David Rowley)

  The value physically stored in the index is truncated, and previously a pointer to that value was returned to callers. This provoked complaints when testing under valgrind. In theory it could result in crashes, though none have been reported.

- Fix race condition that could lead to reporting an incorrect conflict cause when invalidating a replication slot (Bertrand Drouvot)

- Fix race condition in deciding whether a table sync operation is needed in logical replication (Vignesh C)

  An invalidation event arriving while a subscriber identifies which tables need to be synced would be forgotten about, so that any tables newly in need of syncing might not get processed in a timely fashion.

- Fix crash with DSM allocations larger than 4GB (Heikki Linnakangas)

- Disconnect if a new server session's client socket cannot be put into non-blocking mode (Heikki Linnakangas)

  It was once theoretically possible for us to operate with a socket that's in blocking mode; but that hasn't worked fully in a long time, so fail at connection start rather than misbehave later.

- Fix inadequate error reporting with OpenSSL 3.0.0 and later (Heikki Linnakangas, Tom Lane)

  System-reported errors passed through by OpenSSL were reported with a numeric error code rather than anything readable.

- Fix thread-safety of error reporting for `getaddrinfo()` on Windows (Thomas Munro)

  A multi-threaded libpq client program could get an incorrect or corrupted error message after a network lookup failure.

- Avoid concurrent calls to `bindtextdomain()` in libpq and ecpglib (Tom Lane)

  Although GNU gettext's implementation seems to be fine with concurrent calls, the version available on Windows is not.

- Fix crash in ecpg's preprocessor if the program tries to redefine a macro that was defined on the preprocessor command line (Tom Lane)

- In ecpg, avoid issuing false “unsupported feature will be passed to server” warnings (Tom Lane)

- Ensure that the string result of ecpg's `intoasc()` function is correctly zero-terminated (Oleg Tselebrovskiy)

- In initdb's `-c` option, match parameter names case-insensitively (Tom Lane)

  The server treats parameter names case-insensitively, so this code should too. This avoids putting redundant entries into the generated `postgresql.conf` file.

- In psql, avoid leaking a query result after the query is cancelled (Tom Lane)

  This happened only when cancelling a non-last query in a query string made with `\;` separators.

- Fix pg_dumpall so that role comments, if present, will be dumped regardless of the setting of `--no-role-passwords` (Daniel Gustafsson, Álvaro Herrera)

- Skip files named `.DS_Store` in pg_basebackup, pg_checksums, and pg_rewind (Daniel Gustafsson)

  This avoids problems on macOS, where the Finder may create such files.

- Fix PL/pgSQL's parsing of single-line comments (`--`-style comments) following expressions (Erik Wienhold, Tom Lane)

  This mistake caused parse errors if such a comment followed a `WHEN` expression in a PL/pgSQL `CASE` statement.

- In `contrib/amcheck`, don't report false match failures due to short- versus long-header values (Andrey Borodin, Michael Zhilin)

  A variable-length datum in a heap tuple or index tuple could have either a short or a long header, depending on compression parameters that applied when it was made. Treat these cases as equivalent rather than complaining if there's a difference.

- Fix bugs in BRIN output functions (Tomas Vondra)

  These output functions are only used for displaying index entries in `contrib/pageinspect`, so the errors are of limited practical concern.

- In `contrib/postgres_fdw`, avoid emitting requests to sort by a constant (David Rowley)

  This could occur in cases involving `UNION ALL` with constant-emitting subqueries. Sorting by a constant is useless of course, but it also risks being misinterpreted by the remote server, leading to "ORDER BY position *`N`* is not in select list" errors.

- Make `contrib/postgres_fdw` set the remote session's time zone to `GMT` not `UTC` (Tom Lane)

  This should have the same results for practical purposes. However, `GMT` is recognized by hard-wired code in the server, while `UTC` is looked up in the timezone database. So the old code could fail in the unlikely event that the remote server's timezone database is missing entries.

- In `contrib/xml2`, avoid use of library functions that have been deprecated in recent versions of libxml2 (Dmitry Koval)
- Fix incompatibility with LLVM 18 (Thomas Munro, Dmitry Dolgov)
- Allow `make check` to work with the musl C library (Thomas Munro, Bruce Momjian, Tom Lane)

E.20. Release 16.2

Release date: 2024-02-08

This release contains a variety of fixes from 16.1. For information about new features in major release 16, see Section E.22.

E.20.1. Migration to Version 16.2

A dump/restore is not required for those running 16.X.

However, one bug was fixed that could have resulted in corruption of GIN indexes during concurrent updates. If you suspect such corruption, reindex affected indexes after installing this update.

Also, if you are upgrading from a version earlier than 16.1, see Section E.21.

E.20.2. Changes

- Tighten security restrictions within `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Heikki Linnakangas)

  One step of a concurrent refresh command was run under weak security restrictions. If a materialized view's owner could persuade a superuser or other high-privileged user to perform a concurrent refresh on that view, the view's owner could control code executed with the privileges of the user running `REFRESH`. Fix things so that all user-determined code is run as the view's owner, as expected.

The only known exploit for this error does not work in PostgreSQL 16.0 and later, so it may be that v16 is not vulnerable in practice.

The PostgreSQL Project thanks Pedro Gallegos for reporting this problem. (CVE-2024-0985)

- Fix memory leak when performing JIT inlining (Andres Freund, Daniel Gustafsson)

  There have been multiple reports of backend processes suffering out-of-memory conditions after sufficiently many JIT compilations. This fix should resolve that.

- Avoid generating incorrect partitioned-join plans (Richard Guo)

  Some uncommon situations involving lateral references could create incorrect plans. Affected queries could produce wrong answers, or odd failures such as “variable not found in subplan target list”, or executor crashes.

- Fix incorrect wrapping of subquery output expressions in PlaceHolderVars (Tom Lane)

  This fixes incorrect results when a subquery is underneath an outer join and has an output column that laterally references something outside the outer join's scope. The output column might not appear as NULL when it should do so due to the action of the outer join.

- Fix misprocessing of window function run conditions (Richard Guo)

  This oversight could lead to “WindowFunc not found in subplan target lists” errors.

- Fix detection of inner-side uniqueness for Memoize plans (Richard Guo)

  This mistake could lead to “cache entry already complete” errors.

- Fix computation of nullingrels when constant-folding field selection (Richard Guo)

  Failure to do this led to errors like “wrong varnullingrels (b) (expected (b 3)) for Var 2/2”.

- Skip inappropriate actions when `MERGE` causes a cross-partition update (Dean Rasheed)

  When executing a `MERGE UPDATE` action on a partitioned table, if the `UPDATE` is turned into a `DELETE` and `INSERT` due to changing a partition key column, skip firing `AFTER UPDATE ROW` triggers, as well as other post-update actions such as RLS checks. These actions would typically fail, which is why a regular `UPDATE` doesn't do them in such cases; `MERGE` shouldn't either.

- Cope with `BEFORE ROW DELETE` triggers in cross-partition `MERGE` updates (Dean Rasheed)

  If such a trigger attempted to prevent the update by returning NULL, `MERGE` would suffer an error or assertion failure.

- Prevent access to a no-longer-pinned buffer in `BEFORE ROW UPDATE` triggers (Alexander Lakhin, Tom Lane)

  If the tuple being updated had just been updated and moved to another page by another session, there was a narrow window where we would attempt to fetch data from the new tuple version without any pin on its buffer. In principle this could result in garbage data appearing in non-updated columns of the proposed new tuple. The odds of problems in practice seem rather low, however.

- Avoid requesting an oversize shared-memory area in parallel hash join (Thomas Munro, Andrei Lepikhov, Alexander Korotkov)

  The limiting value was too large, allowing “invalid DSA memory alloc request size” errors to occur with sufficiently large expected hash table sizes.

- Fix corruption of local buffer state when an error occurs while trying to extend a temporary table (Tender Wang)

- Fix use of wrong tuple slot while evaluating `DISTINCT` aggregates that have multiple arguments (David Rowley)

This mistake could lead to errors such as “attribute 1 of type record has wrong type”.

- Avoid assertion failures in `heap_update()` and `heap_delete()` when a tuple to be updated by a foreign-key enforcement trigger fails the extra visibility crosscheck (Alexander Lakhin)

  This error had no impact in non-assert builds.

- Fix overly tight assertion about `false_positive_rate` parameter of BRIN bloom operator classes (Alexander Lakhin)

  This error had no impact in non-assert builds, either.

- Fix possible failure during `ALTER TABLE ADD COLUMN` on a complex inheritance tree (Tender Wang)

  If a grandchild table would inherit the new column via multiple intermediate parents, the command failed with “tuple already updated by self”.

- Fix problems with duplicate token names in `ALTER TEXT SEARCH CONFIGURATION ... MAPPING` commands (Tender Wang, Michael Paquier)

- Fix `DROP ROLE` with duplicate role names (Michael Paquier)

  Previously this led to a “tuple already updated by self” failure. Instead, ignore the duplicate.

- Properly lock the associated table during `DROP STATISTICS` (Tomas Vondra)

  Failure to acquire the lock could result in “tuple concurrently deleted” errors if the `DROP` executes concurrently with `ANALYZE`.

- Fix function volatility checking for `GENERATED` and `DEFAULT` expressions (Tom Lane)

  These places could fail to detect insertion of a volatile function default-argument expression, or decide that a polymorphic function is volatile although it is actually immutable on the datatype of interest. This could lead to improperly rejecting or accepting a `GENERATED` clause, or to mistakenly applying the constant-default-value optimization in `ALTER TABLE ADD COLUMN`.

- Detect that a new catalog cache entry became stale while detoasting its fields (Tom Lane)

  We expand any out-of-line fields in a catalog tuple before inserting it into the catalog caches. That involves database access which might cause invalidation of catalog cache entries — but the new entry isn't in the cache yet, so we would miss noticing that it should get invalidated. The result is a race condition in which an already-stale cache entry could get made, and then persist indefinitely. This would lead to hard-to-predict misbehavior. Fix by rechecking the tuple's visibility after detoasting.

- Fix edge-case integer overflow detection bug on some platforms (Dean Rasheed)

  Computing `0 - INT64_MIN` should result in an overflow error, and did on most platforms. However, platforms with neither integer overflow builtins nor 128-bit integers would fail to spot the overflow, instead returning `INT64_MIN`.

- Detect Julian-date overflow when adding or subtracting an `interval` to/from a `timestamp` (Tom Lane)

  Some cases that should cause an out-of-range error produced an incorrect result instead.

- Add more checks for overflow in `interval_mul()` and `interval_div()` (Dean Rasheed)

  Some cases that should cause an out-of-range error produced an incorrect result instead.

- Allow `scram_SaltedPassword()` to be interrupted (Bowen Shi)

  With large `scram_iterations` values, this function could take a long time to run. Allow it to be interrupted by query cancel requests.

- Ensure cached statistics are discarded after a change to `stats_fetch_consistency` (Shinya Kato)

  In some code paths, it was possible for stale statistics to be returned.

- Make the `pg_file_settings` view check validity of unapplied values for settings with `backend` or `superuser-backend` context (Tom Lane)

  Invalid values were not noted in the view as intended. This escaped detection because there are very few settings in these groups.

- Match collation too when matching an existing index to a new partitioned index (Peter Eisentraut)

  Previously we could accept an index that has a different collation from the corresponding element of the partition key, possibly leading to misbehavior.

- Avoid failure if a child index is dropped concurrently with `REINDEX INDEX` on a partitioned index (Fei Changhong)

- Fix insufficient locking when cleaning up an incomplete split of a GIN index's internal page (Fei Changhong, Heikki Linnakangas)

  The code tried to do this with shared rather than exclusive lock on the buffer. This could lead to index corruption if two processes attempted the cleanup concurrently.

- Avoid premature release of buffer pin in GIN index insertion (Tom Lane)

  If an index root page split occurs concurrently with our own insertion, the code could fail with "buffer NNNN is not owned by resource owner".

- Avoid failure with partitioned SP-GiST indexes (Tom Lane)

  Trying to use an index of this kind could lead to "No such file or directory" errors.

- Fix ownership tests for large objects (Tom Lane)

  Operations on large objects that require ownership privilege failed with "unrecognized class ID: 2613", unless run by a superuser.

- Fix ownership change reporting for large objects (Tom Lane)

  A no-op `ALTER LARGE OBJECT OWNER` command (that is, one selecting the existing owner) passed the wrong class ID to the `PostAlterHook`, probably confusing any extension using that hook.

- Fix reporting of I/O timing data in `EXPLAIN (BUFFERS)` (Michael Paquier)

  The numbers labeled as "shared/local" actually refer only to shared buffers, so change that label to "shared".

- Ensure durability of `CREATE DATABASE` (Noah Misch)

  If an operating system crash occurred during or shortly after `CREATE DATABASE`, recovery could fail, or subsequent connections to the new database could fail. If a base backup was taken in that window, similar problems could be observed when trying to use the backup. The symptom would be that the database directory, `PG_VERSION` file, or `pg_filenode.map` file was missing or empty.

- Add more `LOG` messages when starting and ending recovery from a backup (Andres Freund)

  This change provides additional information in the postmaster log that may be useful for diagnosing recovery problems.

- Prevent standby servers from incorrectly processing dead index tuples during subtransactions (Fei Changhong)

  The `startedInRecovery` flag was not correctly set for a subtransaction. This affects only processing of dead index tuples. It could allow a query in a subtransaction to ignore index entries that it

should return (if they are already dead on the primary server, but not dead to the standby transaction), or to prematurely mark index entries as dead that are not yet dead on the primary. It is not clear that the latter case has any serious consequences, but it's not the intended behavior.

- Fix signal handling in walreceiver processes (Heikki Linnakangas)

  Revert a change that made walreceivers non-responsive to SIGTERM while waiting for the replication connection to be established.

- Fix integer overflow hazard in checking whether a record will fit into the WAL decoding buffer (Thomas Munro)

  This bug appears to be only latent except when running a 32-bit PostgreSQL build on a 64-bit platform.

- Fix deadlock between a logical replication apply worker, its tablesync worker, and a session process trying to alter the subscription (Shlok Kyal)

  One edge of the deadlock loop did not involve a lock wait, so the deadlock went undetected and would persist until manual intervention.

- Ensure that column default values are correctly transmitted by the pgoutput logical replication plugin (Nikhil Benesch)

  `ALTER TABLE ADD COLUMN` with a constant default value for the new column avoids rewriting existing tuples, instead expecting that reading code will insert the correct default into a tuple that lacks that column. If replication was subsequently initiated on the table, pgoutput would transmit NULL instead of the correct default for such a column, causing incorrect replication on the subscriber.

- Fix failure of logical replication's initial sync for a table with no columns (Vignesh C)

  This case generated an improperly-formatted `COPY` command.

- Re-validate a subscription's connection string before use (Vignesh C)

  This is meant to detect cases where a subscription was created without a password (which is allowed to superusers) but then the subscription owner is changed to a non-superuser.

- Return the correct status code when a new client disconnects without responding to the server's password challenge (Liu Lang, Tom Lane)

  In some cases we'd treat this as a loggable error, which was not the intention and tends to create log spam, since common clients like psql frequently do this. It may also confuse extensions that use `ClientAuthentication_hook`.

- Fix incompatibility with OpenSSL 3.2 (Tristan Partin, Bo Andreson)

  Use the BIO “app_data” field for our private storage, instead of assuming it's okay to use the “data” field. This mistake didn't cause problems before, but with 3.2 it leads to crashes and complaints about double frees.

- Be more wary about OpenSSL not setting `errno` on error (Tom Lane)

  If `errno` isn't set, assume the cause of the reported failure is read EOF. This fixes rare cases of strange error reports like “could not accept SSL connection: Success”.

- Fix file descriptor leakage when a foreign data wrapper's `ForeignAsyncRequest` function fails (Heikki Linnakangas)

- Fix minor memory leak in connection string validation for `CREATE SUBSCRIPTION` (Jeff Davis)

- Report ENOMEM errors from file-related system calls as `ERRCODE_OUT_OF_MEMORY`, not `ERRCODE_INTERNAL_ERROR` (Alexander Kuzmenkov)

- In PL/pgSQL, support SQL commands that are `CREATE FUNCTION`/`CREATE PROCEDURE` with SQL-standard bodies (Tom Lane)

Previously, such cases failed with parsing errors due to the semicolon(s) appearing in the function body.

- Fix libpq's handling of errors in pipelines (Álvaro Herrera)

  The pipeline state could get out of sync if an error is returned for reasons other than a query problem (for example, if the connection is lost). Potentially this would lead to a busy-loop in the calling application.

- Make libpq's `PQsendFlushRequest()` function flush the client output buffer under the same rules as other `PQsend` functions (Jelte Fennema-Nio)

  In pipeline mode, it may still be necessary to call `PQflush()` as well; but this change removes some inconsistency.

- Avoid race condition when libpq initializes OpenSSL support concurrently in two different threads (Willi Mann, Michael Paquier)

- Fix timing-dependent failure in GSSAPI data transmission (Tom Lane)

  When using GSSAPI encryption in non-blocking mode, libpq sometimes failed with “GSSAPI caller failed to retransmit all data needing to be retried”.

- Change initdb to always un-comment the `postgresql.conf` entries for the `lc_`*`xxx`* parameters (Kyotaro Horiguchi)

  initdb used to work this way before v16, and now it does again. The change caused initdb's `--no-locale` option to not have the intended effect on `lc_messages`.

- In pg_dump, don't dump RLS policies or security labels for extension member objects (Tom Lane, Jacob Champion)

  Previously, commands would be included in the dump to set these properties, which is really incorrect since they should be considered as internal affairs of the extension. Moreover, the restoring user might not have adequate privilege to set them, and indeed the dumping user might not have enough privilege to dump them (since dumping RLS policies requires acquiring lock on their table).

- In pg_dump, don't dump an extended statistics object if its underlying table isn't being dumped (Rian McGuire, Tom Lane)

  This conforms to the behavior for other dependent objects such as indexes.

- Properly detect out-of-memory in one code path in pg_dump (Daniel Gustafsson)

- Make it an error for a pgbench script to end with an open pipeline (Anthonin Bonnefoy)

  Previously, pgbench would behave oddly if a `\startpipeline` command lacked a matching `\endpipeline`. This seems like a scripting mistake rather than a case that pgbench needs to handle nicely, so throw an error.

- Fix crash in `contrib/intarray` if an array with an element equal to `INT_MAX` is inserted into a `gist__int_ops` index (Alexander Lakhin, Tom Lane)

- Report a better error when `contrib/pageinspect`'s `hash_bitmap_info()` function is applied to a partitioned hash index (Alexander Lakhin, Michael Paquier)

- Report a better error when `contrib/pgstattuple`'s `pgstathashindex()` function is applied to a partitioned hash index (Alexander Lakhin)

- On Windows, suppress autorun options when launching subprocesses in pg_ctl and pg_regress (Kyotaro Horiguchi)

  When launching a child process via `cmd.exe`, pass the `/D` flag to prevent executing any autorun commands specified in the registry. This avoids possibly-surprising side effects.

- Move `is_valid_ascii()` from `mb/pg_wchar.h` to `utils/ascii.h` (Jubilee Young)

  This change avoids the need to include `<simd.h>` in `pg_wchar.h`, which was causing problems for some third-party code.
- Fix compilation failures with libxml2 version 2.12.0 and later (Tom Lane)
- Fix compilation failure of `WAL_DEBUG` code on Windows (Bharath Rupireddy)
- Suppress compiler warnings from Python's header files (Peter Eisentraut, Tom Lane)

  Our preferred compiler options provoke warnings about constructs appearing in recent versions of Python's header files. When using gcc, we can suppress these warnings with a pragma.
- Avoid deprecation warning when compiling with LLVM 18 (Thomas Munro)
- Update time zone data files to tzdata release 2024a for DST law changes in Greenland, Kazakhstan, and Palestine, plus corrections for the Antarctic stations Casey and Vostok. Also historical corrections for Vietnam, Toronto, and Miquelon. (Tom Lane)

E.21. Release 16.1

Release date: 2023-11-09

This release contains a variety of fixes from 16.0. For information about new features in major release 16, see Section E.22.

E.21.1. Migration to Version 16.1

A dump/restore is not required for those running 16.X.

However, several mistakes have been discovered that could lead to certain types of indexes yielding wrong search results or being unnecessarily inefficient. It is advisable to `REINDEX` potentially-affected indexes after installing this update. See the fourth through seventh changelog entries below.

E.21.2. Changes

- Fix handling of unknown-type arguments in `DISTINCT "any"` aggregate functions (Tom Lane)

  This error led to a `text`-type value being interpreted as an `unknown`-type value (that is, a zero-terminated string) at runtime. This could result in disclosure of server memory following the `text` value.

  The PostgreSQL Project thanks Jingzhou Fu for reporting this problem. (CVE-2023-5868)
- Detect integer overflow while computing new array dimensions (Tom Lane)

  When assigning new elements to array subscripts that are outside the current array bounds, an undetected integer overflow could occur in edge cases. Memory stomps that are potentially exploitable for arbitrary code execution are possible, and so is disclosure of server memory.

  The PostgreSQL Project thanks Pedro Gallegos for reporting this problem. (CVE-2023-5869)
- Prevent the `pg_signal_backend` role from signalling background workers and autovacuum processes (Noah Misch, Jelte Fennema-Nio)

  The documentation says that `pg_signal_backend` cannot issue signals to superuser-owned processes. It was able to signal these background processes, though, because they advertise a role OID of zero. Treat that as indicating superuser ownership. The security implications of cancelling one of these process types are fairly small so far as the core code goes (we'll just start another one), but extensions might add background workers that are more vulnerable.

  Also ensure that the `is_superuser` parameter is set correctly in such processes. No specific security consequences are known for that oversight, but it might be significant for some extensions.

The PostgreSQL Project thanks Hemanth Sandrana and Mahendrakar Srinivasarao for reporting this problem. (CVE-2023-5870)

- Fix misbehavior during recursive page split in GiST index build (Heikki Linnakangas)

  Fix a case where the location of a page downlink was incorrectly tracked, and introduce some logic to allow recovering from such situations rather than silently doing the wrong thing. This error could result in incorrect answers from subsequent index searches. It may be advisable to reindex all GiST indexes after installing this update.

- Prevent de-duplication of btree index entries for `interval` columns (Noah Misch)

  There are `interval` values that are distinguishable but compare equal, for example `24:00:00` and `1 day`. This breaks assumptions made by btree de-duplication, so `interval` columns need to be excluded from de-duplication. This oversight can cause incorrect results from index-only scans. Moreover, after updating amcheck will report an error for almost all such indexes. Users should reindex any btree indexes on `interval` columns.

- Process `date` values more sanely in BRIN `datetime_minmax_multi_ops` indexes (Tomas Vondra)

  The distance calculation for dates was backward, causing poor decisions about which entries to merge. The index still produces correct results, but is much less efficient than it should be. Reindexing BRIN `minmax_multi` indexes on `date` columns is advisable.

- Process large `timestamp` and `timestamptz` values more sanely in BRIN `datetime_minmax_multi_ops` indexes (Tomas Vondra)

  Infinities were mistakenly treated as having distance zero rather than a large distance from other values, causing poor decisions about which entries to merge. Also, finite-but-very-large values (near the endpoints of the representable timestamp range) could result in internal overflows, again causing poor decisions. The index still produces correct results, but is much less efficient than it should be. Reindexing BRIN `minmax_multi` indexes on `timestamp` and `timestamptz` columns is advisable if the column contains, or has contained, infinities or large finite values.

- Avoid calculation overflows in BRIN `interval_minmax_multi_ops` indexes with extreme interval values (Tomas Vondra)

  This bug might have caused unexpected failures while trying to insert large interval values into such an index.

- Fix partition step generation and runtime partition pruning for hash-partitioned tables with multiple partition keys (David Rowley)

  Some cases involving an `IS NULL` condition on one of the partition keys could result in a crash.

- Fix inconsistent rechecking of concurrently-updated rows during `MERGE` (Dean Rasheed)

  In `READ COMMITTED` mode, an update that finds that its target row was just updated by a concurrent transaction will recheck the query's `WHERE` conditions on the updated row. `MERGE` failed to ensure that the proper rows of other joined tables were used during this recheck, possibly resulting in incorrect decisions about whether the newly-updated row should be updated again by `MERGE`.

- Correctly identify the target table in an inherited `UPDATE`/`DELETE`/`MERGE` even when the parent table is excluded by constraints (Amit Langote, Tom Lane)

  If the initially-named table is excluded by constraints, but not all its inheritance descendants are, the first non-excluded descendant was identified as the primary target table. This would lead to firing statement-level triggers associated with that table, rather than the initially-named table as should happen. In v16, the same oversight could also lead to “invalid perminfoindex 0 in RTE with relid NNNN” errors.

- Fix edge case in btree mark/restore processing of ScalarArrayOpExpr clauses (Peter Geoghegan)

When restoring an indexscan to a previously marked position, the code could miss required set-up steps if the scan had advanced exactly to the end of the matches for a ScalarArrayOpExpr (that is, an `indexcol = ANY(ARRAY[])`) clause. This could result in missing some rows that should have been fetched.

- Fix intra-query memory leak in Memoize execution (Orlov Aleksej, David Rowley)
- Fix intra-query memory leak when a set-returning function repeatedly returns zero rows (Tom Lane)
- Don't crash if `cursor_to_xmlschema()` is applied to a non-data-returning Portal (Boyu Yang)
- Fix improper sharing of origin filter condition across successive `pg_logical_slot_get_changes()` calls (Hou Zhijie)

  The origin condition set by one call of this function would be re-used by later calls that did not specify the origin argument. This was not intended.
- Throw the intended error if `pgrowlocks()` is applied to a partitioned table (David Rowley)

  Previously, a not-on-point complaint “only heap AM is supported” would be raised.
- Handle invalid indexes more cleanly in assorted SQL functions (Noah Misch)

  Report an error if `pgstatindex()`, `pgstatginindex()`, `pgstathashindex()`, or `pgstattuple()` is applied to an invalid index. If `brin_desummarize_range()`, `brin_summarize_new_values()`, `brin_summarize_range()`, or `gin_clean_pending_list()` is applied to an invalid index, do nothing except to report a debug-level message. Formerly these functions attempted to process the index, and might fail in strange ways depending on what the failed `CREATE INDEX` had left behind.
- Avoid premature memory allocation failure with long inputs to `to_tsvector()` (Tom Lane)
- Fix over-allocation of the constructed `tsvector` in `tsvectorrecv()` (Denis Erokhin)

  If the incoming vector includes position data, the binary receive function left wasted space (roughly equal to the size of the position data) in the finished `tsvector`. In extreme cases this could lead to “maximum total lexeme length exceeded” failures for vectors that were under the length limit when emitted. In any case it could lead to wasted space on-disk.
- Improve checks for corrupt PGLZ compressed data (Flavien Guedez)
- Fix `ALTER SUBSCRIPTION` so that a commanded change in the `run_as_owner` option is actually applied (Hou Zhijie)
- Fix bulk table insertion into partitioned tables (Andres Freund)

  Improper sharing of insertion state across partitions could result in failures during `COPY FROM`, typically manifesting as “could not read block NNNN in file XXXX: read only 0 of 8192 bytes” errors.
- In `COPY FROM`, avoid evaluating column default values that will not be needed by the command (Laurenz Albe)

  This avoids a possible error if the default value isn't actually valid for the column, or if the default's expression would fail in the current execution context. Such edge cases sometimes arise while restoring dumps, for example. Previous releases did not fail in this situation, so prevent v16 from doing so.
- In `COPY FROM`, fail cleanly when an unsupported encoding conversion is needed (Tom Lane)

  Recent refactoring accidentally removed the intended error check for this, such that it ended in “cache lookup failed for function 0” instead of a useful error message.
- Avoid crash in `EXPLAIN` if a parameter marked to be displayed by `EXPLAIN` has a NULL boot-time value (Xing Guo, Aleksander Alekseev, Tom Lane)

No built-in parameter fits this description, but an extension could define such a parameter.

- Ensure we have a snapshot while dropping `ON COMMIT DROP` temp tables (Tom Lane)

  This prevents possible misbehavior if any catalog entries for the temp tables have fields wide enough to require toasting (such as a very complex `CHECK` condition).

- Avoid improper response to shutdown signals in child processes just forked by `system()` (Nathan Bossart)

  This fix avoids a race condition in which a child process that has been forked off by `system()`, but hasn't yet exec'd the intended child program, might receive and act on a signal intended for the parent server process. That would lead to duplicate cleanup actions being performed, which will not end well.

- Cope with torn reads of `pg_control` in frontend programs (Thomas Munro)

  On some file systems, reading `pg_control` may not be an atomic action when the server concurrently writes that file. This is detectable via a bad CRC. Retry a few times to see if the file becomes valid before we report error.

- Avoid torn reads of `pg_control` in relevant SQL functions (Thomas Munro)

  Acquire the appropriate lock before reading `pg_control`, to ensure we get a consistent view of that file.

- Fix “could not find pathkey item to sort” errors occurring while planning aggregate functions with `ORDER BY` or `DISTINCT` options (David Rowley)

- Avoid integer overflow when computing size of backend activity string array (Jakub Wartak)

  On 64-bit machines we will allow values of `track_activity_query_size` large enough to cause 32-bit overflow when multiplied by the allowed number of connections. The code actually allocating the per-backend local array was careless about this though, and allocated the array incorrectly.

- Fix briefly showing inconsistent progress statistics for `ANALYZE` on inherited tables (Heikki Linnakangas)

  The block-level counters should be reset to zero at the same time we update the current-relation field.

- Fix the background writer to report any WAL writes it makes to the statistics counters (Nazir Bilal Yavuz)

- Fix confusion about forced-flush behavior in `pgstat_report_wal()` (Ryoga Yoshida, Michael Paquier)

  This could result in some statistics about WAL I/O being forgotten in a shutdown.

- Fix statistics tracking of temporary-table extensions (Karina Litskevich, Andres Freund)

  These were counted as normal-table writes when they should be counted as temp-table writes.

- When `track_io_timing` is enabled, include the time taken by relation extension operations as write time (Nazir Bilal Yavuz)

- Track the dependencies of cached `CALL` statements, and re-plan them when needed (Tom Lane)

  DDL commands, such as replacement of a function that has been inlined into a `CALL` argument, can create the need to re-plan a `CALL` that has been cached by PL/pgSQL. That was not happening, leading to misbehavior or strange errors such as “cache lookup failed”.

- Avoid a possible pfree-a-NULL-pointer crash after an error in OpenSSL connection setup (Sergey Shinderuk)

- Track nesting depth correctly when inspecting `RECORD`-type Vars from outer query levels (Richard Guo)

  This oversight could lead to assertion failures, core dumps, or “bogus varno” errors.

- Track hash function and negator function dependencies of ScalarArrayOpExpr plan nodes (David Rowley)

  In most cases this oversight was harmless, since these functions would be unlikely to disappear while the node's original operator remains present.

- Fix error-handling bug in `RECORD` type cache management (Thomas Munro)

  An out-of-memory error occurring at just the wrong point could leave behind inconsistent state that would lead to an infinite loop.

- Treat out-of-memory failures as fatal while reading WAL (Michael Paquier)

  Previously this would be treated as a bogus-data condition, leading to the conclusion that we'd reached the end of WAL, which is incorrect and could lead to inconsistent WAL replay.

- Fix possible recovery failure due to trying to allocate memory based on a bogus WAL record length field (Thomas Munro, Michael Paquier)

- Fix “could not duplicate handle” error occurring on Windows when `min_dynamic_shared_memory` is set above zero (Thomas Munro)

- Fix order of operations in `GenericXLogFinish` (Jeff Davis)

  This code violated the conditions required for crash safety by writing WAL before marking changed buffers dirty. No core code uses this function, but extensions do (`contrib/bloom` does, for example).

- Remove incorrect assertion in PL/Python exception handling (Alexander Lakhin)

- Fix pg_dump to dump the new `run_as_owner` option of subscriptions (Philip Warner)

  Due to this oversight, subscriptions would always be restored with `run_as_owner` set to `false`, which is not equivalent to their behavior in pre-v16 releases.

- Fix pg_restore so that selective restores will include both table-level and column-level ACLs for selected tables (Euler Taveira, Tom Lane)

  Formerly, only the table-level ACL would get restored if both types were present.

- Add logic to pg_upgrade to check for use of `abstime`, `reltime`, and `tinterval` data types (Álvaro Herrera)

  These obsolete data types were removed in PostgreSQL version 12, so check to make sure they aren't present in an older database before claiming it can be upgraded.

- Avoid false “too many client connections” errors in pgbench on Windows (Noah Misch)

- Fix vacuumdb's handling of multiple `-N` switches (Nathan Bossart, Kuwamura Masaki)

  Multiple `-N` switches should exclude tables in multiple schemas, but in fact excluded nothing due to faulty construction of a generated query.

- Fix vacuumdb to honor its `--buffer-usage-limit` option in analyze-only mode (Ryoga Yoshida, David Rowley)

- In `contrib/amcheck`, do not report interrupted page deletion as corruption (Noah Misch)

  This fix prevents false-positive reports of “the first child of leftmost target page is not leftmost of its level”, “block NNNN is not leftmost” or “left link/right link pair in index XXXX not in agreement”.

They appeared if amcheck ran after an unfinished btree index page deletion and before VACUUM had cleaned things up.

- Fix failure of contrib/btree_gin indexes on interval columns, when an indexscan using the < or <= operator is performed (Dean Rasheed)

  Such an indexscan failed to return all the entries it should.

- Add support for LLVM 16 and 17 (Thomas Munro, Dmitry Dolgov)
- Suppress assorted build-time warnings on recent macOS (Tom Lane)

  Xcode 15 (released with macOS Sonoma) changed the linker's behavior in a way that causes many duplicate-library warnings while building PostgreSQL. These were harmless, but they're annoying so avoid citing the same libraries twice. Also remove use of the -multiply_defined suppress linker switch, which apparently has been a no-op for a long time, and is now actively complained of.

- When building contrib/unaccent's rules file, fall back to using python if --with-python was not given and make variable PYTHON was not set (Japin Li)
- Remove PHOT (Phoenix Islands Time) from the default timezone abbreviations list (Tom Lane)

  Presence of this abbreviation in the default list can cause failures on recent Debian and Ubuntu releases, as they no longer install the underlying tzdb entry by default. Since this is a made-up abbreviation for a zone with a total human population of about two dozen, it seems unlikely that anyone will miss it. If someone does, they can put it back via a custom abbreviations file.

E.22. Release 16

Release date: 2023-09-14

E.22.1. Overview

PostgreSQL 16 contains many new features and enhancements, including:

- Allow parallelization of FULL and internal right OUTER hash joins
- Allow logical replication from standby servers
- Allow logical replication subscribers to apply large transactions in parallel
- Allow monitoring of I/O statistics using the new pg_stat_io view
- Add SQL/JSON constructors and identity functions
- Improve performance of vacuum freezing
- Add support for regular expression matching of user and database names in pg_hba.conf, and user names in pg_ident.conf

The above items and other new features of PostgreSQL 16 are explained in more detail in the sections below.

E.22.2. Migration to Version 16

A dump/restore using pg_dumpall or use of pg_upgrade or logical replication is required for those wishing to migrate data from any previous release. See Section 18.6 for general information on migrating to new major releases.

Version 16 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Change assignment rules for PL/pgSQL bound cursor variables (Tom Lane)

Previously, the string value of such variables was set to match the variable name during cursor assignment; now it will be assigned during OPEN, and will not match the variable name. To restore the previous behavior, assign the desired portal name to the cursor variable before OPEN.

- Disallow NULLS NOT DISTINCT indexes for primary keys (Daniel Gustafsson)
- Change REINDEX DATABASE and reindexdb to not process indexes on system catalogs (Simon Riggs)

  Processing such indexes is still possible using REINDEX SYSTEM and reindexdb --system.
- Tighten GENERATED expression restrictions on inherited and partitioned tables (Amit Langote, Tom Lane)

  Columns of parent/partitioned and child/partition tables must all have the same generation status, though now the actual generation expressions can be different.
- Remove pg_walinspect functions pg_get_wal_records_info_till_end_of_wal() and pg_get_wal_stats_till_end_of_wal() (Bharath Rupireddy)
- Rename server variable force_parallel_mode to debug_parallel_query (David Rowley)
- Remove the ability to create views manually with ON SELECT rules (Tom Lane)
- Remove the server variable vacuum_defer_cleanup_age (Andres Freund)

  This has been unnecessary since hot_standby_feedback and replication slots were added.
- Remove server variable promote_trigger_file (Simon Riggs)

  This was used to promote a standby to primary, but is now more easily accomplished with pg_ctl promote or pg_promote().
- Role inheritance now controls the default inheritance status of member roles added during GRANT (Robert Haas)

  The role's default inheritance behavior can be overridden with the new GRANT ... WITH INHERIT clause. This allows inheritance of some roles and not others because the members' inheritance status is set at GRANT time. Previously the inheritance status of member roles was controlled only by the role's inheritance status, and changes to a role's inheritance status affected all previous and future member roles.
- Restrict the privileges of CREATEROLE and its ability to modify other roles (Robert Haas)

  Previously roles with CREATEROLE privileges could change many aspects of any non-superuser role. Such changes, including adding members, now require the role requesting the change to have ADMIN OPTION permission. For example, they can now change the CREATEDB, REPLICATION, and BYPASSRLS properties only if they also have those permissions.
- Remove symbolic links for the postmaster binary (Peter Eisentraut)

E.22.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 16 and the previous major release.

E.22.3.1. Server

E.22.3.1.1. Optimizer

- Allow incremental sorts in more cases, including DISTINCT (David Rowley)
- Add the ability for aggregates having ORDER BY or DISTINCT to use pre-sorted data (David Rowley)

  The new server variable enable_presorted_aggregate can be used to disable this.

- Allow memoize atop a UNION ALL (Richard Guo)
- Allow anti-joins to be performed with the non-nullable input as the inner relation (Richard Guo)
- Allow parallelization of FULL and internal right OUTER hash joins (Melanie Plageman, Thomas Munro)
- Improve the accuracy of GIN index access optimizer costs (Ronan Dunklau)

E.22.3.1.2. General Performance

- Allow more efficient addition of heap and index pages (Andres Freund)
- During non-freeze operations, perform page freezing where appropriate (Peter Geoghegan)

  This makes full-table freeze vacuums less necessary.
- Allow window functions to use the faster ROWS mode internally when RANGE mode is active but unnecessary (David Rowley)
- Allow optimization of always-increasing window functions ntile(), cume_dist() and percent_rank() (David Rowley)
- Allow aggregate functions string_agg() and array_agg() to be parallelized (David Rowley)
- Improve performance by caching RANGE and LIST partition lookups (Amit Langote, Hou Zhijie, David Rowley)
- Allow control of the shared buffer usage by vacuum and analyze (Melanie Plageman)

  The VACUUM/ANALYZE option is BUFFER_USAGE_LIMIT, and the vacuumdb option is --buffer-usage-limit. The default value is set by server variable vacuum_buffer_usage_limit, which also controls autovacuum.
- Support wal_sync_method=fdatasync on Windows (Thomas Munro)
- Allow HOT updates if only BRIN-indexed columns are updated (Matthias van de Meent, Josef Simanek, Tomas Vondra)
- Improve the speed of updating the process title (David Rowley)
- Allow xid/subxid searches and ASCII string detection to use vector operations (Nathan Bossart, John Naylor)

  ASCII detection is particularly useful for COPY FROM. Vector operations are also used for some C array searches.
- Reduce overhead of memory allocations (Andres Freund, David Rowley)

E.22.3.1.3. Monitoring

- Add system view pg_stat_io view to track I/O statistics (Melanie Plageman)
- Record statistics on the last sequential and index scans on tables (Dave Page)

  This information appears in pg_stat_*_tables and pg_stat_*_indexes.
- Record statistics on the occurrence of updated rows moving to new pages (Corey Huinker)

  The pg_stat_*_tables column is n_tup_newpage_upd.
- Add speculative lock information to the pg_locks system view (Masahiko Sawada, Noriyoshi Shinoda)

  The transaction id is displayed in the transactionid column and the speculative insertion token is displayed in the objid column.

- Add the display of prepared statement result types to the pg_prepared_statements view (Dagfinn Ilmari Mannsåker)
- Create subscription statistics entries at subscription creation time so stats_reset is accurate (Andres Freund)

  Previously entries were created only when the first statistics were reported.
- Correct the I/O accounting for temp relation writes shown in pg_stat_database (Melanie Plageman)
- Add function pg_stat_get_backend_subxact() to report on a session's subtransaction cache (Dilip Kumar)
- Have pg_stat_get_backend_idset(), pg_stat_get_backend_activity(), and related functions use the unchanging backend id (Nathan Bossart)

  Previously the index values might change during the lifetime of the session.
- Report stand-alone backends with a special backend type (Melanie Plageman)
- Add wait event SpinDelay to report spinlock sleep delays (Andres Freund)
- Create new wait event DSMAllocate to indicate waiting for dynamic shared memory allocation (Thomas Munro)

  Previously this type of wait was reported as DSMFillZeroWrite, which was also used by mmap() allocations.
- Add the database name to the process title of logical WAL senders (Tatsuhiro Nakamori)

  Physical WAL senders do not display a database name.
- Add checkpoint and REDO LSN information to log_checkpoints messages (Bharath Rupireddy, Kyotaro Horiguchi)
- Provide additional details during client certificate failures (Jacob Champion)

E.22.3.1.4. Privileges

- Add predefined role pg_create_subscription with permission to create subscriptions (Robert Haas)
- Allow subscriptions to not require passwords (Robert Haas)

  This is accomplished with the option password_required=false.
- Simplify permissions for LOCK TABLE (Jeff Davis)

  Previously a user's ability to perform LOCK TABLE at various lock levels was limited to the lock levels required by the commands they had permission to execute on the table. For example, someone with UPDATE permission could perform all lock levels except ACCESS SHARE, even though it was a lesser lock level. Now users can issue lesser lock levels if they already have permission for greater lock levels.
- Allow ALTER GROUP group_name ADD USER user_name to be performed with ADMIN OPTION (Robert Haas)

  Previously CREATEROLE permission was required.
- Allow GRANT to use WITH ADMIN TRUE/FALSE syntax (Robert Haas)

  Previously only the WITH ADMIN OPTION syntax was supported.
- Allow roles that create other roles to automatically inherit the new role's rights or the ability to SET ROLE to the new role (Robert Haas, Shi Yu)

This is controlled by server variable createrole_self_grant.

- Prevent users from changing the default privileges of non-inherited roles (Robert Haas)

  This is now only allowed for inherited roles.

- When granting role membership, require the granted-by role to be a role that has appropriate permissions (Robert Haas)

  This is a requirement even when a non-bootstrap superuser is granting role membership.

- Allow non-superusers to grant permissions using a granted-by user that is not the current user (Robert Haas)

  The current user still must have sufficient permissions given by the specified granted-by user.

- Add GRANT to control permission to use SET ROLE (Robert Haas)

  This is controlled by a new GRANT ... SET option.

- Add dependency tracking to roles which have granted privileges (Robert Haas)

  For example, removing ADMIN OPTION will fail if there are privileges using that option; CASCADE must be used to revoke dependent permissions.

- Add dependency tracking of grantors for GRANT records (Robert Haas)

  This guarantees that pg_auth_members.grantor values are always valid.

- Allow multiple role membership records (Robert Haas)

  Previously a new membership grant would remove a previous matching membership grant, even if other aspects of the grant did not match.

- Prevent removal of superuser privileges for the bootstrap user (Robert Haas)

  Restoring such users could lead to errors.

- Allow makeaclitem() to accept multiple privilege names (Robins Tharakan)

  Previously only a single privilege name, like SELECT, was accepted.

E.22.3.1.5. Server Configuration

- Add support for Kerberos credential delegation (Stephen Frost)

  This is enabled with server variable gss_accept_delegation and libpq connection parameter gssdelegation.

- Allow the SCRAM iteration count to be set with server variable scram_iterations (Daniel Gustafsson)

- Improve performance of server variable management (Tom Lane)

- Tighten restrictions on which server variables can be reset (Masahiko Sawada)

  Previously, while certain variables, like transaction_isolation, were not affected by RESET ALL, they could be individually reset in inappropriate situations.

- Move various postgresql.conf items into new categories (Shinya Kato)

  This also affects the categories displayed in the pg_settings view.

- Prevent configuration file recursion beyond 10 levels (Julien Rouhaud)

- Allow autovacuum to more frequently honor changes to delay settings (Melanie Plageman)

Rather than honor changes only at the start of each relation, honor them at the start of each block.

- Remove restrictions that archive files be durably renamed (Nathan Bossart)

  The archive_command command is now more likely to be called with already-archived files after a crash.

- Prevent archive_library and archive_command from being set at the same time (Nathan Bossart)

  Previously archive_library would override archive_command.

- Allow the postmaster to terminate children with an abort signal (Tom Lane)

  This allows collection of a core dump for a stuck child process. This is controlled by send_abort_for_crash and send_abort_for_kill. The postmaster's -T switch is now the same as setting send_abort_for_crash.

- Remove the non-functional postmaster -n option (Tom Lane)
- Allow the server to reserve backend slots for roles with pg_use_reserved_connections membership (Nathan Bossart)

  The number of reserved slots is set by server variable reserved_connections.

- Allow huge pages to work on newer versions of Windows 10 (Thomas Munro)

  This adds the special handling required to enable huge pages on newer versions of Windows 10.

- Add debug_io_direct setting for developer usage (Thomas Munro, Andres Freund, Bharath Rupireddy)

  While primarily for developers, wal_sync_method=open_sync/open_datasync has been modified to not use direct I/O with wal_level=minimal; this is now enabled with debug_io_direct=wal.

- Add function pg_split_walfile_name() to report the segment and timeline values of WAL file names (Bharath Rupireddy)

E.22.3.1.6. pg_hba.conf

- Add support for regular expression matching on database and role entries in pg_hba.conf (Bertrand Drouvot)

  Regular expression patterns are prefixed with a slash. Database and role names that begin with slashes need to be double-quoted if referenced in pg_hba.conf.

- Improve user-column handling of pg_ident.conf to match pg_hba.conf (Jelte Fennema)

  Specifically, add support for all, role membership with +, and regular expressions with a leading slash. Any user name that matches these patterns must be double-quoted.

- Allow include files in pg_hba.conf and pg_ident.conf (Julien Rouhaud)

  These are controlled by include, include_if_exists, and include_dir. System views pg_hba_file_rules and pg_ident_file_mappings now display the file name.

- Allow pg_hba.conf tokens to be of unlimited length (Tom Lane)
- Add rule and map numbers to the system view pg_hba_file_rules (Julien Rouhaud)

E.22.3.1.7. Localization

- Determine the default encoding from the locale when using ICU (Jeff Davis)

  Previously the default was always UTF-8.

- Have CREATE DATABASE and CREATE COLLATION's LOCALE options, and initdb and createdb --locale options, control non-libc collation providers (Jeff Davis)

  Previously they only controlled libc providers.

- Add predefined collations unicode and ucs_basic (Peter Eisentraut)

  This only works if ICU support is enabled.

- Allow custom ICU collation rules to be created (Peter Eisentraut)

  This is done using CREATE COLLATION's new RULES clause, as well as new options for CREATE DATABASE, createdb, and initdb.

- Allow Windows to import system locales automatically (Juan José Santamaría Flecha)

  Previously, only ICU locales could be imported on Windows.

E.22.3.2. Logical Replication

- Allow logical decoding on standbys (Bertrand Drouvot, Andres Freund, Amit Khandekar)

  Snapshot WAL records are required for logical slot creation but cannot be created on standbys. To avoid delays, the new function pg_log_standby_snapshot() allows creation of such records.

- Add server variable to control how logical decoding publishers transfer changes and how subscribers apply them (Shi Yu)

  The variable is debug_logical_replication_streaming.

- Allow logical replication initial table synchronization to copy rows in binary format (Melih Mutlu)

  This is only possible for subscriptions marked as binary.

- Allow parallel application of logical replication (Hou Zhijie, Wang Wei, Amit Kapila)

  The CREATE SUBSCRIPTION STREAMING option now supports parallel to enable application of large transactions by parallel workers. The number of parallel workers is controlled by the new server variable max_parallel_apply_workers_per_subscription. Wait events LogicalParallelApplyMain, LogicalParallelApplyStateChange, and LogicalApplySendData were also added. Column leader_pid was added to system view pg_stat_subscription to track parallel activity.

- Improve performance for logical replication apply without a primary key (Onder Kalaci, Amit Kapila)

  Specifically, REPLICA IDENTITY FULL can now use btree indexes rather than sequentially scanning the table to find matches.

- Allow logical replication subscribers to process only changes that have no origin (Vignesh C, Amit Kapila)

  This can be used to avoid replication loops. This is controlled by the new CREATE SUBSCRIPTION ... ORIGIN option.

- Perform logical replication SELECT and DML actions as the table owner (Robert Haas)

  This improves security and now requires subscription owners to be either superusers or to have SET ROLE permission on all roles owning tables in the replication set. The previous behavior of performing all operations as the subscription owner can be enabled with the subscription run_as_owner option.

- Have wal_retrieve_retry_interval operate on a per-subscription basis (Nathan Bossart)

  Previously the retry time was applied globally. This also adds wait events >LogicalRepLauncherDSA and LogicalRepLauncherHash.

E.22.3.3. Utility Commands

- Add EXPLAIN option GENERIC_PLAN to display the generic plan for a parameterized query (Laurenz Albe)
- Allow a COPY FROM value to map to a column's DEFAULT (Israel Barth Rubio)
- Allow COPY into foreign tables to add rows in batches (Andrey Lepikhov, Etsuro Fujita)

  This is controlled by the postgres_fdw option batch_size.
- Allow the STORAGE type to be specified by CREATE TABLE (Teodor Sigaev, Aleksander Alekseev)

  Previously only ALTER TABLE could control this.
- Allow truncate triggers on foreign tables (Yugo Nagata)
- Allow VACUUM and vacuumdb to only process TOAST tables (Nathan Bossart)

  This is accomplished by having VACUUM turn off PROCESS_MAIN or by vacuumdb using the --no-process-main option.
- Add VACUUM options to skip or update all frozen statistics (Tom Lane, Nathan Bossart)

  The options are SKIP_DATABASE_STATS and ONLY_DATABASE_STATS.
- Change REINDEX DATABASE and REINDEX SYSTEM to no longer require an argument (Simon Riggs)

  Previously the database name had to be specified.
- Allow CREATE STATISTICS to generate a statistics name if none is specified (Simon Riggs)

E.22.3.4. Data Types

- Allow non-decimal integer literals (Peter Eisentraut)

  For example, 0x42F, 0o273, and 0b100101.
- Allow NUMERIC to process hexadecimal, octal, and binary integers of any size (Dean Rasheed)

  Previously only unquoted eight-byte integers were supported with these non-decimal bases.
- Allow underscores in integer and numeric constants (Peter Eisentraut, Dean Rasheed)

  This can improve readability for long strings of digits.
- Accept the spelling +infinity in datetime input (Vik Fearing)
- Prevent the specification of epoch and infinity together with other fields in datetime strings (Joseph Koshakow)
- Remove undocumented support for date input in the form *Y*yearM*M*monthD*D*day (Joseph Koshakow)
- Add functions pg_input_is_valid() and pg_input_error_info() to check for type conversion errors (Tom Lane)

E.22.3.5. General Queries

- Allow subqueries in the FROM clause to omit aliases (Dean Rasheed)
- Add support for enhanced numeric literals in SQL/JSON paths (Peter Eisentraut)

  For example, allow hexadecimal, octal, and binary integers and underscores between digits.

E.22.3.6. Functions

- Add SQL/JSON constructors (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov, Amit Langote)

The new functions JSON_ARRAY(), JSON_ARRAYAGG(), JSON_OBJECT(), and JSON_OBJECTAGG() are part of the SQL standard.

- Add SQL/JSON object checks (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov, Amit Langote, Andrew Dunstan)

  The IS JSON checks include checks for values, arrays, objects, scalars, and unique keys.
- Allow JSON string parsing to use vector operations (John Naylor)
- Improve the handling of full text highlighting function ts_headline() for OR and NOT expressions (Tom Lane)
- Add functions to add, subtract, and generate timestamptz values in a specified time zone (Przemyslaw Sztoch, Gurjeet Singh)

  The functions are date_add(), date_subtract(), and generate_series().
- Change date_trunc(unit, timestamptz, time_zone) to be an immutable function (Przemyslaw Sztoch)

  This allows the creation of expression indexes using this function.
- Add server variable SYSTEM_USER (Bertrand Drouvot)

  This reports the authentication method and its authenticated user.
- Add functions array_sample() and array_shuffle() (Martin Kalcher)
- Add aggregate function ANY_VALUE() which returns any value from a set (Vik Fearing)
- Add function random_normal() to supply normally-distributed random numbers (Paul Ramsey)
- Add error function erf() and its complement erfc() (Dean Rasheed)
- Improve the accuracy of numeric power() for integer exponents (Dean Rasheed)
- Add XMLSERIALIZE() option INDENT to pretty-print its output (Jim Jones)
- Change pg_collation_actual_version() to return a reasonable value for the default collation (Jeff Davis)

  Previously it returned NULL.
- Allow pg_read_file() and pg_read_binary_file() to ignore missing files (Kyotaro Horiguchi)
- Add byte specification (B) to pg_size_bytes() (Peter Eisentraut)
- Allow to_reg* functions to accept numeric OIDs as input (Tom Lane)

E.22.3.7. PL/pgSQL

- Add the ability to get the current function's OID in PL/pgSQL (Pavel Stehule)

  This is accomplished with GET DIAGNOSTICS variable = PG_ROUTINE_OID.

E.22.3.8. libpq

- Add libpq connection option require_auth to specify a list of acceptable authentication methods (Jacob Champion)

  This can also be used to disallow certain authentication methods.
- Allow multiple libpq-specified hosts to be randomly selected (Jelte Fennema)

  This is enabled with load_balance_hosts=random and can be used for load balancing.
- Add libpq option sslcertmode to control transmission of the client certificate (Jacob Champion)

The option values are `disable`, `allow`, and `require`.

- Allow libpq to use the system certificate pool for certificate verification (Jacob Champion, Thomas Habets)

  This is enabled with `sslrootcert=system`, which also enables `sslmode=verify-full`.

E.22.3.9. Client Applications

- Allow `ECPG` variable declarations to use typedef names that match unreserved SQL keywords (Tom Lane)

  This change does prevent keywords which match C typedef names from being processed as keywords in later `EXEC SQL` blocks.

- Allow psql to control the maximum width of header lines in expanded format (Platon Pronko)

  This is controlled by `xheader_width`.

- Add psql command `\drg` to show role membership details (Pavel Luzanov)

  The `Member of` output column has been removed from `\du` and `\dg` because this new command displays this information in more detail.

- Allow psql's access privilege commands to show system objects (Nathan Bossart)

  The options are `\dpS` and `\zS`.

- Add `FOREIGN` designation to psql `\d+` for foreign table children and partitions (Ian Lawrence Barwick)

- Prevent `\df+` from showing function source code (Isaac Morland)

  Function bodies are more easily viewed with `\sf`.

- Allow psql to submit queries using the extended query protocol (Peter Eisentraut)

  Passing arguments to such queries is done using the new psql `\bind` command.

- Allow psql `\watch` to limit the number of executions (Andrey Borodin)

  The `\watch` options can now be named when specified.

- Detect invalid values for psql `\watch`, and allow zero to specify no delay (Andrey Borodin)

- Allow psql scripts to obtain the exit status of shell commands and queries (Corey Huinker, Tom Lane)

  The new psql control variables are `SHELL_ERROR` and `SHELL_EXIT_CODE`.

- Various psql tab completion improvements (Vignesh C, Aleksander Alekseev, Dagfinn Ilmari Mannsåker, Shi Yu, Michael Paquier, Ken Kato, Peter Smith)

E.22.3.9.2. pg_dump

- Add pg_dump control of dumping child tables and partitions (Gilles Darold)

  The new options are `--table-and-children`, `--exclude-table-and-children`, and `--exclude-table-data-and-children`.

- Add LZ4 and Zstandard compression to pg_dump (Georgios Kokolatos, Justin Pryzby)

- Allow pg_dump and pg_basebackup to use `long` mode for compression (Justin Pryzby)

- Improve pg_dump to accept a more consistent compression syntax (Georgios Kokolatos)

Options like `--compress=gzip:5`.

E.22.3.10. Server Applications

- Add initdb option to set server variables for the duration of initdb and all future server starts (Tom Lane)

  The option is `-c name=value`.

- Add options to createuser to control more user options (Shinya Kato)

  Specifically, the new options control the valid-until date, bypassing of row-level security, and role membership.

- Deprecate createuser option `--role` (Nathan Bossart)

  This option could be easily confused with new createuser role membership options, so option `--member-of` has been added with the same functionality. The `--role` option can still be used.

- Allow control of vacuumdb schema processing (Gilles Darold)

  These are controlled by options `--schema` and `--exclude-schema`.

- Use new `VACUUM` options to improve the performance of vacuumdb (Tom Lane, Nathan Bossart)

- Have pg_upgrade set the new cluster's locale and encoding (Jeff Davis)

  This removes the requirement that the new cluster be created with the same locale and encoding settings.

- Add pg_upgrade option to specify the default transfer mode (Peter Eisentraut)

  The option is `--copy`.

- Improve pg_basebackup to accept numeric compression options (Georgios Kokolatos, Michael Paquier)

  Options like `--compress=server-5` are now supported.

- Fix pg_basebackup to handle tablespaces stored in the `PGDATA` directory (Robert Haas)

- Add pg_waldump option `--save-fullpage` to dump full page images (David Christensen)

- Allow pg_waldump options `-t`/`--timeline` to accept hexadecimal values (Peter Eisentraut)

- Add support for progress reporting to pg_verifybackup (Masahiko Sawada)

- Allow pg_rewind to properly track timeline changes (Heikki Linnakangas)

  Previously if pg_rewind was run after a timeline switch but before a checkpoint was issued, it might incorrectly determine that a rewind was unnecessary.

- Have pg_receivewal and pg_recvlogical cleanly exit on `SIGTERM` (Christoph Berg)

  This signal is often used by systemd.

E.22.3.11. Source Code

- Build ICU support by default (Jeff Davis)

  This removes build flag `--with-icu` and adds flag `--without-icu`.

- Add support for SSE2 (Streaming SIMD Extensions 2) vector operations on x86-64 architectures (John Naylor)

- Add support for Advanced SIMD (Single Instruction Multiple Data) (NEON) instructions on ARM architectures (Nathan Bossart)

- Have Windows binaries built with MSVC use `RandomizedBaseAddress` (ASLR) (Michael Paquier)

  This was already enabled on MinGW builds.
- Prevent extension libraries from exporting their symbols by default (Andres Freund, Tom Lane)

  Functions that need to be called from the core backend or other extensions must now be explicitly marked `PGDLLEXPORT`.
- Require Windows 10 or newer versions (Michael Paquier, Juan José Santamaría Flecha)

  Previously Windows Vista and Windows XP were supported.
- Require Perl version 5.14 or later (John Naylor)
- Require Bison version 2.3 or later (John Naylor)
- Require Flex version 2.5.35 or later (John Naylor)
- Require MIT Kerberos for GSSAPI support (Stephen Frost)
- Remove support for Visual Studio 2013 (Michael Paquier)
- Remove support for HP-UX (Thomas Munro)
- Remove support for HP/Intel Itanium (Thomas Munro)
- Remove support for M68K, M88K, M32R, and SuperH CPU architectures (Thomas Munro)
- Remove libpq support for SCM credential authentication (Michael Paquier)

  Backend support for this authentication method was removed in PostgresSQL 9.1.
- Add meson build system (Andres Freund, Nazir Bilal Yavuz, Peter Eisentraut)

  This eventually will replace the Autoconf and Windows-based MSVC build systems.
- Allow control of the location of the openssl binary used by the build system (Peter Eisentraut)

  Make finding openssl program a configure or meson option
- Add build option to allow testing of small table segment sizes (Andres Freund)

  The build options are `--with-segsize-blocks` and `-Dsegsize_blocks`.
- Add pgindent options (Andrew Dunstan)

  The new options are `--show-diff`, `--silent-diff`, `--commit`, and `--help`, and allow multiple `--exclude` options. Also require the typedef file to be explicitly specified. Options `--code-base` and `--build` were also removed.
- Add pg_bsd_indent source code to the main tree (Tom Lane)
- Improve make_ctags and make_etags (Yugo Nagata)
- Adjust `pg_attribute` columns for efficiency (Peter Eisentraut)

E.22.3.12. Additional Modules

- Improve use of extension-based indexes on boolean columns (Zongliang Quan, Tom Lane)
- Add support for Daitch-Mokotoff Soundex to fuzzystrmatch (Dag Lem)
- Allow auto_explain to log values passed to parameterized statements (Dagfinn Ilmari Mannsåker)

  This affects queries using server-side `PREPARE`/`EXECUTE` and client-side parse/bind. Logging is controlled by `auto_explain.log_parameter_max_length`; by default query parameters will be logged with no length restriction.

- Have auto_explain's `log_verbose` mode honor the value of `compute_query_id` (Atsushi Torikoshi)

  Previously even if `compute_query_id` was enabled, `log_verbose` was not showing the query identifier.
- Change the maximum length of ltree labels from 256 to 1000 and allow hyphens (Garen Torikian)
- Have `pg_stat_statements` normalize constants used in utility commands (Michael Paquier)

  Previously constants appeared instead of placeholders, e.g., `$1`.
- Add pg_walinspect function `pg_get_wal_block_info()` to report WAL block information (Michael Paquier, Melanie Plageman, Bharath Rupireddy)
- Change how pg_walinspect functions `pg_get_wal_records_info()` and `pg_get_wal_stats()` interpret ending LSNs (Bharath Rupireddy)

  Previously ending LSNs which represent nonexistent WAL locations would generate an error, while they will now be interpreted as the end of the WAL.
- Add detailed descriptions of WAL records in pg_walinspect and pg_waldump (Melanie Plageman, Peter Geoghegan)
- Add pageinspect function `bt_multi_page_stats()` to report statistics on multiple pages (Hamid Akhtar)

  This is similar to `bt_page_stats()` except it can report on a range of pages.
- Add empty range output column to pageinspect function `brin_page_items()` (Tomas Vondra)
- Redesign archive modules to be more flexible (Nathan Bossart)

  Initialization changes will require modules written for older versions of Postgres to be updated.
- Correct inaccurate pg_stat_statements row tracking extended query protocol statements (Sami Imseih)
- Add pg_buffercache function `pg_buffercache_usage_counts()` to report usage totals (Nathan Bossart)
- Add pg_buffercache function `pg_buffercache_summary()` to report summarized buffer statistics (Melih Mutlu)
- Allow the schemas of required extensions to be referenced in extension scripts using the new syntax `@extschema:referenced_extension_name@` (Regina Obe)
- Allow required extensions to be marked as non-relocatable using `no_relocate` (Regina Obe)

  This allows `@extschema:referenced_extension_name@` to be treated as a constant for the lifetime of the extension.

E.22.3.12.1. postgres_fdw

- Allow postgres_fdw to do aborts in parallel (Etsuro Fujita)

  This is enabled with postgres_fdw option `parallel_abort`.
- Make `ANALYZE` on foreign postgres_fdw tables more efficient (Tomas Vondra)

  The postgres_fdw option `analyze_sampling` controls the sampling method.
- Restrict shipment of `reg*` type constants in postgres_fdw to those referencing built-in objects or extensions marked as shippable (Tom Lane)
- Have postgres_fdw and dblink handle interrupts during connection establishment (Andres Freund)

E.22.4. Acknowledgments

E.23. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Enterprise 16 release, these prior versions were supported:

- Postgres Pro Enterprise 15: *https://postgrespro.com/docs/enterprise/15/release.html*
- Postgres Pro Enterprise 14: *https://postgrespro.com/docs/enterprise/14/release.html*
- Postgres Pro Enterprise 13: *https://postgrespro.com/docs/enterprise/13/release.html*
- Postgres Pro Enterprise 12: *https://postgrespro.com/docs/enterprise/12/release.html*
- Postgres Pro Enterprise 11: *https://postgrespro.com/docs/enterprise/11/release.html*

Appendix F. Additional Supplied Modules and Extensions Shipped in postgrespro-ent-16-contrib

This appendix, Appendix G, Appendix H, and Appendix I contain information on the optional components available in the Postgres Pro Enterprise distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system. They are separate mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix, Appendix G, Appendix H cover the extensions and other server plug-in modules. Appendix I covers the utility programs.

Many components supply new user-defined functions, operators, or types, packaged as *extensions*. To make use of one of these extensions, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a CREATE EXTENSION command. In a fresh database, you can simply do

```
CREATE EXTENSION extension_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in every database in which you want the extension's facilities to be available. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all extensions, the `CREATE EXTENSION` command must be run by a database superuser, unless the extension is considered “trusted”. Trusted extensions can be run by any user who has `CREATE` privilege on the current database. Extensions that are trusted are identified as such in the sections that follow. Generally, trusted extensions are ones that cannot provide access to outside-the-database functionality.

The following extensions are trusted in a default installation:

btree_gin	fuzzystrmatch	ltree	tcn
btree_gist	hstore	pgcrypto	tsm_system_rows
citext	intarray	pg_trgm	tsm_system_time
cube	isn	seg	unaccent
dict_int	lo	tablefunc	uuid-ossp

Many extensions allow you to install their objects in a schema of your choice. To do that, add `SCHEMA` *schema_name* to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these components are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of shared_preload_libraries. See the documentation of each component for details.

This appendix contains modules and extensions that are made available in Postgres Pro Enterprise as a separate subpackage `postgrespro-ent-16-contrib`. Note that the toastapi extension to add custom TOASTers is also available in `postgrespro-ent-16-contrib` (see Section 74.2.3 for details).

F.1. adminpack — pgAdmin support toolpack

adminpack provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to database superusers by default, but may be allowed to other users by using the GRANT command.

The functions shown in Table F.1 provide write access to files on the machine hosting the server. (See also the functions in Table 9.102, which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given privileges of one of the pg_read_server_files or pg_write_server_files roles, as appropriate for the function, but either a relative or absolute path is allowable.

Table F.1. adminpack Functions

Function Description
pg_catalog.pg_file_write (*filename* text, *data* text, *append* boolean) → bigint Writes, or appends to, a text file.
pg_catalog.pg_file_sync (*filename* text) → void Flushes a file or directory to disk.
pg_catalog.pg_file_rename (*oldname* text, *newname* text [, *archivename* text]) → boolean Renames a file.
pg_catalog.pg_file_unlink (*filename* text) → boolean Removes a file.
pg_catalog.pg_logdir_ls () → setof record Lists the log files in the log_directory directory.

pg_file_write writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

pg_file_sync fsyncs the specified file or directory named by *filename*. An error is thrown on failure (e.g., the specified file is not present). Note that data_sync_retry has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

pg_file_rename renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

pg_file_unlink removes the specified file. Returns true on success, false if the specified file is not present or the unlink() call fails; other cases throw errors.

pg_logdir_ls returns the start timestamps and path names of all the log files in the log_directory directory. The log_filename parameter must have its default setting (postgresql-%Y-%m-%d_%H%M%S.log) to use this function.

F.2. amcheck — tools to verify table and index consistency

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in "logical" order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See Section 41.16.3 for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function `verify_heapam` checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that `verify_heapam` relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute `amcheck` functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

> **Note**
>
> Using `amcheck` 1.1.1 is not recommended as the `bt_index_parent_check` function works incorrectly in that version.

F.2.1. Functions

```
bt_index_check(index regclass, heapallindexed boolean) returns void
bt_index_check(index regclass, heapallindexed boolean, checkunique boolean) returns void
```

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
               c.relname,
               c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
```

```
ORDER BY c.relpages DESC LIMIT 10;
 bt_index_check |             relname             | relpages
----------------+---------------------------------+----------
                | pg_depend_reference_index       |       43
                | pg_depend_depender_index        |       40
                | pg_proc_proname_args_nsp_index  |       31
                | pg_description_o_c_o_index      |       21
                | pg_attribute_relid_attnam_index |       14
                | pg_proc_oid_index               |       10
                | pg_attribute_relid_attnum_index |        9
                | pg_amproc_fam_proc_index        |        5
                | pg_amop_opr_fam_index           |        5
                | pg_amop_fam_strat_index         |        5
(10 rows)
```

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when *`heapallindexed`* is `true`. `bt_index_check` with three arguments verifies unique constraints when *`checkunique`* is `true`. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean) returns void`
`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean, checkunique boolean) returns void`

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the *`heapallindexed`* argument is `true`, the function verifies the presence of all heap tuples that should be found within the index. `bt_index_parent_check` with four arguments verifies unique constraints when *`checkunique`* is `true`. When the optional *`rootdescend`* argument is `true`, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when hot standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

Tip

bt_index_check and bt_index_parent_check both output log messages about the verification process at DEBUG1 and DEBUG2 severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive psql session before running a verification query will display messages about the progress of verification with a manageable level of detail.

`verify_heapam(relation regclass, on_error_stop boolean, check_toast boolean, skip text, startblock bigint, endblock bigint, blkno OUT bigint, offnum OUT integer, attnum OUT integer, msg OUT text) returns setof record`

Checks a table, sequence, or materialized view for structural corruption, where pages in the relation contain data that is invalidly formatted, and for logical corruption, where pages are structurally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

`on_error_stop`

If true, corruption checking stops at the end of the first block in which any corruptions are found.

Defaults to false.

`check_toast`

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it against toast values could conceivably crash the server, although in many cases this would just produce an error.

Defaults to false.

`skip`

If not `none`, corruption checking skips blocks that are marked as all-visible or all-frozen, as specified. Valid options are `all-visible`, `all-frozen` and `none`.

Defaults to `none`.

`startblock`

If specified, corruption checking begins at the specified block, skipping all previous blocks. It is an error to specify a *`startblock`* outside the range of blocks in the target table.

By default, checking begins at the first block.

`endblock`

If specified, corruption checking ends at the specified block, skipping all remaining blocks. It is an error to specify an *`endblock`* outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, `verify_heapam` returns a row with the following columns:

`blkno`

The number of the block containing the corrupt page.

`offnum`

The OffsetNumber of the corrupt tuple.

`attnum`

The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

`msg`

A message describing the problem detected.

F.2.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to B-Tree verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a "dummy" `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure "fingerprints" every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.2.3. Using `amcheck` Effectively

`amcheck` can be effective at detecting various types of failure modes that data checksums will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

  This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

  If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See Section 23.1 and Section 23.2 for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

  Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

  Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

  Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

  When *`heapallindexed`* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with data page checksums.

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in the main table which lack a corresponding entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, `verify_heapam` has been designed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to catalog tables is performed and could be problematic if the catalogs themselves are corrupted.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

F.2.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. pageinspect may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

F.3. aqo — cost-based query optimization

The aqo module is a Postgres Pro Enterprise extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, aqo improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

F.3.1. Description

The aqo module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query class. If the queries differ in their constants only, they belong to the same class. For each query class, aqo stores the cardinality quality, planning time, execution time, and execution statistics for machine learning. Based on this data, aqo builds a new query plan and uses it for the next query of the same class. aqo test runs have shown significant performance improvements for complex queries.

aqo saves all the learning data (aqo_data), queries (aqo_query_texts), query settings (aqo_queries), and query execution statistics (aqo_query_stat) to files. When aqo starts, it loads this data to shared memory. You can access aqo data through functions and views.

When aqo.advanced is on, and aqo is run in the `intelligent` or `learn` mode, a unique hash value, which is computed from the query tree, is assigned to each query class to identify it and separate the collected statistics. If `aqo.advanced` is off, the statistics for all untracked query classes is stored in a common query class with hash 0.

Each query class has an associated separate space, called *feature space*, in which the statistics for this query class is collected. This feature space is identified by a hash value (`fs`), which is usually the same as the query ID. Each feature space has associated *feature subspaces*, where the information about selectivity and cardinality for each query plan node is collected. Each subspace is also identified by a hash value (`fss`).

Query-specific optimization settings are stored in the aqo_queries view.

F.3.1.1. Limitations

aqo currently has the following limitations:

- Query optimization using the aqo module is not supported on standby.
- Query optimization with aqo does not work with queries that only have temporary objects.
- Query optimization with aqo does not work for queries that contain `IMMUTABLE` functions.
- aqo does not collect statistics on replicas because replicas are read-only. However, aqo may use query execution statistics from the primary if the replica is physical.
- `learn` and `intelligent` modes are not supposed to work for a whole cluster with queries having a dynamically generated structure because these modes store all query class IDs, which are different for all queries in such a workload. Dynamically generated constants are supported, however.

F.3.2. Installation and Setup

The aqo extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable aqo:

1. Add `aqo` to the shared_preload_libraries parameter in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'aqo'
   ```

   The `aqo` library must be preloaded at the server startup, since adaptive query optimization needs to be enabled per cluster.

2. Create the aqo extension using the following query:

   ```
   CREATE EXTENSION aqo;
   ```

Once the extension is created, you can start optimizing queries.

To disable aqo in the current database, run:

```
DROP EXTENSION aqo;
```

To disable aqo at the cluster level, run:

```
ALTER SYSTEM SET aqo.enable = off;
SELECT pg_reload_conf();
```

To remove all the aqo data including the collected statistics, call `aqo_reset()`: to remove the data from the current database, run:

```
SELECT aqo_reset();
```

to remove all the data from the aqo storage, run:

```
SELECT aqo_reset(NULL);
```

If you do not want aqo to be loaded at the server restart, remove the line

```
shared_preload_libraries = 'aqo'
```

from the `postgresql.conf` file.

> **Important**
>
> For smooth physical replication transferring aqo data from the primary to a replica, ensure that the same aqo versions are installed on both. You can have different aqo versions installed, but in this case, set aqo.wal_rw to `off` on both and anticipate no replication.

F.3.2.1. Configuration

aqo behavior mainly depends on the aqo.enable, aqo.mode and aqo.advanced configuration parameters. Their default values allow you to start learning in the aqo basic mode once you just set `aqo.enable` to `on`.

To dynamically change any of these parameters, for example, mode, in your current session, run the following command:

```
SET aqo.mode = 'mode';
```

where *mode* is the name of the operation mode to use.

F.3.3. Usage

F.3.3.1. Using aqo in a Basic Mode

By default, aqo.advanced is off. This sets a recommended, basic, mode, where statistics is collected for plan nodes (identified by `fss`), and the collected machine learning data is used to correct the cardinality error for all queries whose plan contains a certain plan node. Once you set aqo.enable to `on`, aqo starts learning. Execute queries that you need to optimize several times until the plan is good enough and change aqo.mode to `frozen`. To apply the machine learning data at the level of the server instance, run the following command:

```
ALTER SYSTEM SET aqo.mode = frozen;
ALTER SYSTEM SET aqo.enable = on;
SELECT pg_reload_conf();
```

The machine learning data will be applied not only to the queries on which aqo learned, but to all the queries whose plan contains the nodes for which the statistics was collected. For the machine learning data not affect other queries, set aqo.advanced to `on` and collect statistics for individual queries. See Section F.3.3.2 for details.

F.3.3.2. Choosing the Operation Mode for Advanced Query Optimization

If you often run queries of the same class, for example, your application limits the number of possible query classes, you can enable aqo.advanced and use the `intelligent` mode to improve planning for these queries. In this mode, aqo analyzes each query execution and stores statistics. Statistics on queries of different classes is stored separately. If performance is not improved after 50 iterations, the aqo extension falls back to the default query planner.

> **Note**
>
> You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the Section 14.1.

Since the `intelligent` mode tries to learn separately for different query classes, aqo may fail to provide performance improvements if queries in the workload are of multiple different classes or if the classes of the queries in the workload are constantly changing. For such workloads, reset the aqo extension to the `controlled` mode, or try to turn off `aqo.advanced`.

When `aqo.advanced` is on, in the `controlled` mode, aqo does not collect statistics for new query classes, so they will not be optimized, but for known query classes, aqo will continue collecting statistics and using optimized planning algorithms. So use the `controlled` mode only after aqo learned in the `learn` or `intelligent` mode.

After aqo has already learned, `controlled` is the mode recommended for production use. To make aqo run in this mode on your whole production cluster, run

```
ALTER SYSTEM SET aqo.mode = 'controlled';
SELECT pg_reload_conf();
```

When `aqo.advanced` is on, the `learn` mode collects statistics from all the executed queries and updates the data for query classes. This mode is similar to the `intelligent` mode, except that it does not provide intelligent tuning. This mode is not recommended to be used permanently for a whole cluster because it tries aqo optimizations for every query class, even for those that do not need it, and this may lead to an unnecessary computational overhead and cause performance degradation.

Use the `learn` mode with `aqo.advanced` turned off to handle workloads with dynamically generated query structures. Overall performance improvement is not guaranteed. As this mode lacks intelligent tuning, the performance for some queries may even decrease, but this mode is good for a dynamic workload and consumes less memory than the `intelligent` mode.

If you want to reduce the impact of aqo on query planning and execution, you can use it in the `frozen` mode. In this mode, aqo only reads the collected statistics, but does not collect any new data.

F.3.3.3. Fine-Tuning aqo

You must have superuser rights to access aqo views and configure advanced query settings.

You can view all the processed query classes and their corresponding hash values in the aqo_query_texts view:

```
SELECT * FROM aqo_query_texts;
```

To find out the class, that is, hash, of a query and aqo mode, enable `aqo.show_hash (boolean)` (boolean) and `aqo.show_details (boolean)` (boolean) environment variables and execute the query. The output will contain something like this:

```
...
Planning Time: 23.538 ms
...
```

```
Execution Time: 249813.875 ms
...
Using aqo: true
AQO mode: LEARN
AQO advanced: OFF
...
Query hash: -2439501042637610315
```

Each query class has its own optimization settings. These settings are shown in the aqo_queries view:

```
SELECT * FROM aqo_queries;
```

You can manually change these settings to adjust the optimization for a particular query class. For example:

```
 -- Add a new query class to the aqo_queries view:

SET aqo.advanced='on';
SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';

 -- Disable auto_tuning, enable both learn_aqo and use_aqo
 -- for this query class:

SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, true, true, false)
  WHERE queryid = (SELECT queryid FROM aqo_query_texts
  WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');

 -- Run EXPLAIN ANALYZE while the plan changes:

EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;

 -- Disable learning to stop statistics collection
 -- and use the optimized plan:

SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, false, true, false)
  WHERE queryid = (SELECT queryid FROM aqo_query_texts
  WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

To stop intelligent tuning for a particular query class, disable the `auto_tuning` setting:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, NULL, NULL, false)
  WHERE queryid = 'hash';
```

where *`hash`* is the hash value for this query class. As a result, aqo disables automatic change of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query class, use the following command:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, false, NULL, false)
  WHERE queryid = 'hash';
```

where *`hash`* is the hash value for this query class.

To fully disable aqo for all queries and use the default Postgres Pro query planner, run:

```
SELECT count(*) FROM aqo_queries,
```

```
  LATERAL aqo_disable_class(queryid, NULL)
  WHERE queryid <> 0;
```

To disable aqo for all queries temporarily in the current session or for the whole cluster, but not remove or change the collected statistics and settings, turn off aqo.enable:

```
SET aqo.enable = 'off';
```

or

```
ALTER SYSTEM SET aqo.enable = 'off'
```

F.3.3.4. Sandbox Mode

You can experiment with aqo without touching its main knowledge base. To do this, execute the command

```
SET aqo.sandbox = ON;
```

This turns on the *sandbox mode*, which means that aqo will work in the isolated environment. However, if you turn on aqo.sandbox in different SQL sessions, they will use the same data.

Data obtained in the sandbox mode does not get replicated. But the sandbox mode can be used on a standby. Moreover, the only way to train aqo on a standby is turning on the sandbox mode when the replication is turned on, that is, `aqo.wal_rw` is true. Without the sandbox mode, aqo will work on the standby as if `aqo.mode` = `FROZEN`, that is, it will be able to use the existing knowledge base, but not update or extend it.

F.3.4. Reference

F.3.4.1. Configuration Parameters

`aqo.enable` (`boolean`)

Defines the state of aqo. If set to `off` aqo does not work except when aqo.force_collect_stat = `on`.

Default: `off`.

`aqo.mode` (`text`)

Sets the aqo operation mode. Defines how aqo handles new queries. Possible values:

- `intelligent` — saves new queries with `auto_tuning` enabled. See the description of the aqo_queries view for more details. May disable aqo for a query in the case of average performance reduction. Only works in this way if aqo.advanced = `on`, otherwise, this mode works exactly like `learn`.
- `learn` — collects statistics on all the executed queries, learns and makes predictions based on these statistics.
- `controlled` — only learns and makes predictions for known queries.
- `frozen` — makes predictions for known queries, but does not learn from any queries.

Default: `learn`.

`aqo.advanced` (`boolean`)

Enables the advanced learning routine, which saves separate learning statistics for each query class. Also allows fine-tuning the `use_aqo` and `learn_aqo` settings in the aqo_queries view. Fine-tuned query settings in the `aqo_query` view continue to work if `aqo.advanced` is disabled.

Default: `off`.

`aqo.force_collect_stat` (`boolean`)

Collects statistics on query executions in all aqo modes and even if `aqo.enable` is off.

Default: `off`.

`aqo.show_details` (`boolean`)

Adds some details to `EXPLAIN` output of a query, such as the prediction or feature-subspace hash, and shows some additional aqo-specific on-screen information.

Default: `on`.

`aqo.show_hash` (`boolean`)

Shows a hash value that uniquely identifies the class of queries or class of plan nodes. aqo uses the native query ID to identify a query class for consistency with other extensions, such as pg_stat_statements. So, the query ID can be taken from the `Query hash` field in `EXPLAIN ANALYZE` output of a query.

Default: `on`.

`aqo.join_threshold` (`integer`)

Ignores queries that contain smaller number of joins, which means that statistics for such queries is not collected.

Default: `0` (no queries are ignored).

`aqo.learn_statement_timeout` (`boolean`)

Learns on a plan interrupted by the statement timeout.

Default: `off`.

`aqo.statement_timeout` (`integer`)

Defines the initial value of the *smart statement timeout*, in milliseconds, which is needed to limit the execution time when manually training aqo on special queries with a poor cardinality forecast. aqo can dynamically change the value of the smart statement timeout during this training. When the cardinality estimation error on nodes exceeds 0.1, the value of `aqo.statement_timeout` is automatically incremented exponentially, but remains not greater than statement_timeout.

Default: `0`.

`aqo.wide_search` (`boolean`)

Enables searching neighbors with the same feature subspace among different query classes. Only has an effect if aqo.advanced = `on`.

Default: `off`.

`aqo.min_neighbors_for_predicting` (`integer`)

Defines how many samples collected in previous executions of the query will be used to predict the cardinality next time. If there are fewer of them, aqo will not make any prediction. A too large value may affect performance, but a too small value may reduce the prediction quality.

Default: `3`.

`aqo.predict_with_few_neighbors` (`boolean`)

Enables aqo to make predictions with fewer neighbors than specified by aqo.min_neighbors_for_predicting. When set to `off`, then aqo learns, but does not make predictions until the execution count for the query with different constants reaches 3 (default for `aqo.min_neighbors_for_predicting`).

Default: `on`.

`aqo.fs_max_items` (`integer`)

Defines the maximum number of feature spaces that aqo can operate with. When this number is exceeded, learning on new query classes will no longer occur, and they will not appear in the views accordingly. This parameter can only be set at server start.

Default: 10000.

aqo.fss_max_items (integer)

Defines the maximum number of feature subspaces that aqo can operate with. When this number is exceeded, the selectivity and cardinality for new query plan nodes will no longer be collected, and new feature subspaces will not appear in the aqo_data view accordingly. This parameter can only be set at server start.

Default: 100000.

aqo.querytext_max_size (integer)

Defines the maximum size of the query in the aqo_query_texts view. This parameter can only be set at server start.

Default: 1000.

aqo.dsm_size_max (integer)

Defines the maximum size of dynamic shared memory, in MB, that aqo can allocate to store learning data and query texts. If set to a number that is less than the size of the saved aqo data, the server will not start. This parameter can only be set at server start.

Default: 100.

aqo.wal_rw (boolean)

Enables physical replication and allows complete aqo data recovery after failure. When set to off on the primary, no data is transferred from it to a replica. When set to off on a replica, any data transferred from the primary is ignored. With this value, when the server fails, data can only be restored as of the last checkpoint. This parameter can only be set at server start.

Default: on.

aqo.sandbox (boolean)

Enables reserving a separate memory area in shared memory to be used by a primary or standby node, which allows collecting and using statistics with the data in this memory area. If enabled on the primary, the extension uses the separate shared memory area that is not replicated to the standby. Changing the value of this parameter resets the aqo cache. Only superusers can change this setting.

Default: off.

F.3.4.2. Views

F.3.4.2.1. aqo_query_texts

The aqo_query_texts view classifies all the query classes processed by aqo. For each query class, the view shows the text of the first analyzed query of this class.

Table F.2. aqo_query_texts View

Column Name	Description
queryid	The unique identifier of the query class.
dbid	The identifier of the database.
query_text	Text of the first analyzed query of the given class. The query text length is limited by aqo.querytext_max_size.

F.3.4.2.2. aqo_queries

The aqo_queries view shows optimization settings for different query classes. One query executed in two different databases is stored twice although the queryid is the same.

Table F.3. aqo_queries View

Setting	Description
queryid	The unique identifier of the query class.
dbid	The identifier of the database in which the query was executed.
fs	The unique identifier (hash) of the feature space in which the statistics for this query class is collected. Defaults to queryid. You can manually set fs to the same value for different query classes, especially for similar queries.
learn_aqo	Shows whether statistics collection for this query class is enabled.
use_aqo	Shows whether the aqo cardinality prediction for the next execution of this query class is enabled.
auto_tuning	Shows whether aqo can dynamically change use_aqo and learn_aqo settings for this query class. By default, set to true for new queries if aqo.advanced is on and aqo.mode = intelligent. When auto_tuning is on, if for several successive executions of a query for which use_aqo is off, the cardinality error remains sufficiently small and stable, aqo turns on use_aqo . For queries with learn_aqo =true (it is so for new queries), several first executions are done both using aqo and without it. The faster the query is executed compared to the execution with the standard planner, the more likely aqo will be used for the next query execution. If after a certain number of executions the execution time with aqo appears to be worse than with the standard planner, aqo will never be used for this query class: auto_tuning , use_aqo and learn_aqo are set to off.
smart_timeout	The value of the smart statement timeout for this query class. The initial value of the smart statement timeout for any query is defined by the statement_timeout configuration parameter.
count_increase_timeout	Shows how many times the smart statement timeout increased for this query class.

F.3.4.2.3. aqo_data

The aqo_data view shows machine learning data for cardinality estimation refinement. The number of rows is limited by aqo.fss_max_items. To discard all the collected statistics for a particular query class, you can delete all rows from aqo_data with the corresponding fs.

Table F.4. aqo_data View

Data	Description
fs	The identifier (hash) of the feature space.
fss	The identifier (hash) of the feature subspace.
dbid	The identifier of the database.

Data	Description
nfeatures	Feature-subspace size for the query plan node.
features	Logarithm of the selectivity which the cardinality prediction is based on.
targets	Cardinality logarithm for the query plan node.
reliability	Confidence level of the learning statistics. Equals: • 1 (default) — indicates data obtained after normal execution of a query • 0.1 — indicates data obtained from a partially executed node (not needed as unreliable) • 0.9 — indicates data obtained from a finished node, but from a partially executed statement
oids	List of IDs of tables that were involved in the prediction for this node.

F.3.4.2.4. aqo_query_stat

The aqo_query_stat view shows statistics on query execution, by query class. aqo uses this data when auto_tuning is enabled for a particular query class.

Table F.5. aqo_query_stat View

Data	Description
queryid	The unique identifier of the query class.
dbid	The identifier of the database.
execution_time_with_aqo	Array of execution times for queries run with aqo enabled.
execution_time_without_aqo	Array of execution times for queries run with aqo disabled.
planning_time_with_aqo	Array of planning times for queries run with aqo enabled.
planning_time_without_aqo	Array of planning times for queries run with aqo disabled.
cardinality_error_with_aqo	Array of cardinality estimation errors in the selected query plans with aqo enabled.
cardinality_error_without_aqo	Array of cardinality estimation errors in the selected query plans with aqo disabled.
executions_with_aqo	Number of queries run with aqo enabled.
executions_without_aqo	Number of queries run with aqo disabled.

F.3.4.3. Functions

aqo adds several functions to Postgres Pro catalog.

F.3.4.3.1. Storage Management Functions

> **Important**
>
> Functions aqo_queries_update, aqo_query_texts_update, aqo_query_stat_update, aqo_data_update and aqo_data_delete modify data files underlying aqo views. Therefore, call these functions only if you understand the logic of adaptive query optimization.

`aqo_cleanup()` → `setof integer`

Removes data related to query classes that are linked (may be partially) with removed relations. Returns the number of removed feature spaces (classes) and feature subspaces. Insensitive to removing other objects.

`aqo_enable_class` (*queryid* `bigint`, *dbid* `oid`) → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the `intelligent` mode) to true for the query class with the specified *queryid* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database.

`aqo_disable_class` (*queryid* `bigint`, *dbid* `oid`) → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` to false for the query class with the specified *queryid* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database.

`aqo_drop_class` (*queryid* `bigint`, *dbid* `oid`) → `integer`

Removes all data related to the specified query class and database from the aqo storage. You can set *dbid* to NULL instead of the ID of the current database. Returns the number of records removed from the aqo storage.

`aqo_reset` (*dbid* `oid`) → `bigint`

Removes records from the specified database: machine learning data, query texts, statistics and query class preferences. If *dbid* is omitted, removes the data from the current database. If *dbid* is NULL, removes all records from the aqo storage. Returns the number of records removed.

`aqo_queries_update` (*queryid* `bigint`, *dbid* `oid`, *fs* `bigint`, *learn_aqo* `boolean`, *use_aqo* `boolean`, *auto_tuning* `boolean`) → `boolean`

Updates or inserts a record in a data file underlying the aqo_queries view for the specified *queryid* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. NULL values for parameters being set mean leave them as is. Note that records with a zero value of *queryid* or *dbid* cannot be updated. Returns `false` in case of error, `true` otherwise.

`aqo_query_texts_update` (*queryid* `bigint`, *dbid* `oid`, *query_text* `text`) → `boolean`

Updates or inserts a record in a data file underlying the aqo_query_texts view for the specified *queryid* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. Note that records with a zero value of *queryid* or *dbid* cannot be updated. Returns `false` in case of error, `true` otherwise.

`aqo_query_stat_update` (*queryid* `bigint`, *dbid* `oid`, *execution_time_with_aqo* `double precision[]`, *execution_time_without_aqo* `double precision[]`, *planning_time_with_aqo* `double precision[]`, *planning_time_without_aqo* `double precision[]`, *cardinality_error_with_aqo* `double precision[]`, *cardinality_error_without_aqo* `double precision[]`, *executions_with_aqo* `bigint[]`, *executions_without_aqo* `bigint[]`) → `boolean`

Updates or inserts a record in a data file underlying the aqo_query_stat view for the specified *queryid* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. Returns `false` in case of error, `true` otherwise.

`aqo_data_update` (*fs* `bigint`, *fss* `integer`, *dbid* `oid`, *nfeatures* `integer`, *features* `double precision[][]`, *targets* `double precision[]`, *reliability* `double precision[]`, *oids* `oid[]`) → `boolean`

Updates or inserts a record in a data file underlying the aqo_data view for the specified *fs*, *fss* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. Returns `false` in case of error, `true` otherwise.

`aqo_data_delete` (*`fs`* `bigint`, *`fss`* `integer`, *`dbid`* `oid`) → `boolean`

Removes a record from a data file underlying the aqo_data view for the specified *`fs`*, *`fss`* and *`dbid`*. You can set *`dbid`* to NULL instead of the ID of the current database. Returns `false` in case of error, `true` otherwise.

F.3.4.3.2. Memory Management Functions

`aqo_memory_usage` () → `setof record`

Shows allocated and used sizes of aqo memory contexts and hash tables. Returns a table:

`name`

Short description of the memory context or hash table

`allocated_size`

Total size of the allocated memory

`used_size`

Size of the currently used memory

F.3.4.3.3. Functions for Analytics

`aqo_cardinality_error` (*`controlled`* `boolean`) → `setof record`

Shows the cardinality error for the last execution of queries. If *`controlled`* is true, shows queries executed with aqo enabled. If *`controlled`* is false, shows queries that were executed with aqo disabled, but that have collected aqo statistics. Returns a table:

`num`

Sequential number

`queryid`

The unique identifier of the query class

`dbid`

The identifier of the database

`fs`

The identifier of the feature space, usually zero or `queryid`

`error`

aqo error calculated on query plan nodes

`nexecs`

Number of executions of queries associated with this `queryid`

`aqo_execution_time` (*`controlled`* `boolean`) → `setof record`

Shows the execution time for queries. If *`controlled`* is true, shows the execution time of the last execution with aqo enabled. If *`controlled`* is false, returns the average execution time for all logged executions with aqo disabled. Execution time without aqo can be collected when aqo.mode = `intelligent` or aqo.force_collect_stat = `on`. Returns a table:

`num`

Sequential number

`queryid`

The unique identifier of the query class

`dbid`

The identifier of the database

`fs`

The identifier of the feature space, usually zero or `queryid`

`exec_time`

If *`controlled`* = true, last query execution time with aqo, otherwise, average execution time for all executions without aqo

`nexecs`

Number of executions of queries associated with this `queryid`

F.3.5. Examples

Example F.1. Learning on a Query (Basic Mode)

Consider optimization of a query using aqo.

When the query is executed for the first time, it is missing in tables underlying aqo views. So there is no data for predicting with aqo for each plan node, and "AQO not used" lines appear in the `EXPLAIN` output:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';
                                                                  QUERY PLAN

 Query hash: 402936317627943257
 JOINS: 2
(23 rows)
```

If there is no information on a certain node in the aqo_data view, aqo will add the appropriate record there for future learning and predictions except for nodes with `fss=0` in the `EXPLAIN` output. As each of `features` and `targets` in the `aqo_data` view is a logarithm to base `e`, to get the actual value, raise `e` to this power. For example: exp(7.703007682479236):

```
 demo=# select * from aqo_data;
 fs |         fss          | dbid  | nfeatures |                    features
      |       targets        | reliability |        oids
----+----------------------+-------+-----------
+-----------------------------------------------+----------------------+-------------
+---------------------
   0 |  1362775811343989307 | 16429 |         0 |
       | {14.454357295615447} | {1}         | {16452}
   0 | -6410966714754547713 | 16429 |         0 |
       | {14.674314116080508} | {1}         | {16479}
   0 | -1289471166524579716 | 16429 |         1 | {{-1.3775704575284085}}
       | {9.701371368413994}  | {1}         | {16458}
   0 |  8598194613120045129 | 16429 |         2 |
 {{-13.492416828684513,-1.3775704575284085}} | {7.703007682479236}  | {1}         |
 {16479,16458,16452}
   0 | -7651474063207585780 | 16429 |         2 |
 {{-11.092306109090387,-1.3775704575284085}} | {13.056768298305919} | {1}         |
 {16479,16458}
(5 rows)
```

When the query is executed for the second time, aqo recognizes the query and makes a prediction. Pay attention to the cardinality predicted by aqo and the value of aqo error (“error=0%”).

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id

```

```
(23 rows)
```

However, instead of recalculating `features` and `targets`, aqo added new values of selectivity and cardinality for this query to `aqo_data`:

```
demo=# select * from aqo_data;
 fs |         fss          | dbid  | nfeatures |
 features                                        |                 targets
    | reliability |        oids

----+----------------------+-------+-----------
+-------------------------------------------------------------------------------------------
+-----------------------------------------+-------------+------------
---------
  0 |  1362775811343989307 | 16429 |         0 |
                                                  | {14.454357295615447}
   | {1}         | {16452}
  0 | -6410966714754547713 | 16429 |         0 |
                                                  | {14.674314116080508}
   | {1}         | {16479}
  0 | -1289471166524579716 | 16429 |         1 | {{-1.3775704575284085},
{-1.2287385463463019}}                                                    |
 {9.701371368413994,9.854297308345357}   | {1,1}       | {16458}
  0 |  8598194613120045129 | 16429 |         2 |
 {{-13.492416828684513,-1.3775704575284085},{-13.492416828684513,-1.2287385463463019}}
 | {7.703007682479236,11.620855676130656}  | {1,1}       | {16479,1645
8,16452}
  0 | -7651474063207585780 | 16429 |         2 |
 {{-11.092306109090387,-1.3775704575284085},{-11.092306109090387,-1.2287385463463019}}
 | {13.056768298305919,13.266354624518149} | {1,1}       | {16479,1645
8}
(5 rows)
```

Now the prediction has a small error of about 3%, which can be explained by a calculation error:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id

Example F.2. Using the aqo_query_stat View

The aqo_query_stats view shows statistics on the query planning time, query execution time and cardinality error. Based on this data you can make a decision whether to use aqo predictions for different query classes.

Let's query the aqo_query_stats view:

```
demo=# SELECT * FROM aqo_query_stat \gx
-[ RECORD 1 ]-----------------
+-------------------------------------------------------------
queryid                       | 7809046947949890015
dbid                          | 16429
execution_time_with_aqo       | {1.039218233,0.925258453,0.831166925,0.779602353}
execution_time_without_aqo    | {1.022052611,0.936486619}
planning_time_with_aqo        | {0.003305339,0.002129048,0.002538877,0.002142972}
planning_time_without_aqo     | {0.000767553,0.000711208}
cardinality_error_with_aqo    |
 {0.4854215265638894,0,1.1711726076352047,0.007732205169478082}
cardinality_error_without_aqo | {0.4854215265638894,1.571562511977072}
executions_with_aqo           | 4
executions_without_aqo        | 2
```

The retrieved data is for the query from Example F.1, which was executed once without aqo for each of the parameters f.scheduled_departure > '2017-08-10 15:00:00+00' and f.scheduled_departure > '2017-08-15 15:00:00+00' and twice with aqo for each of these parameters. It is clear that with aqo, the cardinality error decreases to 0.0077, while the minimum cardinality error without aqo is 0.4854. Besides, the execution time with aqo is lower than without it. So the conclusion is that aqo learns well on this query, and the prediction can be used for this query class.

Example F.3. Using aqo in the Advanced Mode

The advanced mode allows a more flexible control over aqo. When this mode is activated, that is,

```
demo=# SET aqo.advanced = on;
```

aqo will collect the machine learning data separately for each query executed. For example:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';
                                                          QUERY PLAN
-------------------------------------------------------------------------------------------------------------
 Hash Join  (cost=63796.33..140286.73 rows=477728 width=25) (actual rows=2215 loops=1)
   AQO not used, fss=8598194613120045129
   Hash Cond: ((bp.flight_id = f.flight_id) AND (bp.ticket_no = tf.ticket_no))
   ->  Seq Scan on boarding_passes bp  (cost=0.00..32894.95 rows=1894295 width=25)
 (actual rows=1894295 loops=1)
         AQO not used, fss=1362775811343989307
```

```
   ->  Hash  (cost=51379.43..51379.43 rows=595260 width=22) (actual rows=468255
 loops=1)
         Buckets: 131072  Batches: 8  Memory Usage: 4223kB
         ->  Hash Join  (cost=1859.80..51379.43 rows=595260 width=22) (actual
 rows=468255 loops=1)
               AQO not used, fss=-7651474063207585780
               Hash Cond: (tf.flight_id = f.flight_id)
               ->  Seq Scan on ticket_flights tf  (cost=0.00..43323.35 rows=2360335
 width=18) (actual rows=2360335 loops=1)
                     AQO not used, fss=-6410966714754547713
               ->  Hash  (cost=1652.80..1652.80 rows=16560 width=4) (actual rows=16340
 loops=1)
                     Buckets: 32768  Batches: 1  Memory Usage: 831kB
                     ->  Seq Scan on flights f  (cost=0.00..1652.80 rows=16560 width=4)
 (actual rows=16340 loops=1)
                           AQO not used, fss=-1289471166524579716
                           Filter: (scheduled_departure > '2017-08-15
 22:00:00+07'::timestamp with time zone)
                           Rows Removed by Filter: 49324
 Using aqo: true
 AQO mode: LEARN
 AQO advanced: ON
 Query hash: 402936317627943257
 JOINS: 2
(23 rows)
```

Now this query is stored in aqo_data with a non-zero `fs` (`fs` is equal to the query hash by default):

```
demo=# SELECT * FROM aqo_data;
         fs         |         fss          | dbid  | nfeatures |
 features                   |       targets        | reliability |        oids
--------------------+----------------------+-------+-----------
+-------------------------------------------+----------------------+-------------
+---------------------
 402936317627943257 | -6410966714754547713 | 16429 |         0 |
                    | {14.674314116080508} | {1}         | {16479}
 402936317627943257 |  1362775811343989307 | 16429 |         0 |
                    | {14.454357295615447} | {1}         | {16452}
 402936317627943257 | -1289471166524579716 | 16429 |         1 |
 {{-1.3775704575284085}}                    | {9.701371368413994}  | {1}         |
 {16458}
 402936317627943257 |  8598194613120045129 | 16429 |         2 |
 {{-13.492416828684513,-1.3775704575284085}} | {7.703007682479236}  | {1}         |
 {16479,16458,16452}
 402936317627943257 | -7651474063207585780 | 16429 |         2 |
 {{-11.092306109090387,-1.3775704575284085}} | {13.056768298305919} | {1}         |
 {16479,16458}
(5 rows)
```

We can make a few settings individually for this query. These are values of `learn_aqo`, `use_aqo` and `auto_tuning` in the aqo_queries view:

```
demo=# SELECT * FROM aqo_queries;
      queryid       | dbid  |         fs         | learn_aqo | use_aqo | auto_tuning |
 smart_timeout | count_increase_timeout
--------------------+-------+--------------------+-----------+---------+-------------
+---------------+-----------------------
 402936317627943257 | 16429 | 402936317627943257 | t         | t       | f           |
             0 |                     0
```

```
                  0 |     0 |                   0 | f         | f       | f           |
           0 |                       0
(2 rows)
```

Let's set `use_aqo` to `false`:

```
demo=# SELECT aqo_queries_update(402936317627943257, NULL, NULL, NULL, false, NULL);
 aqo_queries_update
--------------------
 t
(1 row)
```

Now we change a constant in the query:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-10 15:00:00+00';
                                                                  QUERY PLAN
-----------------------------------------------------------------------------------------------

                           Buckets: 16384  Batches: 1  Memory Usage: 703kB
                           ->  Seq Scan on flights f  (cost=0.00..1652.80 rows=16340
 width=4) (actual rows=16340 loops=1)
                                 AQO: rows=16340, error=0%, fss=-1289471166524579716
                                 Filter: (scheduled_departure > '2017-08-15
 22:00:00+07'::timestamp with time zone)
```

```
                                    Rows Removed by Filter: 49324
   ->  Index Scan using tickets_pkey on tickets t  (cost=0.42..0.48 rows=1 width=104)
 (actual rows=1 loops=2215)
         AQO not used, fss=2731022528523952664
         Index Cond: (ticket_no = bp.ticket_no)
 Using aqo: true
 AQO mode: LEARN
 AQO advanced: ON
 Query hash: 7809046947949890015
 JOINS: 3
(28 rows)
```

Example F.4. Using the Sandbox Mode

```
SET aqo.sandbox = ON;
SET aqo.enable = ON;
SET aqo.advanced = OFF;
-- Clean up the sandbox knowledge base without touching the main data
SELECT aqo_reset();

EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT t.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
JOIN tickets t ON t.ticket_no = tf.ticket_no
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';

-- Be executing the previous query until plans get stabilized
...

-- Copy data obtained with aqo.advanced = OFF from sandbox
CREATE TABLE aqo_data_sandbox AS SELECT * FROM aqo_data;
SET aqo.sandbox = OFF;
SELECT aqo_data_update (fs, fss, dbid, nfeatures, features, targets, reliability, oids)
FROM aqo_data_sandbox WHERE fs = 0;
DROP TABLE aqo_data_sandbox;
```

Oleg Ivanov

F.4. auth_delay — pause on authentication failure

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via shared_preload_libraries in `postgresql.conf`.

F.4.1. Configuration Parameters

`auth_delay.milliseconds` (`integer`)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

F.4.2. Author

KaiGai Kohei `<kaigai@ak.jp.nec.com>`

F.5. auto_explain — log execution plans of slow queries

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run EXPLAIN by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in session_preload_libraries or shared_preload_libraries in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.5.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration` (`integer`)

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to `0` logs all plans. `-1` (the default) disables logging of plans. For example, if you set it to `250ms` then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_parameter_max_length` (`integer`)

`auto_explain.log_parameter_max_length` controls the logging of query parameter values. A value of `-1` (the default) logs the parameter values in full. `0` disables logging of parameter values. A value greater than zero truncates each parameter value to that many bytes. Only superusers can change this setting.

`auto_explain.log_analyze` (`boolean`)

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

> **Note**
>
> When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers` (`boolean`)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal` (`boolean`)

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (`boolean`)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (`boolean`)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (`boolean`)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings` (`boolean`)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (`enum`)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is text. Only superusers can change this setting.

`auto_explain.log_level` (`enum`)

`auto_explain.log_level` selects the log level at which auto_explain will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (`boolean`)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (`real`)

`auto_explain.sample_rate` causes auto_explain to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

F.5.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
```

```
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms planning: 0.548 ms plan:
  Query Text: SELECT count(*)
              FROM pg_class, pg_index
              WHERE oid = indrelid AND indisunique;
  Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
 loops=1)
    ->  Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
 loops=1)
          Hash Cond: (pg_class.oid = pg_index.indrelid)
          ->  Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
 time=0.016..0.140 rows=255 loops=1)
          ->  Hash  (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
 loops=1)
                Buckets: 1024  Batches: 1  Memory Usage: 4kB
                ->  Seq Scan on pg_index  (cost=0.00..3.02 rows=92 width=4) (actual
 time=0.008..3.187 rows=92 loops=1)
                      Filter: indisunique
```

Note that Postgres Pro added a new field to the output to show planning time.

F.6. basebackup_to_shell — example "shell" pg_basebackup module

`basebackup_to_shell` adds a custom basebackup target called `shell`. This makes it possible to run `pg_basebackup --target=shell` or, depending on how this module is configured, `pg_basebackup --target=shell:`*`DETAIL_STRING`*, and cause a server command chosen by the server administrator to be executed for each tar archive generated by the backup process. The command will receive the contents of the archive via standard input.

This module is primarily intended as an example of how to create a new backup targets via an extension module, but in some scenarios it may be useful for its own sake. In order to function, this module must be loaded via shared_preload_libraries or local_preload_libraries.

F.6.1. Configuration Parameters

`basebackup_to_shell.command` (`string`)

The command which the server should execute for each archive generated by the backup process. If `%f` occurs in the command string, it will be replaced by the name of the archive (e.g. `base.tar`). If `%d` occurs in the command string, it will be replaced by the target detail provided by the user. A target detail is required if `%d` is used in the command string, and prohibited otherwise. For security reasons, it may contain only alphanumeric characters. If `%%` occurs in the command string, it will be replaced by a single `%`. If `%` occurs in the command string followed by any other character or at the end of the string, an error occurs.

`basebackup_to_shell.required_role` (`string`)

The role required in order to make use of the `shell` backup target. If this is not set, any replication user may make use of the `shell` backup target.

F.6.2. Author

Robert Haas `<rhaas@postgresql.org>`

F.7. basic_archive — an example WAL archive module

basic_archive is an example of an archive module. This module copies completed WAL segment files to the specified directory. This may not be especially useful, but it can serve as a starting point for developing your own archive module. For more information about archive modules, see Chapter 54.

In order to function, this module must be loaded via archive_library, and archive_mode must be enabled.

F.7.1. Configuration Parameters

basic_archive.archive_directory (string)

The directory where the server should copy WAL segment files. This directory must already exist. The default is an empty string, which effectively halts WAL archiving, but if archive_mode is enabled, the server will accumulate WAL segment files in the expectation that a value will soon be provided.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
archive_mode = 'on'
archive_library = 'basic_archive'
basic_archive.archive_directory = '/path/to/archive/directory'
```

F.7.2. Notes

Server crashes may leave temporary files with the prefix archtemp in the archive directory. It is recommended to delete such files before restarting the server after a crash. It is safe to remove such files while the server is running as long as they are unrelated to any archiving still in progress, but users should use extra caution when doing so.

F.7.3. Author

Nathan Bossart

F.8. biha — built-in high-availability cluster

biha is a Postgres Pro extension that allows managing a BiHA cluster — a cluster with physical replication and built-in failover, high availability, and automatic node failure recovery. For more information about the BiHA solution and using the biha extension, see Built-in High Availability (BiHA).

F.9. bloom — bloom filter index access method

bloom provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.9.1. Parameters

A bloom index accepts the following parameters in its WITH clause:

length

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

col1 — col32

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.9.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
       WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes i1 and i2 mapped to 2 bits, and attribute i3 mapped to 4 bits. We could have omitted the length, col1, and col2 specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
   SELECT
     (random() * 1000000)::int as i1,
     (random() * 1000000)::int as i2,
     (random() * 1000000)::int as i3,
     (random() * 1000000)::int as i4,
     (random() * 1000000)::int as i5,
     (random() * 1000000)::int as i6
   FROM
  generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

```
                                                    QUERY PLAN
-------------------------------------------------------------------
---------------------------------
 Seq Scan on tbloom  (cost=0.00..213744.00 rows=250 width=24) (actual
 time=357.059..357.059 rows=0 loops=1)
   Filter: ((i2 = 898732) AND (i5 = 123451))
   Rows Removed by Filter: 10000000
 Planning Time: 0.346 ms
 Execution Time: 357.076 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
 pg_size_pretty
----------------
 386 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                                    QUERY PLAN
-------------------------------------------------------------------
---------------------------------
 Seq Scan on tbloom  (cost=0.00..213744.00 rows=2 width=24) (actual
 time=351.016..351.017 rows=0 loops=1)
   Filter: ((i2 = 898732) AND (i5 = 123451))
   Rows Removed by Filter: 10000000
 Planning Time: 0.138 ms
 Execution Time: 351.035 ms
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
 pg_size_pretty
----------------
 153 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                                      QUERY PLAN
-------------------------------------------------------------------
-------------------------------------------------
 Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24) (actual
 time=22.605..22.606 rows=0 loops=1)
   Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
   Rows Removed by Index Recheck: 2300
   Heap Blocks: exact=2256
   ->  Bitmap Index Scan on bloomidx  (cost=0.00..178436.00 rows=1 width=0) (actual
 time=20.005..20.005 rows=2300 loops=1)
         Index Cond: ((i2 = 898732) AND (i5 = 123451))
 Planning Time: 0.099 ms
 Execution Time: 22.632 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                                          QUERY PLAN
------------------------------------------------------------------------------
-------------------------------------------------------
 Bitmap Heap Scan on tbloom  (cost=9.29..13.30 rows=1 width=24) (actual
 time=0.032..0.033 rows=0 loops=1)
   Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
   ->  BitmapAnd  (cost=9.29..9.29 rows=1 width=0) (actual time=0.047..0.047 rows=0
 loops=1)
         ->  Bitmap Index Scan on btreeidx5  (cost=0.00..4.52 rows=11 width=0) (actual
 time=0.026..0.026 rows=7 loops=1)
               Index Cond: (i5 = 123451)
         ->  Bitmap Index Scan on btreeidx2  (cost=0.00..4.52 rows=11 width=0) (actual
 time=0.007..0.007 rows=8 loops=1)
               Index Cond: (i2 = 898732)
 Planning Time: 0.264 ms
 Execution Time: 0.047 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 88.5 MB, so the total space needed is 531 MB, over three times the space used by the bloom index.

F.9.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR    1   =(text, text),
    FUNCTION    1   hashtext(text);
```

F.9.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

F.9.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.10. btree_gin — GIN operator classes with B-tree behavior

btree_gin provides GIN operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, name, bool, bpchar, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.10.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.10.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See *http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin* for additional information.

F.11. btree_gist — GiST operator classes with B-tree behavior

btree_gist provides GiST index operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, numeric, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, char, varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, bool and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, btree_gist also provides index support for <> ("not equals"). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, btree_gist defines a distance operator <->, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time without time zone, date, interval, oid, and money.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.11.1. Example Usage

Simple example using btree_gist instead of btree:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
  cage   INTEGER,
  animal TEXT,
  EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"

```

F.11.2. Upgrade notes for version 1.6

In version 1.6 `btree_gist` switched to using in-core distance operators, and its own implementations were removed. References to these operators in `btree_gist` opclasses will be updated automatically during the extension upgrade, but if the user has created objects referencing these operators or functions, then these objects must be dropped manually before updating the extension.

F.11.3. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<janko.richter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See *http://www.sai.msu.su/~megera/postgres/gist/* for additional information.

F.12. citext — a case-insensitive character string type

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

> **Tip**
>
> Consider using *nondeterministic collations* (see Section 23.2.2.4) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.12.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.12.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (
    nick CITEXT PRIMARY KEY,
    pass TEXT   NOT NULL
);

INSERT INTO users VALUES ( 'larry',  sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Tom',    sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Damian', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'NEAL',   sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Bjørn',  sha256(random()::text::bytea) );

SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

F.12.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are citext-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators ~ and ~* exhibit the same behavior when applied to citext: they both match case-insensitively. The same is true for !~ and !~*, as well as for the LIKE operators ~~ and ~~*, and !~~ and !~~*. If you'd like to match case-sensitively, you can cast the operator's arguments to text.

Similarly, all of the following functions perform matching case-insensitively if their arguments are citext:

- regexp_match()
- regexp_matches()
- regexp_replace()
- regexp_split_to_array()
- regexp_split_to_table()
- replace()
- split_part()
- strpos()
- translate()

For the regexp functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to text before using one of these functions if you want case-sensitive behavior.

F.12.4. Limitations

- citext's case-folding behavior depends on the LC_CTYPE setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with citext's comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a COLLATE specification to citext columns or data values. Currently, citext operators will honor a non-default COLLATE specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's LC_CTYPE setting (that is, as though COLLATE "default" were given). This may be changed in a future release so that both steps follow the input COLLATE specification.
- citext is not as efficient as text because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only text can support B-Tree deduplication. However, citext is slightly more efficient than using lower to get case-insensitive matching.
- citext doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the text type and manually use the lower function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as citext and explicitly casting the column to text when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the citext operators must be in the current search_path (typically public); if it is not, the normal case-sensitive text operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode

distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

F.12.5. Author

David E. Wheeler `<david@kineticode.com>`

Inspired by the original `citext` module by Donald Fraser.

F.13. cube — a multi-dimensional cube data type

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered "trusted", that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.13.1. Syntax

Table F.6 shows the valid external representations for the `cube` type. *x*, *y*, etc. denote floating-point numbers.

Table F.6. Cube External Representations

External Syntax	Meaning
x	A one-dimensional point (or, zero-length one-dimensional interval)
(*x*)	Same as above
x1, *x2*,..., *xn*	A point in n-dimensional space, represented internally as a zero-volume cube
(*x1*, *x2*,..., *xn*)	Same as above
(*x*),(*y*)	A one-dimensional interval starting at *x* and ending at *y* or vice versa; the order does not matter
[(*x*),(*y*)]	Same as above
(*x1*,..., *xn*),(*y1*,..., *yn*)	An n-dimensional cube represented by a pair of its diagonally opposite corners
[(*x1*,..., *xn*),(*y1*,..., *yn*)]	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform "lower left — upper right" internal representation. When the corners coincide, `cube` stores only one corner along with an "is point" flag to avoid wasting space.

White space is ignored on input, so `[(x),(y)]` is the same as `[ ( x ), ( y ) ]`.

F.13.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.13.3. Usage

Table F.7 shows the specialized operators provided for type `cube`.

Table F.7. Cube Operators

Operator Description
`cube && cube → boolean` Do the cubes overlap?
`cube @> cube → boolean` Does the first cube contain the second?
`cube <@ cube → boolean` Is the first cube contained in the second?
`cube -> integer → float8` Extracts the *n*-th coordinate of the cube (counting from 1).

Operator Description
`cube ~> integer → float8` Extracts the *n*-th coordinate of the cube, counting in the following way: *n* = 2 * *k* - 1 means lower bound of *k*-th dimension, *n* = 2 * *k* means upper bound of *k*-th dimension. Negative *n* denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
`cube <-> cube → float8` Computes the Euclidean distance between the two cubes.
`cube <#> cube → float8` Computes the taxicab (L-1 metric) distance between the two cubes.
`cube <=> cube → float8` Computes the Chebyshev (L-inf metric) distance between the two cubes.

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a UNIQUE constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.8 shows the available functions.

Table F.8. Cube Functions

Function Description Example(s)
`cube ( float8 ) → cube` Makes a one dimensional cube with both coordinates the same. `cube(1)  → (1)`
`cube ( float8, float8 ) → cube` Makes a one dimensional cube. `cube(1, 2)  → (1),(2)`
`cube ( float8[] ) → cube` Makes a zero-volume cube using the coordinates defined by the array. `cube(ARRAY[1,2,3])  → (1, 2, 3)`
`cube ( float8[], float8[] ) → cube`

Function
Description
Example(s)

Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.

```
cube(ARRAY[1,2], ARRAY[3,4])      → (1, 2),(3, 4)
```

`cube ( cube, float8 ) → cube`

Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.

```
cube('(1,2),(3,4)'::cube, 5)         → (1, 2, 5),(3, 4, 5)
```

`cube ( cube, float8, float8 ) → cube`

Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.

```
cube('(1,2),(3,4)'::cube, 5, 6)          → (1, 2, 5),(3, 4, 6)
```

`cube_dim ( cube ) → integer`

Returns the number of dimensions of the cube.

```
cube_dim('(1,2),(3,4)')         → 2
```

`cube_ll_coord ( cube, integer ) → float8`

Returns the *n*-th coordinate value for the lower left corner of the cube.

```
cube_ll_coord('(1,2),(3,4)', 2)           → 2
```

`cube_ur_coord ( cube, integer ) → float8`

Returns the *n*-th coordinate value for the upper right corner of the cube.

```
cube_ur_coord('(1,2),(3,4)', 2)           → 4
```

`cube_is_point ( cube ) → boolean`

Returns true if the cube is a point, that is, the two defining corners are the same.

```
cube_is_point(cube(1,1))       → t
```

`cube_distance ( cube, cube ) → float8`

Returns the distance between two cubes. If both cubes are points, this is the normal distance function.

```
cube_distance('(1,2)', '(3,4)')         → 2.8284271247461903
```

`cube_subset ( cube, integer[] ) → cube`

Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.

```
cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[2])            → (3),(7)
cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[3,2,1,1])                → (5, 3,
1, 1),(8, 7, 6, 6)
```

`cube_union ( cube, cube ) → cube`

Produces the union of two cubes.

```
cube_union('(1,2)', '(3,4)')         → (1, 2),(3, 4)
```

`cube_inter ( cube, cube ) → cube`

Produces the intersection of two cubes.

```
cube_inter('(1,2)', '(3,4)')         → (3, 4),(1, 2)
```

`cube_enlarge ( c cube, r double, n integer ) → cube`

Increases the size of the cube by the specified radius *r* in at least *n* dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius *r*.

Function Description Example(s)	
	Lower-left coordinates are decreased by *r* and upper-right coordinates are increased by *r*. If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when *r* < 0) than both coordinates are set to their average. If *n* is greater than the number of defined dimensions and the cube is being enlarged (*r* > 0), then extra dimensions are added to make *n* altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points. `cube_enlarge('(1,2),(3,4)', 0.5, 3)` → `(0.5, 1.5, -0.5),(3.5, 4.5, 0.5)`

F.13.4. Defaults

This union:

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-------------------
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection:

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-------------
(0, 0),(1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, the lower-dimensional one is assumed to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)','(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)','(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
--------------
t
(1 row)
```

F.13.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

F.13.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (*https://dsf.berkeley.edu/jmh/*) for elucidating the gist of the GiST (*http://gist.cs.berkeley.edu/*), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III `<bruno@wolff.to>` in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich `<josh@root.net>` in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.14. daterange_inclusive — upper bound-inclusive daterange

daterange_inclusive is an extension to the built-in daterange range type. By default, daterange excludes the upper bound of the range — [), whereas daterange_inclusive does not — []. Other than the covered range bound, there are no other differences between daterange and daterange_inclusive.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.14.1. Rationale

At times, it is more convenient to output date ranges with inclusive upper bounds. For example, it may apply to employees' absences. If an employee is absent from January 1, 2025, to January 10, 2025, using the daterange range type will prevent the database from outputting this date range in its entirety. In such cases, you would need to manually subtract one day from the output. The daterange_inclusive extension addresses this issue.

F.14.2. Example Usage

```
CREATE EXTENSION daterange_inclusive;
SELECT daterange('[2024-01-01,2024-06-01]');
      daterange
-------------------------
[2024-01-01,2024-06-02)

SELECT daterange_inclusive('[2024-01-01,2024-06-01]');
   daterange_inclusive
-------------------------
[2024-01-01,2024-06-01]
```

F.15. dbcopies_decoding — 1C module for updating database copies

`dbcopies_decoding` is a 1C module for updating database copies. It is implemented as a logical replication plug-in and provided in `postgrespro-ent-16-contrib`. For the module to work properly, `wal_level` must be set to `logical`. For more information about this module contact 1C support.

F.16. dblink — connect to other Postgres Pro databases

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

See also postgres_fdw, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

dblink_connect — opens a persistent connection to a remote database

Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as CREATE SERVER and CREATE USER MAPPING.

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see Section 37.1.1. Alternatively, the name of a foreign server.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Notes

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated and non-GSSAPI-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```
 dblink_connect
----------------
 OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work
 properly
--       Otherwise, you will receive the following error from dblink_connect():
--       ERROR:  password is required
--       DETAIL:  Non-superuser cannot connect if the server does not request a
 password.
--       HINT:  Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
 dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user
 'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
 dblink_connect
----------------
 OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
 a  | b |       c
----+---+---------------
  0 | a | {a0,b0,c0}
  1 | b | {a1,b1,c1}
  2 | c | {a2,b2,c2}
  3 | d | {a3,b3,c3}
  4 | e | {a4,b4,c4}
  5 | f | {a5,b5,c5}
  6 | g | {a6,b6,c6}
  7 | h | {a7,b7,c7}
  8 | i | {a8,b8,c8}
  9 | j | {a9,b9,c9}
 10 | k | {a10,b10,c10}
(11 rows)

\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;
```

dblink_connect_u

dblink_connect_u — opens a persistent connection to a remote database, insecurely

Synopsis

```
dblink_connect_u(text connstr) returns text
dblink_connect_u(text connname, text connstr) returns text
```

Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

dblink_disconnect

dblink_disconnect — closes a persistent connection to a remote database

Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

Arguments

connname

The name of a named connection to be closed.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-------------------
 OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-------------------
 OK
(1 row)
```

dblink

dblink — executes a query in a remote database

Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
    FROM dblink('dbname=mydb options=-csearch_path=',
                'select proname, prosrc from pg_proc')
      AS t1(proname name, prosrc text)
    WHERE proname LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `proname` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')

dblink_exec

dblink_exec — executes a command in a remote database

Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL command that you wish to execute in the remote database, for example `insert into foo values(0, 'a', '{"a0","b0","c0"}')`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either the command's status string or `ERROR`.

Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
   dblink_exec
-----------------
 INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
 dblink_connect
```

```
----------------
 OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
 ''{"a0","b0","c0"}'');');
   dblink_exec
------------------
 INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo'')',false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

 dblink_exec
-------------
 ERROR
(1 row)
```

dblink_open

dblink_open — opens a cursor in a remote database

Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
 text
```

Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-------------
 OK
(1 row)
```

dblink_fetch

dblink_fetch — returns rows from an open cursor in a remote database

Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
 returns setof record
```

Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
 ''bytea%''');
 dblink_open
-------------
 OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname |  source
----------+----------
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname  |  source
-----------+-----------
 byteain   | byteain
 byteale   | byteale
 bytealike | bytealike
 bytealt   | bytealt
 byteane   | byteane
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname  |   source
------------+------------
 byteanlike | byteanlike
 byteaout   | byteaout
(2 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
----------+--------
(0 rows)
```

dblink_close

dblink_close — closes a cursor in a remote database

Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to close.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-------------
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
--------------
 OK
(1 row)
```

dblink_get_connections

dblink_get_connections — returns the names of all open named dblink connections

Synopsis

```
dblink_get_connections() returns text[]
```

Description

`dblink_get_connections` returns an array of the names of all open named `dblink` connections.

Return Value

Returns a text array of connection names, or NULL if none.

Examples

```
SELECT dblink_get_connections();
```

dblink_error_message

dblink_error_message — gets last error message on the named connection

Synopsis

```
dblink_error_message(text connname) returns text
```

Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

Arguments

connname

Name of the connection to use.

Return Value

Returns last error message, or `OK` if there has been no error in this connection.

Notes

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

Examples

```
SELECT dblink_error_message('dtest1');
```

dblink_send_query

dblink_send_query — sends an async query to a remote database

Synopsis

```
dblink_send_query(text connname, text sql) returns int
```

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

connname

Name of the connection to use.

sql

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

dblink_is_busy

dblink_is_busy — checks if connection is busy with an async query

Synopsis

```
dblink_is_busy(text connname) returns int
```

Description

`dblink_is_busy` tests whether an async query is in progress.

Arguments

connname

Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

Examples

```
SELECT dblink_is_busy('dtest1');
```

dblink_get_notify

dblink_get_notify — retrieve async notifications on a connection

Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
 text)
```

Description

`dblink_get_notify` retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, `LISTEN` must first be issued, using `dblink_exec`. For details see LISTEN and NOTIFY.

Arguments

connname

The name of a named connection to get notifications on.

Return Value

Returns `setof (notify_name text, be_pid int, extra text)`, or an empty set if none.

Examples

```
SELECT dblink_exec('LISTEN virtual');
 dblink_exec
-------------
 LISTEN
(1 row)

SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-------------+--------+-------
(0 rows)

NOTIFY virtual;
NOTIFY

SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-------------+--------+-------
 virtual     |   1229 |
(1 row)
```

dblink_get_result

dblink_get_result — gets an async query result

Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

Arguments

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, dblink fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
 dblink_connect
----------------
 OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
 t1;
 t1
----
  1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 |     f3
----+----+------------
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 | f3
----+----+----
(0 rows)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
 select * from foo where f1 > 6') AS t1;
 t1
----
  1
(1 row)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 |     f3
----+----+------------
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 |      f3
----+----+---------------
  7 | h  | {a7,b7,c7}
  8 | i  | {a8,b8,c8}
  9 | j  | {a9,b9,c9}
 10 | k  | {a10,b10,c10}
(4 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 | f3
----+----+----
(0 rows)
```

dblink_cancel_query

dblink_cancel_query — cancels any active query on the named connection

Synopsis

```
dblink_cancel_query(text connname) returns text
```

Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

Arguments

connname

Name of the connection to use.

Return Value

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

Examples

```
SELECT dblink_cancel_query('dtest1');
```

dblink_get_pkey

dblink_get_pkey — returns the positions and field names of a relation's primary key fields

Synopsis

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *`N`*; it is the number of the field within the primary key, not the number within the table's columns.

Examples

```
CREATE TABLE foobar (
    f1 int,
    f2 int,
    f3 int,
    PRIMARY KEY (f1, f2, f3)
);
CREATE TABLE

SELECT * FROM dblink_get_pkey('foobar');
 position | colname
----------+---------
        1 | f1
        2 | f2
        3 | f3
(3 rows)
```

dblink_build_sql_insert

dblink_build_sql_insert — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_insert(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');
             dblink_build_sql_insert
------------------------------------------------
```

```
 INSERT INTO foo(f1,f2,f3) VALUES('1','b''a','1')
(1 row)
```

dblink_build_sql_delete

dblink_build_sql_delete — builds a DELETE statement using supplied values for primary key field values

Synopsis

```
dblink_build_sql_delete(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds an SQL `DELETE` command that will delete the row with the given primary key values.

Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

`primary_key_attnums`

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

`num_primary_key_atts`

The number of primary key fields.

`tgt_pk_att_vals_array`

Values of the primary key fields to be used in the resulting `DELETE` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *`primary_key_attnums`* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');
           dblink_build_sql_delete
---------------------------------------------
 DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
```

dblink_build_sql_update

dblink_build_sql_update — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_update(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `UPDATE` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The `UPDATE` command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `UPDATE` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
```

```
                    dblink_build_sql_update
-----------------------------------------------------------
 UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

F.17. dbms_lob — operate on large objects

dbms_lob is a Postgres Pro extension that allows operating on LOBs: `BLOB`, `CLOB`, `BFILE`, and temporary LOBs. The extension can be used to access and manipulate specific parts of a LOB or complete LOBs. The functionality provided by this module overlaps substantially with the functionality of Oracle's `DBMS_LOB` package.

> **Note**
>
> Note that the dbms_lob extension depends on both pgpro_bfile and pgpro_sfile. You must install these extensions before creating dbms_lob, or you can install all dependencies automatically with:
>
> ```
> CREATE EXTENSION dbms_lob CASCADE;
> ```

F.17.1. Installation

The `dbms_lob` extension is a built-in extension included into Postgres Pro Enterprise. To enable `dbms_lob`, create the extension using the following query:

```
CREATE EXTENSION dbms_lob;
```

F.17.2. Data Types

The dbms_lob extension works with several data types:

- The `bfile` type is provided by pgpro_bfile.

  ```
  CREATE TYPE BFILE AS (
      dir_id int,
      file_name text
  );
  ```

  Table F.9. `bfile` Parameters

Parameter	Description
`dir_id`	The ID of the directory where the `bfile` is stored.
`file_name`	The name of the file to read the `bfile` from.

- The `blob` type stores binary data and has the same interface as Oracle's `BLOB`. It is provided by pgpro_sfile.

  ```
  CREATE TYPE dbms_lob.blob AS (
      temp_data   bytea,
      mime        text,
      sf          @extschema:pgpro_sfile@.sfile
  );
  ```

  Table F.10. `blob` Parameters

Parameter	Description
`sf`	`sfile` object on disk, which contains BLOB.
`temp_data`	Temporary BLOB data stored in memory.
`mime`	Auxiliary data defining the type of data stored in BLOB.

- The `clob` type is the equivalent of Oracle's `CLOB` and `NCLOB`. Only the UTF-8 encoding is supported.

  ```
  CREATE TYPE CLOB AS (
      t       text,
  ```

```
    istemp  bool,
    mime    text
);
```

Table F.11. `clob` Parameters

Parameter	Description
`t`	`text` object on disk, which stores data.
`istemp`	Defines if the object is temporary.
`mime`	Auxiliary data defining the type of data stored in CLOB.

F.17.3. Utility Functions

`bfilename(`*`dirname`* `text, `*`filename`* `text) returns bfile`

Creates a `bfile` object associated with a physical file in the file system. Here *`dirname`* is the name of the directory object created with `bfile_directory_create()` where the file *`filename`* is located.

`empty_blob() returns blob`

Creates an empty `blob` object, which contains an `sfile` without data. It can be populated with data using write functions.

`empty_clob() returns clob`

Creates an empty `clob` object, which contains an empty string. It can be populated with data using write functions.

`to_blob(`*`b`* `bytea) returns blob`
`to_blob(`*`f`* `bfile, `*`mime_type`* `text) returns blob`

Converts a `bytea` object to a `blob`. If the original file is `bfile`, the `mime` data type can be specified.

`to_clob(`*`t`* `text) returns clob`
`to_clob(`*`t`* `varchar) returns clob`
`to_clob(`*`b`* `bfile, `*`int`* `csid, `*`mime`* `text) returns clob`

Converts text objects to `clob` objects. If the original file is `bfile`, its data is read and converted into `clob`. Only the UTF-8 encoding is supported.

`to_raw(`*`b`* `blob) returns clob`
`to_raw(`*`b`* `bfile) returns clob`

Copies the data from a `blob` or `bfile` file into a `bytea`. Only the first GB of data is processed.

F.17.4. dbms_lob Functions and Procedures

F.17.4.1. Opening and Closing LOBs

`open(`*`file_loc`* `IN OUT bfile, `*`open_mode`* `IN int)`
`open(`*`lob_loc`* `IN OUT blob, `*`open_mode`* `IN int)`
`open(`*`lob_loc`* `IN OUT clob, `*`open_mode`* `IN int)`

`open(bfile)` opens a `bfile` object. The *`open_mode`* parameter specifies if the file is to be open in read/write or read-only mode. For `bfile`, only read-only mode is supported (0). The functions `open(blob)` and `open(clob)` do nothing and exist only for syntax compatibility.

`isopen(`*`file_loc`* `IN bfile)`
`isopen(`*`lob_loc`* `IN blob)`
`isopen(`*`lob_loc`* `IN clob)`

`isopen(bfile)` checks if a `bfile` object is open. Returns 1 if the LOB is open, otherwise 0. The functions `isopen(blob)` and `isopen(clob)` always return 1 and exist only for syntax compatibility.

```
close(file_loc IN OUT bfile)
close(lob_loc IN OUT blob)
close(lob_loc IN OUT clob)
```

close(bfile) checks if a bfile object is open, and if it is, closes it. The functions close(blob) and close(clob) do nothing and exist only for syntax compatibility.

```
createtemporary(lob_loc IN OUT blob, cache IN bool, dur IN int default 10)
createtemporary(lob_loc IN OUT clob, cache IN bool, dur IN int default 10)
```

Creates a temporary LOB, with blob data stored as bytea and clob data stored as text.

```
freetemporary(lob_loc IN OUT blob)
freetemporary(lob_loc IN OUT clob)
```

Releases resources associated with the temporary LOB.

F.17.4.2. Reading LOBs

```
getlength(file_loc IN bfile)
getlength(lob_loc IN blob)
getlength(lob_loc IN clob)
```

Returns the length of a blob or bfile in bytes or a clob in characters.

```
read(file_loc IN bfile, amount IN OUT int, offset IN int, buffer OUT bytea)
read(lob_loc IN blob, amount IN OUT int, offset IN int, buffer OUT bytea)
read(lob_loc IN clob, amount IN OUT int, offset IN int, buffer OUT text)
```

Reads a piece of a LOB, and writes the specified amount of bytes (blob/bfile) or characters (clob) into the *buffer* parameter, starting from an absolute *offset* from the beginning of the LOB. Note that *offset* 1 should be specified to read from the beginning.

```
get_storage_limit(lob_loc IN blob)
get_storage_limit(lob_loc IN clob)
```

Returns the LOB storage limit for the specified LOB.

```
substr(file_loc IN bfile, amount IN int, offset IN int)
substr(lob_loc IN blob, amount IN int, offset IN int)
substr(lob_loc IN clob, amount IN int, offset IN int)
```

Returns *amount* of bytes (blob/bfile) or characters (clob) of a LOB, starting from an absolute *offset* from the beginning of the LOB.

```
instr(file_loc IN bfile, pattern IN int, offset IN bigint default 1, nth IN bigint
default 1)
instr(lob_loc IN blob, pattern IN int, offset IN bigint default 1, nth IN bigint default 1)
instr(lob_loc IN clob, pattern IN int, offset IN bigint default 1, nth IN bigint default 1)
```

Returns the matching position of the *nth* occurrence of the *pattern* in the LOB, starting from the specified *offset*. Returns 0 if the *pattern* is not found. Only the first GB of data is searched.

F.17.4.3. Updating LOBs

```
write(lob_loc IN OUT blob, amount IN int, offset IN bigint, buffer IN bytea)
write(lob_loc IN OUT clob, amount IN int, offset IN int, buffer IN text)
```

Writes a specified *amount* of data into the internal LOB, starting from the absolute *offset* from the beginning of the LOB. The data is taken from the *buffer*. If the specified *offset* exceeds the current size of the LOB, the value is padded with zero bytes (for blob) or spaces (for clob).

If *buffer* is longer than *amount*, only the specified number of bytes (for `blob`) or characters (for `clob`) is written. This ensures that exactly *amount* of data is written into the internal LOB.

```
writeappend(lob_loc IN OUT blob, amount IN int, buffer IN bytea)
writeappend(lob_loc IN OUT clob, amount IN int, buffer IN text)
```

Writes a specified *amount* of data to the end of an internal LOB. The data is written from the *buffer* parameter.

```
erase(lob_loc IN OUT blob, amount IN OUT int, offset IN bigint default 1)
erase(lob_loc IN OUT clob, amount IN OUT int, offset IN int default 1)
```

Erases an entire internal LOB or part of an internal LOB. When data is erased from the middle of a LOB, zero-byte fillers (temporary `blob`) or spaces (`clob`) are written. Non-temporary `blob` objects can only be deleted as a whole.

```
trim(lob_loc IN OUT blob, newlen IN bigint)
trim(lob_loc IN OUT clob, newlen IN int)
```

Trims the value of the internal LOB to the length you specify in the *newlen* parameter. Specify the length in bytes for temporary `blob`, and specify the length in characters for `clob`. For non-temporary `blob`, works only if the new length is 0, which means erasing the object.

F.17.4.4. Operations with Multiple LOBs

```
compare(lob_1 IN bfile, lob_2 IN bfile, amount IN bigint, offset_1 IN bigint default 1,
offset_2 IN bigint default 1) returns int
compare(lob_1 IN blob, lob_2 IN blob, amount IN int default 1024*1024*1024-8, offset_1
IN bigint default 1, offset_2 IN bigint default 1) returns int
compare(lob_1 IN clob, lob_2 IN clob, amount IN int default (1024*1024*1024-8)/2, offset_1
IN int default 1, offset_2 IN int default 1) returns int
```

Compares two entire LOBs or parts of two LOBs. You can only compare LOBs of the same datatype. For `bfile` and `blob`, binary comparison is performed. For `clob`, files are compared according to the current database collation.

```
append(lob_1 IN OUT blob, lob_2 IN blob)
append(lob_1 IN OUT clob, lob_2 IN clob)
```

Appends the contents of a source internal LOB to a destination LOB. It appends the complete source LOB.

```
copy(dest_lob IN OUT blob, src_lob IN blob, amount IN bigint, dest_offset IN bigint
default 1, src_offset IN bigint default 1) returns int
copy(dest_lob IN OUT clob, src_lob IN clob, amount IN int, dest_offset IN int default
1, src_offset IN int default 1) returns int
```

Copies all, or a part of, a source internal LOB to a destination internal LOB. You can specify the offsets for both the source and destination LOBs, and the number of bytes or characters to copy.

```
converttoblob(dest_lob IN OUT blob, src_clob IN clob, amount IN int, dest_offset IN OUT
bigint, src_offset IN OUT int, blob_csid IN int, lang_context IN OUT int, warning OUT int)
```

Reads character data from a source `clob`, converts the character data to the specified character set, writes the converted data to a destination `blob` in binary format, and returns the new offsets. Only the UTF-8 encoding is supported.

```
converttoclob(dest_lob IN OUT clob, src_blob IN blob, amount IN int, dest_offset IN OUT
int, src_offset IN OUT bigint, blob_csid IN int, lang_context IN OUT int, warning OUT int)
```

Reads binary data from a source `blob`, converts it into UTF-8 encoding, and writes the converted character data to a destination `clob`.

F.17.4.5. Legacy API

`fileexists(file_loc IN bfile) returns int`

Finds out if a specified `bfile` locator points to a file that actually exists on the server file system. Implemented as `bfile_fileexists`.

`fileopen(file_loc IN OUT bfile, open_mode IN int) returns int`

Opens the specified `bfile` for read-only access. Implemented as `bfile_open`.

`fileisopen(file_loc IN bfile) returns int`

Finds out whether the specified `bfile` was opened.

`loadfromfile(dest_lob IN OUT blob, src_bfile IN bfile, amount IN int default 1024*1024*1024-8, dest_offset IN bigint default 1, src_offset IN bigint default 1)`

Converts data from the specified `bfile` to `blob`.

`fileclose(file_loc IN OUT bfile)`

Closes the previously opened `bfile`. Implemented as `bfile_close`.

`filecloseall()`

Closes all `bfile` files opened in the session. Implemented as `bfile_close_all`.

`filegetname(file_loc IN bfile, dir_alias OUT text, filename OUT text)`

Determines the directory object and filename. This function only indicates the directory object name and filename assigned to the locator, not if the physical file or directory actually exists. Implemented as `bfile_directory_get_alias_by_id`.

F.17.4.6. Other Operations

`loadblobfromfile(dest_lob IN OUT blob, src_bfile IN bfile, amount IN int default 1024*1024*1024-8, dest_offset IN bigint default 1, src_offset IN bigint default 1) returns int`

Synonym for `loadfromfile()`.

`loadclobfromfile(dest_lob IN OUT clob, src_bfile IN bfile, amount IN int, dest_offset IN OUT int, src_offset IN OUT bigint, bfile_csid IN int, lang_context IN OUTint, warning OUTint)`

Loads data from a `bfile` to an internal `clob`.

```
setcontenttype(lob_loc IN OUT blob, contenttype IN text)
setcontenttype(lob_loc IN OUT clob, contenttype IN text)
```

Sets the content type string associated with the LOB.

```
getcontenttype(lob_loc IN blob) returns text
getcontenttype(lob_loc IN clob) returns text
```

Returns the content type string associated with the LOB.

```
getchunksize(lob_loc IN blob) returns text
getchunksize(lob_loc IN clob) returns text
```

Returns the amount of space used in the LOB chunk to store the LOB value.

F.17.5. Example

Below is the example of how the dbms_lob extension works.

```
DO
```

```
$$
DECLARE
  cur_clob  dbms_lob.clob;
  buffer    text;
  amount    int := 3000;
BEGIN
  cur_clob := dbms_lob.empty_clob();
  cur_clob.t := 'just some sample text';
  raise notice 'clob length: %', dbms_lob.getlength(cur_clob);
  call dbms_lob.read(cur_clob, amount, 1, buffer);
  raise notice 'all clob read: %', buffer;
  amount := 6;
  call dbms_lob.read(cur_clob, amount, 4, buffer);
  raise notice 'clob read from 4 position for 6 symbols: %', buffer;
  raise notice 'storage limit: %', dbms_lob.get_storage_limit(cur_clob);
  raise notice 'clob substr from 6 position for 8 symbols: %',
 dbms_lob.substr(cur_clob, 8, 6);
  raise notice 'third postion of letter s in clob: %', dbms_lob.instr(cur_clob, 's', 1,
 3);

  call dbms_lob.write(cur_clob, 6, 4, 'foobar');
  raise notice 'new clob contents: %', cur_clob.t;
  call dbms_lob.write(cur_clob, 3, 25, 'baz');
  raise notice 'new clob contents: %', cur_clob.t;

  call dbms_lob.writeappend(cur_clob, 4, 'test');
  raise notice 'new clob contents: %', cur_clob.t;

  amount := 3;
  call dbms_lob.erase(cur_clob, amount, 2);
  raise notice 'amount of symbols deleted: %', amount;
  raise notice 'new clob contents: %', cur_clob.t;
  call dbms_lob.erase(cur_clob, amount, 30);
  raise notice 'amount of symbols deleted: %', amount;
  raise notice 'new clob contents: %', cur_clob.t;

  call dbms_lob.trim_(cur_clob, 22);
  raise notice 'new clob contents: %', cur_clob.t;
END;
$$;
--output
NOTICE:  clob length: 21
NOTICE:  all clob read: just some sample text
NOTICE:  clob read from 4 position for 6 symbols: t some
NOTICE:  storage limit: 536870908
NOTICE:  clob substr from 6 position for 8 symbols: some sam
NOTICE:  third postion of letter s in clob: 11
NOTICE:  new clob contents: jusfoobar sample text
NOTICE:  new clob contents: jusfoobar sample text   baz
NOTICE:  new clob contents: jusfoobar sample text   baztest
NOTICE:  amount of symbols deleted: 3
NOTICE:  new clob contents: j   oobar sample text   baztest
NOTICE:  amount of symbols deleted: 2
NOTICE:  new clob contents: j   oobar sample text   bazte
NOTICE:  new clob contents: j   oobar sample text
```

And here is how working with LOBs located in a database may look like:

```
-- Create a table and add data
```

```
CREATE TABLE dbms_lob_test (id INTEGER GENERATED ALWAYS AS IDENTITY, blob_col
 DBMS_LOB.BLOB);
INSERT INTO dbms_lob_test (blob_col) VALUES
 (dbms_lob.to_blob(decode('d6b7a686ab4d4e9c5d2cbf49db6bc0f1', 'hex')));

DO $$
DECLARE
  v_lob_loc DBMS_LOB.BLOB;
  v_buffer BYTEA;
  v_amount INTEGER := 32700;
  v_offset BIGINT := 1;
  v_length BIGINT;
BEGIN
  SELECT (blob_col).* INTO v_lob_loc FROM dbms_lob_test WHERE id=1;
  CALL dbms_lob.open(v_lob_loc, 0); -- Optional for DBMS_LOB.BLOB
  SELECT DBMS_LOB.getlength(v_lob_loc) into v_length;
  RAISE NOTICE 'BLOB len=%', v_length;
  CALL dbms_lob.read(v_lob_loc, v_amount, v_offset, v_buffer);
  RAISE NOTICE 'Read % bytes', v_amount;
  RAISE NOTICE 'Buffer: %', encode(v_buffer, 'hex');
  CALL dbms_lob.close(v_lob_loc); -- Optional for DBMS_LOB.BLOB
END $$;
```

The output will look as follows:

```
BLOB len=16
Read 16 bytes
Buffer: d6b7a686ab4d4e9c5d2cbf49db6bc0f1
```

F.18. dict_int — example full-text search dictionary for integers

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.18.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “`+`” or “`-`” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

F.18.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
 ts_lexize
-----------
 {123456}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```

F.19. dict_xsyn — example synonym full-text search dictionary

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.19.1. Configuration

A dict_xsyn dictionary accepts the following options:

- matchorig controls whether the original word is accepted by the dictionary. Default is true.
- matchsynonyms controls whether the synonyms are accepted by the dictionary. Default is false.
- keeporig controls whether the original word is included in the dictionary's output. Default is true.
- keepsynonyms controls whether the synonyms are included in the dictionary's output. Default is true.
- rules is the base name of the file containing the list of synonyms. This file must be stored in $SHAREDIR/tsearch_data/ (where $SHAREDIR means the Postgres Pro installation's shared-data directory). Its name must end in .rules (which is not to be included in the rules parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

  ```
  word syn1 syn2 syn3
  ```

- The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at xsyn_sample.rules, which is installed in $SHAREDIR/tsearch_data/, for an example.

F.19.2. Usage

Installing the dict_xsyn extension creates a text search template xsyn_template and a dictionary xsyn based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
      ts_lexize
-----------------------
 {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'word');
      ts_lexize
-----------------------
 {word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
 MATCHSYNONYMS=true);
```

```
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
      ts_lexize
-----------------------
 {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
 MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
      ts_lexize
-----------------------
 {word}
```

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.20. dump_stat — functions to backup and recover the pg_statistic table

The dump_stat module provides functions that allow you to backup and recover the contents of the pg_statistic table. When performing a dump/restore, you can use dump_stat to migrate the original statistics to the new server instead of running the ANALYZE command for the whole database cluster, which can significantly reduce downtime for large databases. The dump_statistic function generates INSERT statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided dump_stat functions.

Note that the definition of the pg_statistic table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.20.1. Installation

The dump_stat extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the CREATE EXTENSION command to enable dump_stat, as follows:

```
CREATE EXTENSION dump_stat;
```

F.20.2. Functions

```
anyarray_to_text(array anyarray) returns text
```

Returns the given array as text.

```
dump_statistic() returns setof text
```

dump_statistic dumps the contents of the pg_statistic system catalog. It produces an INSERT statement per each tuple of the pg_statistic, excluding the ones that contain statistical data for tables in the information_schema and pg_catalog schemas.

The INSERT statement takes form of

```
WITH upsert as (
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]
  WHERE starelid = t_relname::regclass
    AND to_attname(t_relname, staattnum) = t_attname
    AND to_atttype(t_relname, staattnum) = t_atttype
    AND stainherit = t_stainherit
  RETURNING *)
ins as (
  SELECT expression [, ...]
  WHERE NOT EXISTS (SELECT * FROM upsert)
    AND to_attnum(t_relname, t_attname) IS NOT NULL
    AND to_atttype(t_relname, t_attname) = t_atttype)
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;

where expression can be one of:

array_in(array_text, type_name::regtype::oid, -1)
value::type_name
```

To save the produced statements, redirect the psql output into a file using standard psql options. For details on the available psql options, see psql. Meta-commands starting with a backslash are not supported.

For example, to save statistics for the *dbname* database into a dump_stat.sql file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text) returns setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text) returns setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass) returns setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that contains statistical data for the specified `relation`.

`to_schema_qualified_operator(opid oid) returns text`

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)'::regoperator);
          to_schema_qualified_operator
-----------------------------------------------
 pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid) returns text`

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid) returns text`

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray) returns oid`

Returns the element type of the given array as `oid`. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
 anyarray_elemtype
-------------------
                23
(1 row)
```

`to_attname(relation regclass, colnum int2) returns text`

Given a relation name `relation` and a column number `colnum`, returns the column name as `text`.

`to_attnum(relation regclass, col text) returns int2`

Given a relation name `relation` and a column name `col`, returns the column number as `int2`.

`to_atttype(relation regclass, col text) returns text`

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as `text`.

`to_atttype(relation regclass, colnum int2) returns text`

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as `text`.

`to_namespace(nsp text) returns oid`

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the `oid` of the given schema.

`get_namespace(relation oid) returns oid`

`get_namespace` returns the schema of the given relation as `oid`.

F.21. earthdistance — calculate great-circle distances

The earthdistance module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the cube module. The second one is based on the built-in point data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the *PostGIS* project.)

The cube module must be installed before earthdistance can be installed (although you can use the CASCADE option of CREATE EXTENSION to install both in one command).

> **Caution**
>
> It is strongly recommended that earthdistance and cube be installed in the same schema, and that that schema be one for which CREATE privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if earthdistance's schema contains objects defined by a hostile user. Furthermore, when using earthdistance's functions after installation, the entire search path should contain only trusted schemas.

F.21.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A *domain* earth over type cube is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the earth() function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change earth() to return a radius of 180/pi() so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F.12.

Table F.12. Cube-Based Earthdistance Functions

Function Description
earth () → float8 Returns the assumed radius of the Earth.
sec_to_gc (float8) → float8 Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
gc_to_sec (float8) → float8 Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
ll_to_earth (float8, float8) → earth Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.

Function Description
`latitude` (`earth`) → `float8` Returns the latitude in degrees of a point on the surface of the Earth.
`longitude` (`earth`) → `float8` Returns the longitude in degrees of a point on the surface of the Earth.
`earth_distance` (`earth`, `earth`) → `float8` Returns the great circle distance between two points on the surface of the Earth.
`earth_box` (`earth`, `float8`) → `cube` Returns a box suitable for an indexed search using the `cube @>` operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using `earth_distance` should be included in the query.

F.21.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F.13.

Table F.13. Point-Based Earthdistance Operators

Operator Description
`point <@> point` → `float8` Computes the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

F.22. fasttrun — a transaction unsafe function to truncate temporary tables

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing pg_class size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

F.22.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

F.22.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
    loop
      PERFORM fasttruncate('tt1');
    end loop;
  end;
$$ language plpgsql;
```

F.22.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.23. file_fdw — access data files in the server's file system

The file_fdw module provides the foreign-data wrapper file_fdw, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by COPY FROM; see COPY for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

filename

Specifies the file to be read. Relative paths are relative to the data directory. Either filename or program must be specified, but not both.

program

Specifies the command to be executed. The standard output of this command will be read as though COPY FROM PROGRAM were used. Either program or filename must be specified, but not both.

format

Specifies the data format, the same as COPY's FORMAT option.

header

Specifies whether the data has a header line, the same as COPY's HEADER option.

delimiter

Specifies the data delimiter character, the same as COPY's DELIMITER option.

quote

Specifies the data quote character, the same as COPY's QUOTE option.

escape

Specifies the data escape character, the same as COPY's ESCAPE option.

null

Specifies the data null string, the same as COPY's NULL option.

encoding

Specifies the data encoding, the same as COPY's ENCODING option.

Note that while COPY allows options such as HEADER to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate COPY options typically written without a value, you can pass the value TRUE, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

force_not_null

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level null option). This has the same effect as listing the column in COPY's FORCE_NOT_NULL option.

force_null

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the

null string are returned as NULL. This has the same effect as listing the column in COPY's FORCE_NULL option.

COPY's FORCE_QUOTE option is currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role pg_read_server_files (to use a filename) or the role pg_execute_server_program (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the program option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using file_fdw, EXPLAIN shows the name of the file to be read or program to be run. For a file, unless COSTS OFF is specified, the file size (in bytes) is shown as well.

Example F.5. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for file_fdw is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call pglog.csv. First, install file_fdw as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the CREATE FOREIGN TABLE command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (
  log_time timestamp(3) with time zone,
  user_name text,
  database_name text,
  process_id integer,
  connection_from text,
  session_id text,
  session_line_num bigint,
  command_tag text,
  session_start_time timestamp with time zone,
  virtual_transaction_id text,
  transaction_id bigint,
  error_severity text,
  sql_state_code text,
  message text,
  detail text,
  hint text,
  internal_query text,
  internal_query_pos integer,
  context text,
  query text,
  query_pos integer,
  location text,
  application_name text,
```

```
  backend_type text,
  leader_pid integer,
  query_id bigint
) SERVER pglog
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

F.24. fulleq — an additional equivalence operator for compatibility with Microsoft SQL Server

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

F.24.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

F.24.2. Operator fulleq

The == operator is defined for the following data types:

- bool
- bytea
- char
- name
- int2
- int4
- int8
- int2vector
- text
- oid
- xid
- cid
- oidvector
- float4
- float8
- abstime
- reltime
- macaddr
- inet
- cidr
- varchar
- date
- time
- timestamp
- timestamptz
- interval
- timetz

F.24.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.25. fuzzystrmatch — determine string similarities and distance

The fuzzystrmatch module provides several functions to determine similarities and distance between strings.

> **Caution**
>
> At present, the soundex, metaphone, dmetaphone, and dmetaphone_alt functions do not work well with multibyte encodings (such as UTF-8). Use daitch_mokotoff or levenshtein with such data.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.25.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The fuzzystrmatch module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The soundex function converts a string to its Soundex code. The difference function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — similarity would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');

SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.25.2. Daitch-Mokotoff Soundex

Like the original Soundex system, Daitch-Mokotoff Soundex matches similar-sounding names by converting them to the same code. However, Daitch-Mokotoff Soundex is significantly more useful for non-English names than the original system. Major improvements over the original system include:

- The code is based on the first six meaningful letters rather than four.
- A letter or combination of letters maps into ten possible codes rather than seven.
- Where two consecutive letters have a single sound, they are coded as a single number.

- When a letter or combination of letters may have different sounds, multiple codes are emitted to cover all possibilities.

This function generates the Daitch-Mokotoff soundex codes for its input:

```
daitch_mokotoff(source text) returns text[]
```

The result may contain one or more codes depending on how many plausible pronunciations there are, so it is represented as an array.

Since a Daitch-Mokotoff soundex code consists of only 6 digits, *source* should be preferably a single word or name.

Here are some examples:

```
SELECT daitch_mokotoff('George');
 daitch_mokotoff
-----------------
 {595000}

SELECT daitch_mokotoff('John');
 daitch_mokotoff
-----------------
 {160000,460000}

SELECT daitch_mokotoff('Bierschbach');
                      daitch_mokotoff
------------------------------------------------------------
 {794575,794574,794750,794740,745750,745740,747500,747400}

SELECT daitch_mokotoff('Schwartzenegger');
 daitch_mokotoff
-----------------
 {479465}
```

For matching of single names, returned text arrays can be matched directly using the `&&` operator: any overlap can be considered a match. A GIN index may be used for efficiency, see Chapter 71 and this example:

```
CREATE TABLE s (nm text);
CREATE INDEX ix_s_dm ON s USING gin (daitch_mokotoff(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
  ('Schwartzenegger'),
  ('John'),
  ('James'),
  ('Steinman'),
  ('Steinmetz');

SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Swartzenegger');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jane');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jens');
```

For indexing and matching of any number of names in any order, Full Text Search features can be used. See Chapter 12 and this example:

```
CREATE FUNCTION soundex_tsvector(v_name text) RETURNS tsvector
BEGIN ATOMIC
  SELECT to_tsvector('simple',
                     string_agg(array_to_string(daitch_mokotoff(n), ' '), ' '))
```

```
  FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE FUNCTION soundex_tsquery(v_name text) RETURNS tsquery
BEGIN ATOMIC
  SELECT string_agg('(' || array_to_string(daitch_mokotoff(n), '|') || ')',
 '&')::tsquery
  FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE TABLE s (nm text);
CREATE INDEX ix_s_txt ON s USING gin (soundex_tsvector(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
  ('John Doe'),
  ('Jane Roe'),
  ('Public John Q.'),
  ('George Best'),
  ('John Yamson');

SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('jane doe');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john public');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('besst, giorgio');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('Jameson John');
```

If it is desired to avoid recalculation of soundex codes during index rechecks, an index on a separate column can be used instead of an index on an expression. A stored generated column can be used for this; see Section 5.3.

F.25.3. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(source text, target text, ins_cost int, del_cost int, sub_cost int) returns
 int
levenshtein(source text, target text) returns int
levenshtein_less_equal(source text, target text, ins_cost int, del_cost int, sub_cost
 int, max_d int) returns int
levenshtein_less_equal(source text, target text, max_d int) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-------------
           2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
```

```
 levenshtein
-------------
           3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
 levenshtein_less_equal
------------------------
                      3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
 levenshtein_less_equal
------------------------
                      4
(1 row)
```

F.25.4. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(source text, max_output_length int) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----------
 KM
(1 row)
```

F.25.5. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(source text) returns text
dmetaphone_alt(source text) returns text
```

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
------------
 KMP
(1 row)
```

F.26. hstore — hstore key/value datatype

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.26.1. `hstore` External Representation

The text representation of an `hstore`, used for input and output, includes zero or more *`key`* `=>` *`value`* pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
  hstore
----------
 "a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “NULL”.

> **Note**
>
> Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.26.2. `hstore` Operators and Functions

The operators provided by the `hstore` module are shown in Table F.14, the functions in Table F.15.

Table F.14. `hstore` Operators

Operator **Description** **Example(s)**
`hstore -> text → text` Returns value associated with given key, or `NULL` if not present. `'a=>x, b=>y'::hstore -> 'a' → x`
`hstore -> text[] → text[]` Returns values associated with given keys, or `NULL` if not present.

Operator **Description** **Example(s)**
`'a=>x, b=>y, c=>z'::hstore -> ARRAY['c','a']` → `{"z","x"}`
`hstore || hstore` → `hstore` Concatenates two `hstore`s. `'a=>b, c=>d'::hstore || 'c=>x, d=>q'::hstore` → `"a"=>"b", "c"=>"x", "d"=>"q"`
`hstore ? text` → `boolean` Does `hstore` contain key? `'a=>1'::hstore ? 'a'` → `t`
`hstore ?& text[]` → `boolean` Does `hstore` contain all the specified keys? `'a=>1,b=>2'::hstore ?& ARRAY['a','b']` → `t`
`hstore ?| text[]` → `boolean` Does `hstore` contain any of the specified keys? `'a=>1,b=>2'::hstore ?| ARRAY['b','c']` → `t`
`hstore @> hstore` → `boolean` Does left operand contain right? `'a=>b, b=>1, c=>NULL'::hstore @> 'b=>1'` → `t`
`hstore <@ hstore` → `boolean` Is left operand contained in right? `'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL'` → `f`
`hstore - text` → `hstore` Deletes key from left operand. `'a=>1, b=>2, c=>3'::hstore - 'b'::text` → `"a"=>"1", "c"=>"3"`
`hstore - text[]` → `hstore` Deletes keys from left operand. `'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b']` → `"c"=>"3"`
`hstore - hstore` → `hstore` Deletes pairs from left operand that match pairs in the right operand. `'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore` → `"a"=>"1", "c"=>"3"`
`anyelement #= hstore` → `anyelement` Replaces fields in the left operand (which must be a composite type) with matching values from `hstore`. `ROW(1,3) #= 'f1=>11'::hstore` → `(11,3)`
`%% hstore` → `text[]` Converts `hstore` to an array of alternating keys and values. `%% 'a=>foo, b=>bar'::hstore` → `{a,foo,b,bar}`
`%# hstore` → `text[]` Converts `hstore` to a two-dimensional key/value array. `%# 'a=>foo, b=>bar'::hstore` → `{{a,foo},{b,bar}}`

Table F.15. `hstore` Functions

Function Description Example(s)
`hstore ( record ) → hstore` Constructs an `hstore` from a record or row. `hstore(ROW(1,2))` → `"f1"=>"1", "f2"=>"2"`
`hstore ( text[] ) → hstore` Constructs an `hstore` from an array, which may be either a key/value array, or a two-dimensional array. `hstore(ARRAY['a','1','b','2'])` → `"a"=>"1", "b"=>"2"` `hstore(ARRAY[['c','3'],['d','4']])` → `"c"=>"3", "d"=>"4"`
`hstore ( text[], text[] ) → hstore` Constructs an `hstore` from separate key and value arrays. `hstore(ARRAY['a','b'], ARRAY['1','2'])` → `"a"=>"1", "b"=>"2"`
`hstore ( text, text ) → hstore` Makes a single-item `hstore`. `hstore('a', 'b')` → `"a"=>"b"`
`akeys ( hstore ) → text[]` Extracts an `hstore`'s keys as an array. `akeys('a=>1,b=>2')` → `{a,b}`
`skeys ( hstore ) → setof text` Extracts an `hstore`'s keys as a set. `skeys('a=>1,b=>2')` → `a` `b`
`avals ( hstore ) → text[]` Extracts an `hstore`'s values as an array. `avals('a=>1,b=>2')` → `{1,2}`
`svals ( hstore ) → setof text` Extracts an `hstore`'s values as a set. `svals('a=>1,b=>2')` → `1` `2`
`hstore_to_array ( hstore ) → text[]` Extracts an `hstore`'s keys and values as an array of alternating keys and values. `hstore_to_array('a=>1,b=>2')` → `{a,1,b,2}`
`hstore_to_matrix ( hstore ) → text[]` Extracts an `hstore`'s keys and values as a two-dimensional array. `hstore_to_matrix('a=>1,b=>2')` → `{{a,1},{b,2}}`
`hstore_to_json ( hstore ) → json` Converts an `hstore` to a `json` value, converting all non-null values to JSON strings. This function is used implicitly when an `hstore` value is cast to `json`. `hstore_to_json('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4')` → `{"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}`

Function
Description
Example(s)

`hstore_to_jsonb ( hstore ) → jsonb`
Converts an `hstore` to a `jsonb` value, converting all non-null values to JSON strings.
This function is used implicitly when an `hstore` value is cast to `jsonb`.
`hstore_to_jsonb('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}`

`hstore_to_json_loose ( hstore ) → json`
Converts an `hstore` to a `json` value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.
`hstore_to_json_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}`

`hstore_to_jsonb_loose ( hstore ) → jsonb`
Converts an `hstore` to a `jsonb` value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.
`hstore_to_jsonb_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}`

`slice ( hstore, text[] ) → hstore`
Extracts a subset of an `hstore` containing only the specified keys.
`slice('a=>1,b=>2,c=>3'::hstore, ARRAY['b','c','x']) → "b"=>"2", "c"=>"3"`

`each ( hstore ) → setof record ( key text, value text )`
Extracts an `hstore`'s keys and values as a set of records.
`select * from each('a=>1,b=>2') →`

```
 key | value
-----+-------
 a   | 1
 b   | 2
```

`exist ( hstore, text ) → boolean`
Does `hstore` contain key?
`exist('a=>1', 'a') → t`

`defined ( hstore, text ) → boolean`
Does `hstore` contain a non-`NULL` value for key?
`defined('a=>NULL', 'a') → f`

`delete ( hstore, text ) → hstore`
Deletes pair with matching key.
`delete('a=>1,b=>2', 'b') → "a"=>"1"`

`delete ( hstore, text[] ) → hstore`
Deletes pairs with matching keys.
`delete('a=>1,b=>2,c=>3', ARRAY['a','b']) → "c"=>"3"`

`delete ( hstore, hstore ) → hstore`
Deletes pairs matching those in the second argument.
`delete('a=>1,b=>2', 'a=>4,b=>2'::hstore) → "a"=>"1"`

`populate_record ( anyelement, hstore ) → anyelement`

Function Description Example(s)	
Replaces fields in the left operand (which must be a composite type) with matching values from `hstore`. `populate_record(ROW(1,2), 'f1=>42'::hstore)` → `(42,2)`	

In addition to these operators and functions, values of the `hstore` type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type `text` can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h['a'] FROM mytable;
 h
---
 b
(1 row)

UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;
          h
----------------------
 "a"=>"b", "c"=>"new"
(1 row)
```

A subscripted fetch returns `NULL` if the subscript is `NULL` or that key does not exist in the `hstore`. (Thus, a subscripted fetch is not greatly different from the `->` operator.) A subscripted update fails if the subscript is `NULL`; otherwise, it replaces the value for that key, adding an entry to the `hstore` if the key does not already exist.

F.26.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);

CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);

CREATE INDEX hidx ON testhstore USING HASH (h);
```

F.26.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h['c'] = '3';
```

Another way to do the same thing is:

```
UPDATE tab SET h = h || hstore('c', '3');
```

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscripting:

```
UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a `record` to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT hstore(t) FROM test AS t;
                   hstore
---------------------------------------------
 "col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an `hstore` to a predefined `record` type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
                              '"col1"=>"456", "col2"=>"zzz"');
 col1 | col2 | col3
------+------+------
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
------+------+------
  123 | foo  | baz
(1 row)
```

F.26.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
```

```
  (SELECT (each(h)).key FROM testhstore) AS stat
  GROUP BY key
  ORDER BY count DESC, key;
    key    | count
-----------+-------
 line      |   883
 query     |   207
 pos       |   203
 node      |   202
 space     |   197
 status    |   195
 public    |   194
 title     |   190
 org       |   189
.................
```

F.26.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

F.26.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperlu`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extension for PL/Python is called `hstore_plpython3u`. If you use it, `hstore` values are mapped to Python dictionaries.

> **Caution**
>
> It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.26.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

F.27. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

Table F.16. Modules

Language	Extension name	Dictionary name	Configuration name
American English	hunspell_en_us	english_hunspell	english_hunspell
Dutch	hunspell_nl_nl	dutch_hunspell	dutch_hunspell
French	hunspell_fr	french_hunspell	french_hunspell
Russian	hunspell_ru_ru	russian_hunspell	russian_hunspell

F.27.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
   alias   |   description   |   token   |          dictionaries           |
 dictionary    |  lexemes
-----------+-----------------+-----------+---------------------------------
+-----------------+-----------
 asciiword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
 english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the `Snowball` dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
               to_tsvector
----------------------------------------
 'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
 ?column?
```

```
----------
 t
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);
INSERT INTO table1 VALUES ('The blue whale is the largest animal');
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)
  @@ to_tsquery('english_hunspell', 'blue & animal');
                  t
-------------------------------------
 The blue whale is the largest animal
(1 row)
```

F.28. hypopg — support for hypothetical indexes

F.28.1. Description

hypopg is a Postgres Pro extension, adding support for *hypothetical indexes*.

A hypothetical, or virtual, index is an index that does not really exist, and therefore does not cost CPU, disk, or any resource to create. They are useful to find out whether specific indexes can increase the performance for problematic queries, since you can discover if Postgres Pro will use these indexes or not without having to spend resources to create them.

F.28.2. Installation

The hypopg extension is provided with Postgres Pro as a separate pre-built package `hypopg-ent-16` (for the detailed installation instructions, see Chapter 17). Once you have Postgres Pro installed, create the hypopg extension:

```
CREATE EXTENSION hypopg;
```

hypopg is now available. You can check easily if the extension is present using psql:

```
\dx
                     List of installed extensions
  Name   | Version |   Schema   |              Description
---------+---------+------------+-----------------------------------
 hypopg  | 1.4.1   | public     | Hypothetical indexes for Postgres Pro
 plpgsql | 1.0     | pg_catalog | PL/pgSQL procedural language
(2 rows)
```

As you can see, hypopg is installed.

F.28.3. Functions

hypopg is useful if you want to check if some index would help one or multiple queries. Therefore, you should already know what are the queries you need to optimize, and ideas on which indexes you want to try.

Also, the hypothetical indexes that hypopg will create are not stored in any catalog, but in your connection private memory. Therefore, it won't bloat any table and won't impact any concurrent connection.

Moreover, since the hypothetical indexes don't really exist, hypopg makes sure they will only be using a simple `EXPLAIN` statement (without the `ANALYZE` option).

The following access methods are supported:

- `btree`
- `brin`
- `hash`
- `bloom` (requires the bloom extension to be installed)

> **Note**
>
> Using hypopg requires some knowledge on the `EXPLAIN` command.

F.28.3.1. Create a Hypothetical Index

`hypopg_create_index()`

For clarity, let's see how it works with a very simple test case:

```
CREATE TABLE hypo (id integer, val text) ;
INSERT INTO hypo SELECT i, 'line ' || i FROM generate_series(1, 100000) i ;
VACUUM ANALYZE hypo ;
```

This table doesn't have any index. Let's assume we want to check if an index would help a simple query. First, let's see how it behaves:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
                        QUERY PLAN
-----------------------------------------------------
 Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=14)
   Filter: (id = 1)
(2 rows)
```

A plain sequential scan is used, since no index exists on the table. A simple btree index on the `id` column should help this query. Let's check with hypopg. The function `hypopg_create_index()` will accept any standard `CREATE INDEX` statement(s) (any other statement passed to this function will be ignored), and create a hypothetical index for each:

```
SELECT * FROM hypopg_create_index('CREATE INDEX ON hypo (id)') ;
 indexrelid |      indexname
------------+----------------------
      18284 | <18284>btree_hypo_id
(1 row)
```

The function returns two columns:

- the object identifier of the hypothetical index
- the generated hypothetical index name

We can run the `EXPLAIN` again to see if Postgres Pro would use this index:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
                                    QUERY PLAN
-----------------------------------------------------------------------------------
 Index Scan using <18284>btree_hypo_id on hypo  (cost=0.04..8.06 rows=1 width=10)
   Index Cond: (id = 1)
(2 rows)
```

Yes, Postgres Pro would use such an index. Just to be sure, let's check that the hypothetical index won't be used to actually run the query:

```
EXPLAIN ANALYZE SELECT val FROM hypo WHERE id = 1;
                                                QUERY PLAN
-----------------------------------------------------------------------------------------------------------
 Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=10) (actual time=0.046..46.390
 rows=1 loops=1)
   Filter: (id = 1)
   Rows Removed by Filter: 99999
 Planning time: 0.160 ms
 Execution time: 46.460 ms
(5 rows)
```

That's all you need to create hypothetical indexes and see if Postgres Pro would use such indexes.

F.28.3.2. Manipulate Hypothetical Indexes

The `hypopg_list_indexes` view lists all hypothetical indexes that have been created.

```
SELECT * FROM hypopg_list_indexes ;
 indexrelid |      index_name       | schema_name | table_name | am_name
------------+-----------------------+-------------+------------+---------
      18284 | <18284>btree_hypo_id  | public      | hypo       | btree
```

```
(1 row)
```

`hypopg()`

`hypopg()` lists all hypothetical indexes that have been created with the same format as `pg_index`.

```
SELECT * FROM hypopg() ;
      indexname       | indexrelid | indrelid | innatts | indisunique | indkey |
 indcollation | indclass | indoption | indexprs | indpred | amid
----------------------+------------+----------+---------+-------------+--------
+--------------+----------+-----------+----------+---------+------
 <18284>btree_hypo_id |      13543 |    18122 |       1 | f           | 1      | 0
          | 1978     | <NULL>    | <NULL>   | <NULL>  |  403
(1 row)
```

`hypopg_get_indexdef(oid)`

`hypopg_get_indexdef(oid)` lists the `CREATE INDEX` statements that would recreate a stored hypothetical index.

```
SELECT index_name, hypopg_get_indexdef(indexrelid) FROM hypopg_list_indexes ;
      index_name       |             hypopg_get_indexdef
-----------------------+---------------------------------------------
 <18284>btree_hypo_id  | CREATE INDEX ON public.hypo USING btree (id)
(1 row)
```

`hypopg_relation_size(oid)`

`hypopg_relation_size(oid)` estimates how big a hypothetical index would be:

```
SELECT index_name, pg_size_pretty(hypopg_relation_size(indexrelid))
  FROM hypopg_list_indexes ;
      index_name       | pg_size_pretty
-----------------------+----------------
 <18284>btree_hypo_id  | 2544 kB
(1 row)
```

`hypopg_drop_index(oid)`

`hypopg_drop_index(oid)` removes the given hypothetical index.

`hypopg_reset()`

`hypopg_reset()` removes all hypothetical indexes.

F.28.3.3. Hypothetically Hide Existing Indexes

`hypopg_hide_index(oid)`

You can hide both existing and hypothetical indexes hypothetically. If you want to test it as described in the documentation, you should first use `hypopg_reset()` to clear the effects of any other hypothetical indexes.

As a simple case, let's consider two indexes:

```
SELECT hypopg_reset();
CREATE INDEX ON hypo(id);
CREATE INDEX ON hypo(id, val);
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
                                  QUERY PLAN
-------------------------------------------------------------------------------
Index Only Scan using hypo_id_val_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

The query plan is using the `hypo_id_val_idx` index now.

`hypopg_hide_index(oid)` allows you to hide an index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully hidden, and false otherwise.

```
SELECT hypopg_hide_index('hypo_id_val_idx'::REGCLASS);
 hypopg_hide_index
-------------------
t
(1 row)

EXPLAIN SELECT * FROM hypo WHERE id = 1;
                              QUERY PLAN
-----------------------------------------------------------------------
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

As an example, let's assume that the query plan is currently using the `hypo_id_val_idx` index. To continue testing, use the `hypopg_hide_index(oid)` function to hide another index.

```
SELECT hypopg_hide_index('hypo_id_idx'::REGCLASS);
 hypopg_hide_index
-------------------
t
(1 row)

EXPLAIN SELECT * FROM hypo WHERE id = 1;
                      QUERY PLAN
-------------------------------------------------------
Seq Scan on hypo  (cost=0.00..180.00 rows=1 width=13)
Filter: (id = 1)
(2 rows)
```

`hypopg_unhide_index(oid)`

`hypopg_unhide_index(oid)` restores a previously hidden index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully restored, and false otherwise.

```
SELECT hypopg_unhide_index('hypo_id_idx'::regclass);
 hypopg_unhide_index
---------------------
t
(1 row)

EXPLAIN SELECT * FROM hypo WHERE id = 1;
                              QUERY PLAN
-----------------------------------------------------------------------
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

`hypopg_unhide_all_index(oid)`

`hypopg_unhide_all_index()` restores all hidden indexes and returns `void`.

`hypopg_hidden_indexes()`

`hypopg_hidden_indexes()` returns a list of OIDs for all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes();
 indexid
```

```
---------
526604
(1 rows)
```

The `hypopg_hidden_indexes` view returns a formatted list of all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes;
  indexrelid |      index_name      | schema_name | table_name | am_name | is_hypo
-------------+----------------------+-------------+------------+---------+---------
      526604 | hypo_id_val_idx      | public      | hypo       | btree   | f
(1 rows)
```

> **Note**
>
> Hypothetical indexes can be hidden as well.

```
SELECT hypopg_create_index('CREATE INDEX ON hypo(id)');
    hypopg_create_index
-----------------------------
(12659,<12659>btree_hypo_id)
(1 row)

EXPLAIN SELECT * FROM hypo WHERE id = 1;
                                  QUERY PLAN
-------------------------------------------------------------------------------
Index Scan using "<12659>btree_hypo_id" on hypo  (cost=0.04..8.05 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

Now that the hypothetical index is being used, we can try hiding it to see the change:

```
SELECT hypopg_hide_index(12659);
 hypopg_hide_index
-------------------
t
(1 row)

EXPLAIN SELECT * FROM hypo WHERE id = 1;
                            QUERY PLAN
------------------------------------------------------------------
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)

SELECT * FROM hypopg_hidden_indexes;
  indexrelid |      index_name      | schema_name | table_name | am_name | is_hypo
-------------+----------------------+-------------+------------+---------+---------
       12659 | <12659>btree_hypo_id | public      | hypo       | btree   | t
      526604 | hypo_id_val_idx      | public      | hypo       | btree   | f
(2 rows)
```

> **Note**
>
> If a hypothetical index has been hidden, it will be automatically unhidden when it is deleted using `hypopg_drop_index(oid)` or `hypopg_reset()`.

```
SELECT hypopg_drop_index(12659);
```

```
SELECT * FROM hypopg_hidden_indexes;
  indexrelid |      index_name      | schema_name | table_name | am_name | is_hypo
-------------+----------------------+-------------+------------+---------+---------
      526604 | hypo_id_val_idx      | public      | hypo       | btree   | f
(2 rows)
```

F.28.4. GUC Parameters

The following configuration parameters (GUCs) are available, and can be changed interactively:

`hypopg.enabled`

Defaults to `on`. Use this parameter to globally enable or disable hypopg. When hypopg is disabled, no hypothetical index will be used, but the defined hypothetical indexes won't be removed.

`hypopg.use_real_oids`

Defaults to `off`. By default, hypopg won't use "real" object identifiers, but instead borrow ones from the ~ 14000 / 16384 (respectively the lowest unused OID less then `FirstNormalObjectId` and `FirstNormalObjectId`) range, which are reserved by Postgres Pro for future usage in future releases. This doesn't cause any problem, as the free range is dynamically computed the first time a connection uses hypopg, and has the advantage to work on a standby server. But the drawback is that you can't have more than approximately 2500 hypothetical indexes at the same time, and creating a new hypothetical index will become very slow once more than the maximum number of objects has been created until `hypopg_reset()` is called.

If those drawbacks are problematic, you can enable this parameter. hypopg will then ask for a real object identifier, which will need to obtain more locks and won't work on a standby, but will allow using the full range of object identifiers.

Note that switching this parameter doesn't require resetting the entries, both can coexist at the same time.

F.29. in_memory — store data in shared memory using tables implemented via FDW

The in_memory extension enables you to store data in Postgres Pro shared memory using in-memory tables implemented via foreign data wrappers (FDW).

> **Note**
>
> This extension cannot be used together with prepared transactions or while built-in connection pooling is enabled.

In-memory tables are *index-organized* — table rows are stored in leaf pages of the B-tree index defined on the primary key for the table. This solution offers the following benefits:

- Fast random access on the primary key. This can result in significant performance benefits when working with data that requires a very high read and write access rate, especially on multi-core systems.
- Effective space usage. There is no primary key duplication as all data is stored directly in the index.

In-memory tables support transactions, including savepoints. However, the data in such tables is stored only while the server is running. Once the server is shut down, all in-memory data gets truncated. When using in-memory tables, you should also take into account the following restrictions:

- Persistence, WAL, and data replication are currently not supported for in-memory tables.
- Secondary indexes are not supported.
- Isolation levels are supported up to REPEATABLE READ. SERIALIZABLE isolation level is not supported. REPEATABLE READ level is used instead.
- In-memory tables do not support TOAST or any other mechanism for storing big tuples. Since the in-memory page size is 1 kB, and the B-tree index requires at least three tuples in a page, the maximum row length is limited to 304 bytes.
- When a row is deleted from an in-memory table, the corresponding data page is not freed. See Section F.29.2.3 for details.

F.29.1. Installation and Setup

To enable in-memory tables for your cluster:

1. Make sure that the postgres_fdw module is enabled.
2. Add the in_memory value to the shared_preload_libraries variable in the postgresql.conf file:

   ```
   shared_preload_libraries = 'in_memory'
   ```

3. Create the in_memory extension using the following statement:

   ```
   CREATE EXTENSION in_memory;
   ```

As a result, the in_memory foreign server is created, and a separate shared memory pool is allocated for in-memory tables, with pre-created pages for storing in-memory data. For in-memory tables, smaller locality is required for effective memory access, as compared to hard drives or SSD, so in-memory page size is 1 kB only. Once the extension is created, you can start using in-memory tables as explained in Section F.29.2.

> **Tip**
>
> If required, you can increase the memory size allocated for in-memory tables. For details, see Section F.29.2.6.

F.29.2. Usage

F.29.2.1. Creating In-Memory Tables

To add an in-memory table to your database, create a foreign table on the `in_memory` server, using the regular CREATE FOREIGN TABLE syntax. By default, a unique B-tree index is built upon the first column, in the ascending order. If required, you can use the `INDICES` option in the `OPTIONS` clause to define a different B-tree index structure, as follows:

```
OPTIONS ( INDICES '[ UNIQUE ] {column [ COLLATE collation ] [ASC | DESC] } [, ... ]' )
```

where *`column`* is the column to include into the B-tree index, and *`collation`* is the name of the collation to use for this column. You can specify up to eight arbitrary columns separated by commas, with sorting options defined for each of these columns (`COLLATE`, `ASC`/`DESC`). The `UNIQUE` declares the created index unique, reiterating the default behavior.

All columns to be used in the B-tree index must be of a type for which the default B-tree operator class is available. For details on operator classes, see Section 11.10.

Examples

Create an in-memory table `blog_views` to store statistics on blog views based on blog post IDs, with the unique B-tree index built upon the first column, in the ascending order:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory
OPTIONS (INDICES 'UNIQUE (id)');
```

Define the B-tree index on the `id` and `author` columns, with the `author` values sorted in the ascending order using `"ru_RU"` collation:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory
OPTIONS (INDICES '(id, author COLLATE "ru_RU" ASC)');
```

F.29.2.2. Running Queries on In-Memory Tables

Once an in-memory table is created, you can run all the main DML operations on this table: `SELECT`, `INSERT`, `UPDATE`, `DELETE`.

If you use the primary key as the scan qualifier when running queries, a key lookup or range scan is performed. Otherwise, a full index scan is required.

Examples

Fill the `blog_views` table with initial zero values for initial ten blog posts:

```
postgres=# INSERT INTO blog_views (SELECT id, 0 FROM generate_series(1, 10) AS id);
```

Increment the view count for a couple of posts and display the result:

```
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 1
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 2
```

```
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 2;
UPDATE 1
postgres=# SELECT * FROM blog_views WHERE id = 1 OR id = 2;
 id | views
----+-------
  1 |  2
  2 |  1
(2 rows)
```

Check planning and execution costs for a query that only requires a primary key lookup:

```
postgres=# EXPLAIN ANALYZE SELECT * FROM blog_views WHERE id = 1;
                        QUERY PLAN
-----------------------------------------------------------------------
Foreign Scan on blog_views  (cost=0.02..0.03 rows=1 width=16)
(actual time=0.013..0.014 rows=1 loops=1)
  Pk conds: (id = 1)
Planning time: 0.060 ms
Execution time: 0.035 ms
(4 rows)
```

Check the costs of calculating the sum of all views, which requires a full index scan:

```
postgres=# EXPLAIN ANALYZE SELECT SUM(views) FROM blog_views;
                          QUERY PLAN
---------------------------------------------------------------------------
Aggregate  (cost=1.62..1.63 rows=1 width=32)
(actual time=0.323..0.323 rows=1 loops=1)
Foreign Scan on blog_views  (cost=0.02..1.30 rows=128 width=8)
(actual time=0.005..0.168 rows=1000 loops=1)
Planning time: 0.113 ms
Execution time: 0.353 ms
(4 rows)
```

F.29.2.3. Deleting In-Memory Data

When a row is deleted from an in-memory table, data pages are not freed. To free the pages occupied by in-memory tables, you can:

- Delete the table using the `DROP FOREIGN TABLE` command.
- Truncate the table using the `TRUNCATE` command.

`RESTART IDENTITY`, `CONTINUE IDENTITY`, `CASCADE`, and `RESTRICT` options of the `TRUNCATE` command are not supported by in-memory tables.

F.29.2.4. Writing Data to In-Memory Tables on Hot Standby

In some cases, it can be useful to perform write operations on hot standby servers. For example, suppose you need to collect statistics on queries run on hot standby. Since in-memory tables are writable, you can use them for such purposes.

To set up in-memory tables for write queries on standby, create the required in-memory tables on the primary server as explained in Section F.29.2.1. Once the replication is complete, you can start writing data to these tables on hot standby.

> **Important**
>
> If the hot standby server is restarted, all the data stored in its in-memory tables gets truncated. You can continue writing data to the same in-memory tables, but all the previously stored data will be lost.

F.29.2.5. Getting Statistics on In-Memory Tables

To get statistics on in-memory pages available in your cluster, run the in_memory_page_stats function, which returns the number of all used and free in-memory pages, as well as the total number of pages allocated for in-memory tables. For example:

```
postgres=# SELECT * FROM in_memory.in_memory_page_stats();
 busy_pages | free_pages | all_pages
------------+------------+-----------
        576 |       7616 |      8192
(1 row)
```

F.29.2.6. Fine-Tuning Memory Settings

F.29.2.6.1. Increasing Shared Memory Pool for In-Memory Tables

In-memory tables are stored in a separate shared memory segment. Its size is defined by the `in_memory.shared_pool_size` parameter. By default, this memory segment is limited to 8 MB.

If the data to be stored in in-memory tables exceeds the size of the allocated memory segment, the following error occurs:

```
ERROR: failed to get a new page: shared pool size is exceeded
```

To avoid such issues, you can increase the `in_memory.shared_pool_size` value, or limit the size of the stored data. Changing the shared pool size requires a server restart.

F.29.2.6.2. Managing the Undo Log

To enable multi-version concurrency control (MVCC), the `in_memory` module uses the *undo log* — a shared-memory ring buffer that stores the previous versions of data entries and pages. The size of the undo log is defined by the `in_memory.undo_size` parameter and is limited to 1 MB by default. If a buffer overflow occurs before a transaction is complete, the following error is returned:

```
ERROR: failed to add undo record: undo size is exceeded
```

To avoid this issue, you can increase the `in_memory.undo_size` value, or split the transactions into smaller ones.

If the required version of the entry or page has already been overwritten in the undo log when it is accessed for read, the following error occurs:

```
ERROR: snapshot is outdated
```

In this case, you can:

- Increase the `in_memory.undo_size` value. Changing this parameter requires a server restart.
- Ensure that the undo log is not truncated while the snapshot is in use. To achieve this, you can use the `READ COMMITTED` isolation level, or split a complex query into several smaller ones.

F.29.3. Reference

F.29.3.1. Configuration Variables

`in_memory.shared_pool_size` (`integer`)

Defines the size of the shared memory segment allocated for in-memory tables.

Default: 8MB

`in_memory.undo_size` (`integer`)

Defines the size of the undo log.

Default: 1MB

F.29.3.2. Functions

`in_memory.in_memory_page_stats()`

Displays statistics on pages of in-memory tables:

- `busy_pages` — in-memory pages containing any data.
- `free_pages` — empty in-memory pages. This number includes all the initially allocated pages to which no data has been written yet, as well as the pages from which all data has been deleted.
- `all_pages` — the total number of in-memory pages allocated on this server.

F.29.4. Authors

Postgres Professional, Moscow, Russia

F.30. intagg — integer aggregator and enumerator

The intagg module provides an integer aggregator and an enumerator. intagg is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.30.1. Functions

The aggregator is an aggregate function int_array_aggregate(integer) that produces an integer array containing exactly the integers it is fed. This is a wrapper around array_agg, which does the same thing for any array type.

The enumerator is a function int_array_enum(integer[]) that returns setof integer. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around unnest, which does the same thing for any array type.

F.30.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
  WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the one_to_many table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
  GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using int_array_enum produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against one_to_many must index scan and fetch a row for each entry.

On one system, an EXPLAIN showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the one_to_many table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
         ON (summary.left = lefts.left)
  ) AS list
  GROUP BY right
```

```
    ORDER BY count DESC;
```

F.31. intarray — manipulate arrays of integers

The intarray module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.31.1. intarray Functions and Operators

The functions provided by the intarray module are shown in Table F.17, the operators in Table F.18.

Table F.17. intarray Functions

Function Description Example(s)
icount (integer[]) → integer Returns the number of elements in the array. icount('{1,2,3}'::integer[]) → 3
sort (integer[], *dir* text) → integer[] Sorts the array in either ascending or descending order. *dir* must be asc or desc. sort('{1,3,2}'::integer[], 'desc') → {3,2,1}
sort (integer[]) → integer[] sort_asc (integer[]) → integer[] Sorts in ascending order. sort(array[11,77,44]) → {11,44,77}
sort_desc (integer[]) → integer[] Sorts in descending order. sort_desc(array[11,77,44]) → {77,44,11}
uniq (integer[]) → integer[] Removes adjacent duplicates. Often used with sort to remove all duplicates. uniq('{1,2,2,3,1,1}'::integer[]) → {1,2,3,1} uniq(sort('{1,2,3,2,1}'::integer[])) → {1,2,3}
idx (integer[], *item* integer) → integer Returns index of the first array element matching *item*, or 0 if no match. idx(array[11,22,33,22,11], 22) → 2
subarray (integer[], *start* integer, *len* integer) → integer[] Extracts the portion of the array starting at position *start*, with *len* elements. subarray('{1,2,3,2,1}'::integer[], 2, 3) → {2,3,2}
subarray (integer[], *start* integer) → integer[] Extracts the portion of the array starting at position *start*. subarray('{1,2,3,2,1}'::integer[], 2) → {2,3,2,1}
intset (integer) → integer[] Makes a single-element array. intset(42) → {42}

Table F.18. `intarray` Operators

Operator Description
`integer[] && integer[]` → `boolean` Do arrays overlap (have at least one element in common)?
`integer[] @> integer[]` → `boolean` Does left array contain right array?
`integer[] <@ integer[]` → `boolean` Is left array contained in right array?
`# integer[]` → `integer` Returns the number of elements in the array.
`integer[] # integer` → `integer` Returns index of the first array element matching the right argument, or 0 if no match. (Same as `idx` function.)
`integer[] + integer` → `integer[]` Adds element to end of array.
`integer[] + integer[]` → `integer[]` Concatenates the arrays.
`integer[] - integer` → `integer[]` Removes entries matching the right argument from the array.
`integer[] - integer[]` → `integer[]` Removes elements of the right array from the left array.
`integer[] | integer` → `integer[]` Computes the union of the arguments.
`integer[] | integer[]` → `integer[]` Computes the union of the arguments.
`integer[] & integer[]` → `integer[]` Computes the intersection of the arguments.
`integer[] @@ query_int` → `boolean` Does array satisfy query? (see below)
`query_int ~~ integer[]` → `boolean` Does array satisfy query? (commutator of `@@`)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1&(2|3)` matches arrays that contain 1 and also contain either 2 or 3.

F.31.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more

suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.31.3. Example

```
-- a message can be in one or more “sections”
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
 (siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

F.31.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See *http://www.sai.msu.su/~megera/postgres/gist/* for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.32. isn — data types for international standard numbers (ISBN, EAN, UPC, etc.)

The isn module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.32.1. Data Types

Table F.19 shows the data types provided by the isn module.

Table F.19. isn Data Types

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The ISBN, ISMN, and ISSN types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The EAN13, ISBN13, ISMN13 and ISSN13 types will always display the long version of the ISxN (EAN13).

F.32.2. Casts

The isn module provides the following pairs of type casts:

- ISBN13 <=> EAN13
- ISMN13 <=> EAN13
- ISSN13 <=> EAN13
- ISBN <=> EAN13
- ISMN <=> EAN13
- ISSN <=> EAN13
- UPC <=> EAN13
- ISBN <=> ISBN13
- ISMN <=> ISMN13
- ISSN <=> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.32.3. Functions and Operators

The isn module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F.20. In this table, isn means any one of the module's data types.

Table F.20. isn Functions

Function Description
isn_weak (boolean) → boolean Sets the weak input mode, and returns new setting.
isn_weak () → boolean Returns the current status of the weak mode.
make_valid (isn) → isn Validates an invalid number (clears the invalid flag).
is_valid (isn) → boolean Checks for the presence of the invalid flag.

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (`!`) at the end, for example `0-11-000322-5!`. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

F.32.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

F.32.5. Bibliography

The information to implement this module was collected from several sites, including:

- *https://www.isbn-international.org/*
- *https://www.issn.org/*
- *https://www.ismn-international.org/*

- *https://www.wikipedia.org/*

The prefixes used for hyphenation were also compiled from:

- *https://www.gs1.org/standards/id-keys*
- *https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups*
- *https://www.isbn-international.org/content/isbn-users-manual/29*
- *https://en.wikipedia.org/wiki/International_Standard_Music_Number*
- *https://www.ismn-international.org/ranges/tools*

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.32.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

F.33. jsquery — a language to query jsonb data type

JsQuery is a language to query jsonb data type. Its primary goal is to provide an additional functionality for jsonb, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

JsQuery is implemented by means of a jsquery data type (similar to tsquery) and the @@ match operator for jsonb.

F.33.1. Installation

Postgres Pro Enterprise distribution includes jsquery as a contrib module. Once you complete Postgres Pro Enterprise installation, create the jsquery extension, as follows:

```
CREATE EXTENSION jsquery;
```

F.33.2. JSON query language

JsQuery extension contains jsquery datatype which represents whole JSON query as a single value (like tsquery does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary_operator value* or *path unary_operator*. See the following examples.

- x = "abc" - value of key "x" is equal to "abc";
- $ @> [4, 5, "zzz"] - the JSON document is an array containing values 4, 5 and "zzz";
- "abc xyz" >= 10 - value of key "abc xyz" is greater than or equal to 10;
- volume IS NUMERIC - type of key "volume" is numeric.
- $ = true - the whole JSON document is just a true.
- similar_ids.@# > 5 - similar_ids is an array or object of length greater than 5;
- similar_product_ids.# = "0684824396" - array similar_product_ids contains string "0684824396".
- *.color = "red" - there is object somewhere which key "color" has value "red".
- foo = * - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- # - any index of array;
- #N - Nth index of array;
- % - any key of object;
- * - any sequence of array indexes and object keys;
- @# - length of array or object, could be only used as last component of path;
- $ - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jsquery keyword.

The supported binary operators are:

- Equality operator: =;
- Numeric comparison operators: >, >=, <, <=;
- Search in the list of scalar values using IN operator;
- Array comparison operators: && (overlap), @> (contains), <@ (contained in).
- Filtering operator: ~~. Taking jsonb data as the left operand and a jsquery expression as the right operand, this operator checks that jsonb data contains any entries that satisfy the condition provided in a jsquery expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form path (subexpression). In this case path selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 2 and the `b` key is 2
- `%($ >= 10 AND $ <= 20)` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*:` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:($ >= 0 AND $ <= 1)
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:($ >= 0 AND $ <= 1))
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ($ >= 0 AND $ <= 1)) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:($ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#:.%:($ >= 0 AND $ <= 1)` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#: ($ IS STRING)` - JSON object contains at least one array of strings.
- `#.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.

- `#($ < 10 AND $ > 20)` - there is an element that is both less than 10 and greater than 20 (impossible).
- `#($ >= 10 AND $ <= 20)` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance [0,30].

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JsQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (
    id serial,
    data jsonb,
    CHECK (data @@ '
        name IS STRING AND
        similar_ids.#: IS NUMERIC AND
        points.#:(x IS NUMERIC AND y IS NUMERIC)'::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our *pgconf.eu presentation* for more examples.

F.33.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- jsonb_path_value_ops
- jsonb_value_path_ops

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{"a": [{"b": "xyz", "c": true}, 10], "d": {"e": [7, false]}}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since JsQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same `#` sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.33.3.1. jsonb_path_value_ops

jsonb_path_value_ops represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full

path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.33.3.2. jsonb_value_path_ops

jsonb_value_path_ops represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing `%` and `*` in their paths.

F.33.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- gin_debug_query_path_value(jsquery) - for jsonb_path_value_ops
- gin_debug_query_value_path(jsquery) - for jsonb_value_path_ops

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
 gin_debug_query_path_value
----------------------------
 x = 1 , entry 0           +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
 gin_debug_query_value_path
----------------------------
 AND                       +
   x = 1 , entry 0         +
   OR                      +
     *.y = 1 , entry 1     +
     y = 2 , entry 2       +
```

Unfortunately, jsonb has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality (x = c)
2. Range (c1 < x < c2)
3. Inequality (x > c)
4. Is (x is type)
5. Any (x = *)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the `x = 1 AND y > 0` query `x = 1` is assumed to be more selective than `y > 0`. That's why index isn't used for evaluation of `y > 0`.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
 gin_debug_query_path_value
----------------------------
 x = 1 , entry 0           +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JsQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
 gin_debug_query_path_value
----------------------------
 AND                       +
   x = 1 , entry 0         +
   y > 0 , entry 1         +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
 gin_debug_query_path_value
----------------------------
  y > 0 , entry 0           +
```

F.34. lo — manage large objects

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.34.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large OBjects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a *domain* over the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

F.34.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF` *`column_name`*. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.34.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM` *`table`*.

  `TRUNCATE` has the same hazard.

  If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It's a good idea to run vacuumlo occasionally as a back-stop to the `lo_manage` trigger.
- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

F.35. ltree — hierarchical tree-like data type

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.35.1. Definitions

A *label* is a sequence of alphanumeric characters, underscores, and hyphens. Valid alphanumeric character ranges are dependent on the database locale. For example, in C locale, the characters `A-Za-z0-9_-` are allowed. Labels must be no more than 1000 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

  ```
  foo         Match the exact label path foo
  *.foo.*     Match any label path containing the label foo
  *.foo       Match any label path whose last label is foo
  ```

  Both star symbols and simple words can be quantified to restrict how many labels they can match:

  ```
  *{n}        Match exactly n labels
  *{n,}       Match at least n labels
  *{n,m}      Match at least n but not more than m labels
  *{,m}       Match at most m labels — same as *{0,m}
  foo{n,m}    Match at least n but not more than m occurrences of foo
  foo{,}      Match any number of occurrences of foo, including zero
  ```

  In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

  There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

  ```
  @           Match case-insensitively, for example a@ matches A
  *           Match any label with this prefix, for example foo* matches foobar
  %           Match initial underscore-separated words
  ```

  The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

  Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means

some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.     c.      d.                   e.
```

This query will match any label path that:

a. begins with the label `Top`

b. and next has zero to two labels before

c. a label beginning with the case-insensitive prefix `sport`

d. then has one or more labels, none of which match `football` nor `tennis`

e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.

- `ltxtquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxtquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxtquery` matches words without regard to their position in the label path.

  Here's an example `ltxtquery`:

  ```
  Europe & Russia*@ & !Transportation
  ```

  This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxtquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.35.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F.21 are available.

Table F.21. `ltree` Operators

Operator Description
`ltree @> ltree → boolean` Is left argument an ancestor of right (or equal)?
`ltree <@ ltree → boolean` Is left argument a descendant of right (or equal)?
`ltree ~ lquery → boolean` `lquery ~ ltree → boolean` Does `ltree` match `lquery`?
`ltree ? lquery[] → boolean` `lquery[] ? ltree → boolean` Does `ltree` match any `lquery` in array?
`ltree @ ltxtquery → boolean` `ltxtquery @ ltree → boolean` Does `ltree` match `ltxtquery`?

Operator Description
`ltree || ltree → ltree` Concatenates `ltree` paths.
`ltree || text → ltree` `text || ltree → ltree` Converts text to `ltree` and concatenates.
`ltree[] @> ltree → boolean` `ltree <@ ltree[] → boolean` Does array contain an ancestor of `ltree`?
`ltree[] <@ ltree → boolean` `ltree @> ltree[] → boolean` Does array contain a descendant of `ltree`?
`ltree[] ~ lquery → boolean` `lquery ~ ltree[] → boolean` Does array contain any path matching `lquery`?
`ltree[] ? lquery[] → boolean` `lquery[] ? ltree[] → boolean` Does `ltree` array contain any path matching any `lquery`?
`ltree[] @ ltxtquery → boolean` `ltxtquery @ ltree[] → boolean` Does array contain any path matching `ltxtquery`?
`ltree[] ?@> ltree → ltree` Returns first array entry that is an ancestor of `ltree`, or `NULL` if none.
`ltree[] ?<@ ltree → ltree` Returns first array entry that is a descendant of `ltree`, or `NULL` if none.
`ltree[] ?~ lquery → ltree` Returns first array entry that matches `lquery`, or `NULL` if none.
`ltree[] ?@ ltxtquery → ltree` Returns first array entry that matches `ltxtquery`, or `NULL` if none.

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in Table F.22.

Table F.22. `ltree` Functions

Function Description Example(s)
`subltree ( ltree, start integer, end integer ) → ltree` Returns subpath of `ltree` from position *start* to position *end*-1 (counting from 0). `subltree('Top.Child1.Child2', 1, 2)` → `Child1`
`subpath ( ltree, offset integer, len integer ) → ltree` Returns subpath of `ltree` starting at position *offset*, with length *len*. If *offset* is negative, subpath starts that far from the end of the path. If *len* is negative, leaves that many labels off the end of the path.

Function Description Example(s)
`subpath('Top.Child1.Child2', 0, 2)` → `Top.Child1`
`subpath` (`ltree`, *`offset`* `integer`) → `ltree` Returns subpath of `ltree` starting at position *`offset`*, extending to end of path. If *`offset`* is negative, subpath starts that far from the end of the path. `subpath('Top.Child1.Child2', 1)` → `Child1.Child2`
`nlevel` (`ltree`) → `integer` Returns number of labels in path. `nlevel('Top.Child1.Child2')` → `3`
`index` (*`a`* `ltree`, *`b`* `ltree`) → `integer` Returns position of first occurrence of *`b`* in *`a`*, or -1 if not found. `index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6')` → `6`
`index` (*`a`* `ltree`, *`b`* `ltree`, *`offset`* `integer`) → `integer` Returns position of first occurrence of *`b`* in *`a`*, or -1 if not found. The search starts at position *`offset`*; negative *`offset`* means start *`-offset`* labels from the end of the path. `index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4)` → `9`
`text2ltree` (`text`) → `ltree` Casts `text` to `ltree`.
`ltree2text` (`ltree`) → `text` Casts `ltree` to `text`.
`lca` (`ltree` [, `ltree` [, ...]]) → `ltree` Computes longest common ancestor of paths (up to 8 arguments are supported). `lca('1.2.3', '1.2.3.4.5.6')` → `1.2`
`lca` (`ltree[]`) → `ltree` Computes longest common ancestor of paths in array. `lca(array['1.2.3'::ltree,'1.2.3.4'])` → `1.2`

F.35.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

  `gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines)) up to 2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

  Example of creating such an index with the default signature length of 8 bytes:

  ```
  CREATE INDEX path_gist_idx ON test USING GIST (path);
  ```

  Example of creating such an index with a signature length of 100 bytes:

  ```
  CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
  ```

- GiST index over `ltree[]` (`gist__ltree_ops` opclass): `ltree[] <@ ltree`, `ltree @> ltree[]`, `@`, `~`, `?`

`gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path
 gist__ltree_ops(siglen=100));
```

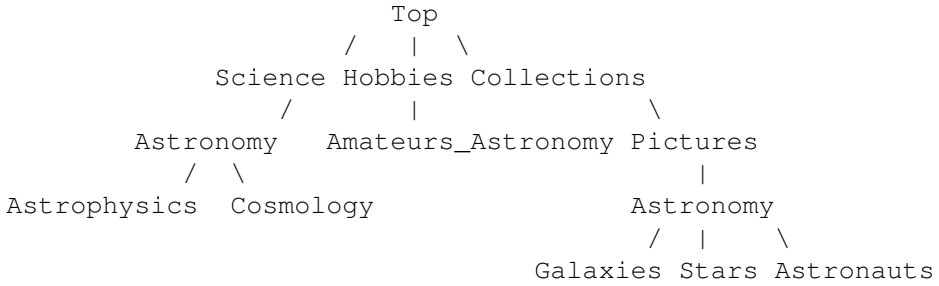
Note: This index type is lossy.

F.35.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:



We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
                path
-----------------------------------
 Top.Science
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
```

```
                     path
-----------------------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
 Top.Collections.Pictures.Astronomy
 Top.Collections.Pictures.Astronomy.Stars
 Top.Collections.Pictures.Astronomy.Galaxies
 Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)

ltreetest=> SELECT path FROM test WHERE path ~ '*.!pictures@.Astronomy.*';
                path
-----------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
                path
-----------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
 Top.Hobbies.Amateurs_Astronomy
(4 rows)

ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
                path
-----------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@
 'Top.Science.Astronomy';
                 ?column?
-----------------------------------------
 Top.Science.Space.Astronomy
 Top.Science.Space.Astronomy.Astrophysics
 Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
    AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'

F.35.5. Transforms

The `ltree_plpython3u` extension implements transforms for the `ltree` type for PL/Python. If installed and specified when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

> **Caution**
>
> It is strongly recommended that the transform extension be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.35.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See *http://www.sai.msu.su/~megera/postgres/gist/* for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.36. mchar — additional data types for compatibility with Microsoft SQL Server

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

F.36.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types MCHAR and MVARCHAR, which are bug-to-bug compatible with MS SQL CHAR and VARCHAR respectively. Additionally, these types use the ICU library for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes citext extension which provides types similar to MCHAR. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard CHAR and VARCHAR are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

F.36.2. Additional types

- `mchar` — analog of the MS SQL char type
- `mvarchar` — analog of the MS SQL varchar type

F.36.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (mchar and mvarchar) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (ICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (ICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The ~ operator (POSIX regexp) support
- Index support for the *LIKE* operator

F.36.4. Authors

F.37. multimaster — synchronous cluster to provide OLTP scalability and high availability

`multimaster` is a Postgres Pro Enterprise extension with a set of patches that turns Postgres Pro Enterprise into a synchronous shared-nothing cluster to provide Online Transaction Processing (OLTP) scalability for read transactions and high availability with automatic disaster recovery.

As compared to a standard PostgreSQL primary-standby cluster, a cluster configured with the `multimaster` extension offers the following benefits:

- Fault tolerance and automatic node recovery
- Synchronous logical replication and DDL replication
- Read scalability
- Working with temporary tables on each cluster node (with limitations)
- Upgrading minor releases of Postgres Pro Enterprise seamlessly for multimaster cluster clients

> **Important**
>
> Before deploying `multimaster` on production systems, make sure to take its replication restrictions into account. For details, see Section F.37.1.

The `multimaster` extension replicates your database to all nodes of the cluster and allows write transactions on each node. Write transactions are synchronously replicated to all nodes, which increases commit latency. Read-only transactions and queries are executed locally, without any measurable overhead.

To ensure high availability and fault tolerance of the cluster, `multimaster` determines each transaction outcome through Paxos consensus algorithm, uses custom recovery protocol and heartbeats for failure discovery. A multi-master cluster of *N* nodes can continue working while the majority of the nodes are alive and reachable by other nodes. To be configured with `multimaster`, the cluster must include at least three nodes. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes. There is also a special 2+1 (referee) mode in which 2 nodes hold data and an additional one called *referee* only participates in voting. Compared to traditional three nodes setup, this is cheaper (referee resources demands are low) but availability is decreased. For details, see Section F.37.3.3.

When a failed node is reconnected to the cluster, `multimaster` automatically fast-forwards the node to the actual state based on the Write-Ahead Log (WAL) data in the corresponding replication slot. If a node was excluded from the cluster, you can add it back using pg_basebackup.

To learn more about the `multimaster` internals, see Section F.37.2.

F.37.1. Limitations

The `multimaster` extension takes care of the database replication in a fully automated way. You can perform write transactions on any node and work with temporary tables on each cluster node simultaneously. However, make sure to take the following replication restrictions into account:

- Microsoft Windows operating system is not supported.
- 1C solutions are not supported.
- `multimaster` can replicate only one database in a cluster. If it is required to replicate the contents of several databases, you can either transfer all data into different schemas within a single database or create a separate cluster for each database and set up `multimaster` for each cluster.
- Large objects are not supported. Although creating large objects is allowed, multimaster cannot replicate such objects, and their OIDs may conflict on different nodes, so their use is not recommended.

- Since multimaster is based on logical replication and Paxos over three-phase commit protocol, its operation is highly affected by network latency. It is not recommended to set up a multimaster cluster with geographically distributed nodes.
- Using tables without primary keys can have negative impact on performance. In some cases, it can even lead to inability to restore a cluster node, so you should avoid replicating such tables with multimaster.
- Unlike in vanilla PostgreSQL, read committed isolation level can cause serialization failures on a multi-master cluster (with an SQLSTATE code '40001') if there are conflicting transactions from different nodes, so the application must be ready to retry transactions. *Serializable* isolation level works only with respect to local transactions on the current node.
- Sequence generation. To avoid conflicts between unique identifiers on different nodes, multimaster modifies the default behavior of sequence generators. By default, ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly. Thus, the generated sequence values are not monotonic. If it is critical to get a monotonically increasing sequence cluster-wide, you can set the multimaster.monotonic_sequences to true.
- Commit latency. In the current implementation of logical replication, multimaster sends data to subscriber nodes only after the local commit, so you have to wait for transaction processing twice: first on the local node, and then on all the other nodes simultaneously. In the case of a heavy-write transaction, this may result in a noticeable delay.
- Logical replication does not guarantee that a system object OID is the same on all cluster nodes, so OIDs for the same object may differ between multimaster cluster nodes. If your driver or application relies on OIDs, make sure that their use is restricted to connections to one and the same node to avoid errors. For example, the Npgsql driver may not work correctly with multimaster if the NpgsqlConnection.GlobalTypeMapper method tries using OIDs in connections to different cluster nodes.
- A multimaster cluster node cannot function as a logical replication subscriber. While a multimaster node can function as a publisher, the subscription cannot automatically switch to another node if the node fails.
- Replicated non-conflicting transactions are applied on the receiving nodes in parallel, so such transactions may become visible on different nodes in different order.
- CREATE INDEX CONCURRENTLY, REINDEX CONCURRENTLY, CREATE TABLESPACE, and DROP TABLESPACE are not supported.
- COMMIT AND CHAIN feature is not supported.
- CREATE [TEMP] TABLE AS is not supported with queries that contain explicit use of variables or arguments of functions or procedures (if the command is executed in the context of a function or procedure), and other context-sensitive objects. It is not recommended to use CREATE TABLE AS with the WITH DATA clause (data copy) in a query that uses temporary tables as it may cause the new table data synchronization issues across cluster nodes.

F.37.2. Architecture

F.37.2.1. Replication

Since each server in a multi-master cluster can accept writes, any server can abort a transaction because of a concurrent update — in the same way as it happens on a single server between different backends. To ensure high availability and data consistency on all cluster nodes, multimaster uses logical replication and the three-phase commit protocol with transaction outcome determined by Paxos consensus algorithm.

When Postgres Pro Enterprise loads the multimaster shared library, multimaster sets up a logical replication producer and consumer for each node, and hooks into the transaction commit pipeline. The typical data replication workflow consists of the following phases:

1. PREPARE phase. multimaster captures and implicitly transforms each COMMIT statement to a PREPARE statement. All the nodes that get the transaction via the replication protocol (*the cohort nodes*) send their vote for approving or declining the transaction to the backend process on the initiating node. This ensures that all the cohort can accept the transaction, and no write conflicts occur. For details on PREPARE transactions support in PostgreSQL, see the PREPARE TRANSACTION topic.
2. PRECOMMIT phase. If all the cohort nodes approve the transaction, the backend process sends a PRECOMMIT message to all the cohort nodes to express an intention to commit the transaction. The cohort nodes respond to the backend with the PRECOMMITTED message. In case of a failure, all the nodes can use this information to complete the transaction using a quorum-based voting procedure.
3. COMMIT phase. If PRECOMMIT is successful, the transaction is committed to all nodes.

If a node crashes or gets disconnected from the cluster between the PREPARE and COMMIT phases, the PRECOMMIT phase ensures that the survived nodes have enough information to complete the prepared transaction. The PRECOMMITTED messages help avoid the situation when the crashed node has already committed or aborted the transaction, but has not notified other nodes about the transaction status. In a two-phase commit (2PC), such a transaction would block resources (hold locks) until the recovery of the crashed node. Otherwise, data inconsistencies can appear in the database when the failed node is recovered, for example, if the failed node committed the transaction, but the survived node aborted it.

To complete the transaction, the backend must receive a response from the majority of the nodes. For example, for a cluster of $2N+1$ nodes, at least $N+1$ responses are required. Thus, multimaster ensures that your cluster is available for reads and writes while the majority of the nodes are connected, and no data inconsistencies occur in case of a node or connection failure.

F.37.2.2. Failure Detection and Recovery

Since multimaster allows writes to each node, it has to wait for responses about transaction acknowledgment from all the other nodes. Without special actions in case of a node failure, each commit would have to wait until the failed node recovery. To deal with such situations, multimaster periodically sends heartbeats to check the node state and the connectivity between nodes. When several heartbeats to the node are lost in a row, this node is kicked out of the cluster to allow writes to the remaining alive nodes. You can configure the heartbeat frequency and the response timeout in the multimaster.heartbeat_send_timeout and multimaster.heartbeat_recv_timeout parameters, respectively.

For example, suppose a five-node multi-master cluster experienced a network failure that split the network into two isolated subnets, with two and three cluster nodes. Based on heartbeats propagation information, multimaster will continue accepting writes at each node in the bigger partition, and deny all writes in the smaller one. Thus, a cluster consisting of $2N+1$ nodes can tolerate N node failures and stay alive if any $N+1$ nodes are alive and connected to each other. You can also set up a two nodes cluster plus a lightweight referee node that does not hold the data, but acts as a tie-breaker during symmetric node partitioning. For details, see Section F.37.3.3.

In case of a partial network split when different nodes have different connectivity, multimaster finds a fully connected subset of nodes and disconnects nodes outside of this subset. For example, in a three-node cluster, if node A can access both B and C, but node B cannot access node C, multimaster isolates node C to ensure that both A and B can work.

To preserve order of transactions on different nodes and thus data integrity, the decision to exclude or add back node(s) must be taken coherently. Generations which represent a subset of currently supposedly live nodes serve this purpose. Technically, generation is a pair <n, members> where *n* is unique number and *members* is subset of configured nodes. A node always lives in some generation and switches to the one with higher number as soon as it learns about its existence; generation numbers act as logical clocks/terms/epochs here. Each transaction is stamped during commit with current generation of the node it is being executed on. The transaction can be proposed to be committed only after it has been

PREPAREd on all its generation members. This allows to design the recovery protocol so that order of conflicting committed transactions is the same on all nodes. Node resides in generation in one of three states (can be shown with `mtm.status()`):

1. `ONLINE`: node is member of the generation and making transactions normally;
2. `RECOVERY`: node is member of the generation, but it must apply in recovery mode transactions from previous generations to become `ONLINE`;
3. `DEAD`: node will never be `ONLINE` in this generation;

For alive nodes, there is no way to distinguish between a failed node that stopped serving requests and a network-partitioned node that can be accessed by database users, but is unreachable for other nodes. If during commit of writing transaction some of current generation members are disconnected, transaction is rolled back according to generation rules. To avoid futile work, connectivity is also checked during transaction start; if you try to access an isolated node, `multimaster` returns an error message indicating the current status of the node. Thus, to prevent stale reads read-only queries are also forbidden. If you would like to continue using a disconnected node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension on this node, as explained in Section F.37.4.5.

Each node maintains a data structure that keeps the information about the state of all nodes in relation to this node. You can get this data by calling the `mtm.status()` and the `mtm.nodes()` functions.

When a failed node connects back to the cluster, `multimaster` starts automatic recovery:

1. The reconnected node selects a cluster node, which is `ONLINE` in the highest generation, referred to as the *donor* node, and starts catching up with the current state of the cluster based on the Write-Ahead Log (WAL).
2. When the node is caught up, it ballots for including itself in the next generation. Once generation is elected, commit of new transactions will start waiting for apply on the joining node.
3. When the rest of transactions till the switch to the new generation is applied, the reconnected node is promoted to the `online` state and included into the replication scheme.

The correctness of recovery protocol was verified with TLA+ model checker. You can find the model (and more detailed description) at *doc/specs* directory of the source code.

Automatic recovery requires presence of all WAL files generated after node failure. If a node is down for a long time and storing more WALs is unacceptable, you may have to exclude this node from the cluster and manually restore it from one of the working nodes using pg_basebackup. For details, see Section F.37.4.3.

F.37.2.3. Multimaster Background Workers

mtm-monitor

Starts all other workers for a database managed with multimaster. This is the first worker loaded during multimaster boot. Each multimaster node has a single `mtm-monitor` worker. When a new node is added, `mtm-monitor` starts `mtm-logrep-receiver` and `mtm-dmq-receiver` workers to enable replication to this node. If a node is dropped, `mtm-monitor` stops `mtm-logrep-receiver` and `mtm-dmq-receiver` workers that have been serving the dropped node. Each `mtm-monitor` controls workers on its own node only.

mtm-logrep-receiver

Receives logical replication stream from a given peer node. During normal operation, `mtm-logrep-receiver` sends replicated transactions to the pool of dynamic workers (see mtm-logrep-receiver-dynworker). During catchup, depending on the value of the multimaster.catchup_algorithm configuration parameter, `mtm-logrep-receiver` applies replicated transactions on the reconnected node or sends them to the pool of dynamic workers. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

mtm-dmq-receiver

Receives acknowledgment for transactions sent to peers and checks for heartbeat timeouts. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

mtm-dmq-sender

Collects acknowledgment for transactions applied on the current node and sends them to the corresponding mtm-dmq-receiver on the peer node. There is a single worker per Postgres Pro Enterprise instance.

mtm-logrep-receiver-dynworker

Dynamic pool worker for a given mtm-logrep-receiver. Applies replicated transactions received during normal operation or catchup. You can use the multimaster.max_workers configuration parameter to specify the maximum number of dynamic workers.

mtm-resolver

Performs Paxos to resolve unfinished transactions. This worker is only active during recovery or when connection with other nodes was lost. There is a single worker per Postgres Pro Enterprise instance.

mtm-campaigner

Ballots for new generations to exclude some node(s) or add myself. There is a single worker per Postgres Pro Enterprise instance.

mtm-replier

Responds to requests of mtm-campaigner and mtm-resolver.

F.37.3. Installation and Setup

To use `multimaster`, you need to install Postgres Pro or Postgres Pro Enterprise on all nodes of your cluster. Postgres Pro includes all the required dependencies and extensions. For PostgreSQL follow build and install instructions at *readme.md*.

F.37.3.1. Setting up a Multi-Master Cluster

Suppose you are setting up a cluster of three nodes, with `node1`, `node2`, and `node3` host names. After installing Postgres Pro Enterprise on all nodes, you need to initialize data directory on each node, as explained in Section 18.2. If you would like to set up a multi-master cluster for an already existing `mydb` database, you can load data from `mydb` to one of the nodes once the cluster is initialized, or you can load data to all new nodes before cluster initialization using any convenient mechanism, such as pg_basebackup or pg_dump.

Once the data directory is set up, complete the following steps on each cluster node:

1. Modify the `postgresql.conf` configuration file, as follows:

   - Add `multimaster` to the `shared_preload_libraries` variable:

     ```
     shared_preload_libraries = 'multimaster'
     ```

> **Tip**
>
> If the `shared_preload_libraries` variable is already defined in `postgresql.auto.conf`, you will need to modify its value using the ALTER SYSTEM command. For details, see Section 19.1.2. Note that in a multi-master cluster, the `ALTER SYSTEM` command only affects the configuration of the node from which it was run.

- Set up Postgres Pro Enterprise parameters related to replication:

  ```
  wal_level = logical
  max_connections = 100
  max_prepared_transactions = 300 # max_connections * N
  max_wal_senders = 10            # at least N
  max_replication_slots = 10      # at least 2N
  wal_sender_timeout = 0
  ```

  where *N* is the number of nodes in your cluster.

  You must change the replication level to `logical` as `multimaster` relies on logical replication. For a cluster of *N* nodes, enable at least *N* WAL sender processes and replication slots. Since `multimaster` implicitly adds a `PREPARE` phase to each `COMMIT` transaction, make sure to set the number of prepared transactions to *N* * `max_connections`. `wal_sender_timeout` should be disabled as multimaster uses its custom logic for failure detection.

- Make sure you have enough background workers allocated for each node:

  ```
  max_worker_processes = 250 # (N - 1) * (multimaster.max_workers + 1) + 5
  ```

  For example, for a three-node cluster with `multimaster.max_workers` = 100, `multimaster` may need up to 207 background workers at peak times: five always-on workers (monitor, resolver, dmq-sender, campaigner, replier), one walreceiver per each peer node and up to 200 replication dynamic workers. When setting this parameter, remember that other modules may also use background workers at the same time.

- Depending on your network environment and usage patterns, you may want to tune other `multimaster` parameters. For details, see Section F.37.3.2.

2. Start Postgres Pro Enterprise on all nodes.
3. Create database `mydb` and user `mtmuser` on each node:

   ```
   CREATE USER mtmuser WITH SUPERUSER PASSWORD 'mtmuserpassword';
   CREATE DATABASE mydb OWNER mtmuser;
   ```

   If you are using password-based authentication, you may want to create a password file.

   You can omit this step if you already have a database you are going to replicate, but you are recommended to create a separate superuser for multi-master replication. The examples below assume that you are going to replicate the `mydb` database on behalf of `mtmuser`.

4. Allow replication of the `mydb` database to each cluster node on behalf of `mtmuser`, as explained in Section 20.1. Make sure to use the authentication method that satisfies your security requirements. For example, `pg_hba.conf` might have the following lines on `node1`:

   ```
   host replication mtmuser node2 md5
   host mydb mtmuser node2 md5
   host replication mtmuser node3 md5
   host mydb mtmuser node3 md5
   ```

5. Connect to any node on behalf of the `mtmuser` database user, create the `multimaster` extension in the `mydb` database and run `mtm.init_cluster()`, specifying the connection string to the current node as the first argument and an array of connection strings to the other nodes as the second argument.

   For example, if you would like to connect to `node1`, run:

   ```
   CREATE EXTENSION multimaster;
   SELECT mtm.init_cluster('dbname=mydb user=mtmuser host=node1',
   '{"dbname=mydb user=mtmuser host=node2", "dbname=mydb user=mtmuser host=node3"}');
   ```

6. To ensure that `multimaster` is enabled, you can run the `mtm.status()` and `mtm.nodes()` functions:

   ```
   SELECT * FROM mtm.status();
   ```

```
SELECT * FROM mtm.nodes();
```

If `status` is equal to `online` and all nodes are present in the `mtm.nodes` output, your cluster is successfully configured and ready to use.

> **Tip**
>
> If you have any data that must be present on one of the nodes only, you can exclude a particular table from replication, as follows:
>
> ```
> SELECT mtm.make_table_local('table_name')
> ```

F.37.3.2. Tuning Configuration Parameters

While you can use `multimaster` in the default configuration, you may want to tune several parameters for faster failure detection or more reliable automatic recovery.

F.37.3.2.1. Setting Timeout for Failure Detection

To check availability of the peer nodes, `multimaster` periodically sends heartbeat packets to all nodes. You can define the timeout for failure detection with the following variables:

- The `multimaster.heartbeat_send_timeout` variable defines the time interval between the heartbeats. By default, this variable is set to 200ms.
- The `multimaster.heartbeat_recv_timeout` variable sets the timeout for the response. If no heartbeats are received during this time, the node is assumed to be disconnected and is excluded from the cluster. By default, this variable is set to 2000ms.

It's a good idea to set `multimaster.heartbeat_send_timeout` based on typical ping latencies between the nodes. Small recv/send ratio decreases the time of failure detection, but increases the probability of false-positive failure detection. When setting this parameter, take into account the typical packet loss ratio between your cluster nodes.

F.37.3.3. 2+1 Mode: Setting up a Standalone Referee Node

By default, `multimaster` uses a majority-based algorithm to determine whether the cluster nodes have a quorum: a cluster can only continue working if the majority of its nodes are alive and can access each other. Majority-based approach is pointless for two nodes cluster: if one of them fails, another one becomes inaccessible. There is a special 2+1 or referee mode which trades less hardware resources by decreasing availability: two nodes hold full copy of data, and separate referee node participates only in voting, acting as a tie-breaker.

If one node goes down, another one requests referee grant (elects referee-approved generation with single node). Once the grant is received, it continues to work normally. If offline node gets up, it recovers and elects full generation containing both nodes, essentially removing the grant - this allows the node to get it in its turn later. While the grant is issued, it can't be given to another node until full generation is elected and excluded node recovers. This ensures data loss doesn't happen by the price of availability: in this setup two nodes (one normal and one referee) can be alive but cluster might be still unavailable if the referee winner is down, which is impossible with classic three nodes configuration.

The referee node does not store any cluster data, so it is not resource-intensive and can be configured on virtually any system with Postgres Pro Enterprise installed.

To avoid split-brain problems, you must have only a single referee in your cluster.

To set up a referee for your cluster:

1. Install Postgres Pro Enterprise on the node you are going to make a referee and create the `referee` extension:

   ```
   CREATE EXTENSION referee;
   ```

2. Make sure the `pg_hba.conf` file allows access to the referee node.
3. Set up the nodes that will hold cluster data following the instructions in Section F.37.3.1.
4. On all data nodes, specify the referee connection string in the `postgresql.conf` file:

   ```
   multimaster.referee_connstring = connstring
   ```

   where *`connstring`* holds libpq options required to access the referee.

The first subset of nodes that gets connected to the referee wins the voting and starts working. The other nodes have to go through the recovery process to catch up with them and join the cluster. Under heavy load, the recovery can take unpredictably long, so it is recommended to wait for all data nodes going online before switching on the load when setting up a new cluster. Once all the nodes get online, the referee discards the voting result, and all data nodes start operating together.

In case of any failure, the voting mechanism is triggered again. At this time, all nodes appear to be offline for a short period of time to allow the referee to choose a new winner, so you can see the following error message when trying to access the cluster: `[multimaster] node is not online: current status is "disabled"`.

F.37.4. Multi-Master Cluster Administration

- Monitoring the Cluster Status
- Accessing Disabled Nodes
- Adding New Nodes to the Cluster
- Removing Nodes from the Cluster
- Checking Data Consistency Across Cluster Nodes
- Delayed Transaction Commits

F.37.4.1. Monitoring Cluster Status

`multimaster` provides several functions to check the current cluster state.

To check node-specific information, use `mtm.status()`:

```
SELECT * FROM mtm.status();
```

To get the list of all nodes in the cluster together with their status, use `mtm.nodes()`:

```
SELECT * FROM mtm.nodes();
```

For details on all the returned information, see Section F.37.5.2.

F.37.4.2. Accessing Disabled Nodes

If a cluster node is disabled, any attempt to read or write data on this node raises an error by default. If you need to access the data on a disabled node, you can override this behavior at connection time by setting the application_name parameter to `mtm_admin`. In this case, you can run read and write queries on this node without multimaster supervision.

F.37.4.3. Adding New Nodes to the Cluster

> **Note**
>
> You must add nodes one by one. Avoid adding several nodes in parallel as this could cause errors.

With the `multimaster` extension, you can add or drop cluster nodes. Before adding node, stop the load and ensure (with `mtm.status()`) that all nodes are `online`. When adding a new node, you need to load all the data to this node using pg_basebackup from any cluster node, and then start this node.

Suppose we have a working cluster of three nodes, with `node1`, `node2`, and `node3` host names. To add `node4`, follow these steps:

1. Figure out the required connection string to access the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string can be `"dbname=mydb user=mtmuser host=node4"`.
2. In `psql` connected to any alive node, run:

   ```
   SELECT mtm.add_node('dbname=mydb user=mtmuser host=node4');
   ```

   This command changes the cluster configuration on all nodes and creates replication slots for the new node. It also returns `node_id` of the new node, which will be required to complete the setup.
3. Go to the new node and clone all the data from one of the alive nodes to this node:

   ```
   pg_basebackup -D datadir -h node1 -U mtmuser -c fast -v
   ```

   pg_basebackup copies the entire data directory from `node1`, together with configuration settings, and prints the last LSN replayed from WAL, such as `'0/12D357F0'`. This value will be required to complete the setup.
4. Configure the new node to boot with `recovery_target=immediate` to prevent redo past the point where replication will begin. Add to `postgresql.conf`:

   ```
   restore_command = 'false'
   recovery_target = 'immediate'
   recovery_target_action = 'promote'
   ```

   And create `recovery.signal` file in the data directory.
5. Start Postgres Pro Enterprise on the new node.
6. In `psql` connected to the node used to take the base backup, run:

   ```
   SELECT mtm.join_node(4, '0/12D357F0');
   ```

   where `4` is the `node_id` returned by the `mtm.add_node()` function call and `'0/12D357F0'` is the LSN value returned by pg_basebackup.

F.37.4.4. Removing Nodes from the Cluster

Before removing node, stop the load and ensure (with `mtm.status()`) that all nodes (except the ones to be dropped) are `online`. Shut down the nodes you are going to remove. To remove the node from the cluster:

1. Run the `mtm.nodes()` function to learn the ID of the node to be removed:

   ```
   SELECT * FROM mtm.nodes();
   ```
2. Run the `mtm.drop_node()` function with this node ID as a parameter:

   ```
   SELECT mtm.drop_node(3);
   ```

   This will delete replication slots for node 3 on all cluster nodes and stop replication to this node.

If you would like to return the node to the cluster later, you will have to add it as a new node, as explained in Section F.37.4.3.

F.37.4.5. Uninstalling the multimaster Extension

If you would like to continue using the node that has been removed from the cluster in the standalone mode, you have to drop the `multimaster` extension on this node and clean up all `multimaster`-related subscriptions and uncommitted transactions to ensure that the node is no longer associated with the cluster.

1. Remove `multimaster` from shared_preload_libraries and restart Postgres Pro Enterprise.

2. Delete the `multimaster` extension and publication:

```
DROP EXTENSION multimaster;
DROP PUBLICATION multimaster;
```

3. Review the list of existing subscriptions using the `\dRs` command and delete each subscription that starts with the `mtm_sub_` prefix:

```
\dRs
DROP SUBSCRIPTION mtm_sub_subscription_name;
```

4. Review the list of existing replication slots and delete each slot that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_slots;
SELECT pg_drop_replication_slot('mtm_slot_name');
```

5. Review the list of existing replication origins and delete each origin that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_origin;
SELECT pg_replication_origin_drop('mtm_origin_name');
```

6. Review the list of prepared transaction left, if any:

```
SELECT * FROM pg_prepared_xacts;
```

   You have to commit or abort these transactions by running `ABORT PREPARED transaction_id` or `COMMIT PREPARED transaction_id`, respectively.

Once all these steps are complete, you can start using the node in the standalone mode, if required.

F.37.4.6. Checking Data Consistency Across Cluster Nodes

You can check that the data is the same on all cluster nodes using the mtm.check_query(query_text) function.

As a parameter, this function takes the text of a query you would like to run for data comparison. When you call this function, it takes a consistent snapshot of data on each cluster node and runs this query against the captured snapshots. The query results are compared between pairs of nodes. If there are no differences, this function returns `true`. Otherwise, it reports the first detected difference in a warning and returns `false`.

To avoid false-positive results, always use the `ORDER BY` clause in your test query. For example, suppose you would like to check that the data in a `my_table` is the same on all cluster nodes. Compare the results of the following queries:

```
postgres=# SELECT mtm.check_query('SELECT * FROM my_table ORDER BY id');
 check_query
-------------
 t
(1 row)

postgres=# SELECT mtm.check_query('SELECT * FROM my_table');
WARNING: mismatch in column 'b' of row 0: 256 on node0, 255 on node1
 check_query
-------------
 f
(1 row)
```

Even though the data is the same, the second query reports an issue because the order of the returned data differs between cluster nodes.

F.37.4.7. Delayed Transaction Commits

When a lagging node is catching up to the donor node and cannot apply changes as quickly, you can slow down transaction execution on the donor node using the `multimaster.tx_delay_on_slow_catchup` configuration parameter. To do this, set this parameter to `on` in the `postgresql.conf` configuration file

on the donor node, but not on the lagging peer node. If you edit the file on a running server, you will need to signal the postmaster to make it re-read the file (see Chapter 19 for details). If necessary, you can also specify the maximum possible delay for transaction execution in the optional `multimaster.max_tx_delay_on_slow_catchup` parameter (in milliseconds). A value of `0` means that no maximum delay is set. Currently, delays can range from 1 ms to approximately 4 seconds. Values outside the allowed range will be truncated towards the nearest valid value.

By default, this feature is disabled.

F.37.5. Reference

F.37.5.1. Configuration Parameters

`multimaster.heartbeat_recv_timeout`

Timeout, in milliseconds. If no heartbeat message is received from the node within this timeframe, the node is excluded from the cluster.

Default: 2000 ms

`multimaster.heartbeat_send_timeout`

Time interval between heartbeat messages, in milliseconds. An arbiter process broadcasts heartbeat messages to all nodes to detect connection problems.

Default: 200 ms

`multimaster.max_workers`

The maximum number of `walreceiver` workers per peer node.

> **Important**
>
> This parameter should be used with caution. If the number of simultaneous transactions in the whole cluster is bigger than the provided value, it can lead to undetected deadlocks.

Default: 100

`multimaster.monotonic_sequences`

Defines the sequence generation mode for unique identifiers. This variable can take the following values:

- `false` (default) — ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly.
- `true` — the generated sequence increases monotonically cluster-wide. ID generation on each node is started with this node number and is incremented by the number of nodes, but the values are omitted if they are smaller than the already generated IDs on another node. For example, in a three-node cluster, if 1, 4 and 7 IDs are already allocated to the objects on the first node, 2 and 5 IDs will be omitted on the second node. In this case, the first ID on the second node is 8. Thus, the next generated ID is always higher than the previous one, regardless of the cluster node.

Default: `false`

`multimaster.referee_connstring`

Connection string to access the referee node. You must set this parameter on all cluster nodes if the referee is set up.

`multimaster.remote_functions`

Provides a comma-separated list of function names that should be executed remotely on all multimaster nodes instead of replicating the result of their work.

`multimaster.trans_spill_threshold`

The maximal size of transaction, in kB. When this threshold is reached, the transaction is written to the disk.

Default: 100MB

`multimaster.break_connection`

Break connection with clients connected to the node if this node disconnects from the cluster. If this variable is set to `false`, the client stays connected to the node but receives an error that the node is disabled.

Default: `false`

`multimaster.connect_timeout`

Maximum time to wait while connecting, in seconds. Zero, negative, or not specified means wait indefinitely. The minimum allowed timeout is 2 seconds, therefore a value of `1` is interpreted as `2`.

Default: `0`

`multimaster.ignore_tables_without_pk`

Do not replicate tables without primary key. When `false`, such tables are replicated.

Default: `false`

`multimaster.syncpoint_interval`

Amount of WAL generated between synchronization points.

Default: `10 MB`

`multimaster.binary_basetypes`

Send data of built-in types in binary format.

Default: `true`

`multimaster.wait_peer_commits`

Wait until all peers commit the transaction before the command returns a success indication to the client.

Default: `true`

`multimaster.deadlock_prevention`

Manage prevention of transaction deadlocks that can occur when the same tuple is updated or deleted on different nodes simultaneously. If set to `off`, deadlock prevention is disabled.

If set to `simple`, the conflicting transactions are rejected. This setting may be used in any setup.

If set to `smart`, a specific algorithm is used to provide best resource availability by selectively committing or rejecting transactions. This is recommended for a setup of two nodes and a referee. In three node setups, deadlocks are still possible. If there are more than four nodes, all conflicting transactions are rejected, just as with `simple`.

Default: `off`

`multimaster.tx_delay_on_slow_catchup`

Enable delay of transaction commits on the donor node when peer nodes are catching up to this node. This parameter should only be set on the donor node.

Default: `off`

`multimaster.max_tx_delay_on_slow_catchup`

If `multimaster.tx_delay_on_slow_catchup` is enabled, this parameter specifies maximum transaction execution delay, in milliseconds. Possible values are integers greater than `0`, but it allows values only up to 4 seconds.

Default: 0

`multimaster.enable_async_3pc_on_catchup`

Enables asynchronous commit operations (`PREPARE`, `PRECOMMIT`, and `COMMIT PREPARED`) on a lagging node syncing with the donor node. This significantly accelerates the catchup process. Data integrity is maintained using the synchronization point mechanism: during catchup, the system periodically creates synchronization points when all preceding transactions are safely written to disk. This way, even if the lagging node is restarted, no transaction data is lost.

Default: true

`multimaster.catchup_algorithm`

Catchup mode for reconnected nodes. It determines how replicated transactions are applied on the reconnected node that is catching up. This configuration parameter can take one of the following values:

- `sequential` — `mtm-logrep-receiver` applies replicated transactions sequentially in the order they are received.
- `parallel` — `mtm-logrep-receiver` sends replicated transactions to the pool of dynamic workers (see mtm-logrep-receiver-dynworker). Dynamic workers apply non-conflicting transactions in parallel and conflicting transactions sequentially in the receiving order, similar to the `sequential` catchup mode. You can use the multimaster.parallel_catchup_workers configuration parameter to specify the maximum number of dynamic workers that can apply replicated transactions in this catchup mode.

Default: `sequential`

`multimaster.parallel_catchup_workers`

The maximum number of dynamic workers that can apply replicated transactions on the reconnected node in the `parallel` catchup mode. The value of this configuration parameter cannot be greater than that of the multimaster.max_workers configuration parameter. You can use the multimaster.catchup_algorithm configuration parameter to specify the catchup mode for reconnected nodes.

Default: `8`

F.37.5.2. Functions

`mtm.init_cluster(`*`my_conninfo`* `text, `*`peers_conninfo`* `text[])`

Initializes cluster configuration on all nodes. It connects the current node to all nodes listed in *`peers_conninfo`* and creates the multimaster extension, replications slots, and replication origins on each node. Run this function once all the nodes are running and can accept connections.

Arguments:

- *`my_conninfo`* — connection string to the node on which you are running this function. Peer nodes use this string to connect back to this node.

- *peers_conninfo* — an array of connection strings to all the other nodes to be added to the cluster.

`mtm.add_node(connstr text)`

Adds a new node to the cluster. This function should be called before loading data to this node using pg_basebackup. `mtm.add_node` creates the required replication slots for a new node, so you can add a node while the cluster is under load.

Arguments:

- *connstr* — connection string for the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string is `"dbname=mydb user=mtmuser host=node4"`.

`mtm.join_node(node_id int, backup_end_lsn pg_lsn)`

Completes the cluster setup after adding a new node. This function should be called after the added node has been started.

Arguments:

- *node_id* — ID of the node to add to the cluster. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

  backup_end_lsn — the last LSN of the base backup copied to the new node. This LSN will be used as the starting point for data replication once the node joins the cluster.

`mtm.drop_node(node_id integer)`

Excludes a node from the cluster.

If you would like to continue using this node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension from this node, as explained in Section F.37.4.5.

Arguments:

- *node_id* — ID of the node being dropped. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

`mtm.alter_sequences()`

Fixes unique identifiers on all cluster nodes. This may be required after restoring all nodes from a single base backup.

`mtm.status()`

Shows the status of the `multimaster` extension on the current node. Returns a tuple of the following values:

- *my_node_id*, `int` — ID of this node.
- *status*, `text` — status of the node. Possible values are: `online`, `recovery`, `catchup`, `disabled` (need to recover, but not yet clear from whom), `isolated` (online in current generation, but some members are disconnected).
- *connected*, `int[]` — array of peer IDs connected to this node.
- *gen_num*, `int8` — current generation number.
- *gen_members*, `int[]` — array of current generation members node IDs.

- *gen_members_online*, int[] — array of current generation members node IDs which are online in it.
- *gen_configured*, int[] — array of node IDs configured in current generation.

mtm.nodes()

Shows the information on all nodes in the cluster. Returns a tuple of the following values:

- *id*, integer — node ID.
- *conninfo*, text — connection string to this node.
- *is_self*, boolean — is it me?
- *enabled*, boolean — is this node online in current generation?
- *connected*, boolean — shows whether the node is connected to our node.
- *sender_pid*, integer — WAL sender process ID.
- *receiver_pid*, integer — WAL receiver process ID.
- *n_workers*, text — number of started dynamic apply workers from this node.
- *receiver_mode*, text — in which mode receiver from this node works. Possible values are: disabled, recovery, normal.

mtm.make_table_local(*relation* regclass)

Stops replication for the specified table.

Arguments:

- *relation* — the table you would like to exclude from the replication scheme.

mtm.check_query(*query_text* text)

Checks data consistency across cluster nodes. This function takes a snapshot of the current state of each node, runs the specified query against these snapshots, and compares the results. If the results are different between any two nodes, displays a warning with the first found issue and returns false. Otherwise, returns true.

Arguments:

- *query_text* — the query you would like to run on all nodes for data comparison. To avoid false-positive results, always use the ORDER BY clause in the test query.

mtm.get_snapshots()

Takes a snapshot of data on each cluster node and returns the snapshot ID. The snapshots remain available until the mtm.free_snapshots() is called, or the current session is terminated. This function is used by the mtm.check_query(query_text), there is no need to call it manually.

mtm.free_snapshots()

Removes data snapshots taken by the mtm.get_snapshots() function. This function is used by the mtm.check_query(query_text), there is no need to call it manually.

F.37.6. Compatibility

F.37.6.1. Local and Global DDL Statements

By default, any DDL statement is executed on all cluster nodes, except the following statements that can only act locally on a given node:

- ALTER SYSTEM

- CREATE DATABASE
- DROP DATABASE
- REINDEX
- CHECKPOINT
- CLUSTER
- LOAD
- LISTEN
- CHECKPOINT
- NOTIFY

F.37.7. Authors

Postgres Professional, Moscow, Russia.

F.37.7.1. Credits

The replication mechanism is based on logical decoding and an earlier version of the pglogical extension provided for community by the 2ndQuadrant team.

The Paxos consensus algorithm is described at:

- Leslie Lamport. *The Part-Time Parliament*

Parallel replication and recovery mechanism is similar to the one described in:

- Odorico M. Mendizabal, et al. *Checkpointing in Parallel State-Machine Replication*.

F.38. online_analyze — update statistics after INSERT, UPDATE, DELETE, or SELECT INTO operations

The online_analyze module provides a set of features that immediately update statistics after INSERT, UPDATE, DELETE, or SELECT INTO operations for the affected tables.

> **Note**
>
> This extension cannot be used together with autonomous transactions or while built-in connection pooling is enabled.

F.38.1. Module Loading

To use online_analyze module, load the shared library:

```
LOAD 'online_analyze';
```

F.38.2. Module Configuration

You can configure online_analyze using the following custom variables (default values are shown):

- online_analyze.enable = on

  Enables online_analyze.

- online_analyze.verbose = on

  Executes ANALYZE VERBOSE.

  > **Note**
  >
  > Since verbose is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:
  >
  > ```
  > ALTER SYSTEM SET "online_analyze.verbose" = 'off';
  > ```

- online_analyze.scale_factor = 0.1

  Fraction of table size to start online analysis (similar to autovacuum_analyze_scale_factor).

- online_analyze.threshold = 50

  Minimum number of row updates before starting online analysis (similar to autovacuum_analyze_threshold).

- online_analyze.min_interval = 10000

  Minimum time interval between ANALYZE calls per table, in milliseconds.

- online_analyze.table_type = "all"

  Type(s) of tables for online analysis. Possible values are: all, persistent, temporary, none.

- online_analyze.exclude_tables = ""

  List of tables to exclude from online analysis.

- online_analyze.include_tables = ""

  List of tables to include in online analysis (online_analyze.include_tables overrides online_analyze.exclude_tables).

- online_analyze.local_tracking = off

  Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- online_analyze.lower_limit = 0

  Minimum number of rows in a table required to trigger `online_analyze`.

- online_analyze.capacity_threshold = 100000

  Maximum number of temporary tables to store in local cache.

F.38.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.39. old_snapshot — inspect old_snapshot_threshold state

The old_snapshot module allows inspection of the server state that is used to implement old_snapshot_threshold.

F.39.1. Functions

pg_old_snapshot_time_mapping(array_offset OUT int4, end_timestamp OUT timestamptz, newest_xmin OUT xid) returns setof record

Returns all of the entries in the server's timestamp to XID mapping. Each entry represents the newest xmin of any snapshot taken in the corresponding minute.

F.40. pageinspect — low-level inspection of database pages

The pageinspect module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.40.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint) returns bytea`

get_raw_page reads the specified block of the named relation and returns a copy as a bytea value. This allows a single time-consistent copy of the block to be obtained. *fork* should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno bigint) returns bytea`

A shorthand version of get_raw_page, for reading from the main fork. Equivalent to get_raw_page(relname, 'main', blkno)

`page_header(page bytea) returns record`

page_header shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with get_raw_page should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
    lsn    | checksum | flags  | lower | upper | special | pagesize | version |
 xid_base | multi_base | prune_xid
-----------+----------+--------+-------+-------+---------+----------+---------
+----------+------------+----------
 0/24A1B50 |        0 |      1 |   232 |   368 |    8192 |     8192 |       4 |
   0 |          0 |        0
```

The returned columns correspond to the fields in the PageHeaderData struct.

The checksum field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno bigint) returns smallint`

page_checksum computes the checksum for the page, as if it was located at the given block.

A page image obtained with get_raw_page should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
---------------
         13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the checksum result field of the function page_header. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea) returns text`

fsm_page_contents shows the internal node structure of an FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

F.40.2. Heap Functions

`heap_page_items(page bytea) returns setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool]) returns bytea[]`

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
 t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If *`do_detoast`* is `true`, attributes will be detoasted as needed. Default value is `false`.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool]) returns setof record`

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by *`do_detoast`* which is `false` by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
 'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer) returns record`

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
         FROM heap_page_items(get_raw_page('pg_class', 0)),
           LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
         WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

F.40.3. B-Tree Functions

`bt_metap(relname text) returns record`

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-------------+-------
magic                     | 340322
version                   | 4
root                      | 1
level                     | 0
fastroot                  | 1
fastlevel                 | 0
last_cleanup_num_delpages | 0
last_cleanup_num_tuples   | 230
allequalimage             | f
```

`bt_page_stats(relname text, blkno bigint) returns record`

`bt_page_stats` returns summary information about a data page of a B-tree index. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno         | 1
type          | l
live_items    | 224
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 3668
btpo_prev     | 0
btpo_next     | 0
btpo_level    | 0
btpo_flags    | 3
```

`bt_multi_page_stats(relname text, blkno bigint, blk_count bigint) returns setof record`

`bt_multi_page_stats` returns the same information as `bt_page_stats`, but does so for each page of the range of pages beginning at *`blkno`* and extending for *`blk_count`* pages. If *`blk_count`* is negative, all pages from *`blkno`* to the end of the index are reported on. For example:

```
test=# SELECT * FROM bt_multi_page_stats('pg_proc_oid_index', 5, 2);
-[ RECORD 1 ]-+-----
blkno         | 5
type          | l
live_items    | 367
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 808
btpo_prev     | 4
btpo_next     | 6
btpo_level    | 0
btpo_flags    | 1
-[ RECORD 2 ]-+-----
blkno         | 6
type          | l
live_items    | 367
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 808
btpo_prev     | 5
btpo_next     | 7
btpo_level    | 0
```

```
 btpo_flags    | 1
```

```
bt_page_items(relname text, blkno bigint) returns setof record
```

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
 some_tids
       FROM bt_page_items('tenk2_hundred', 5);
 itemoffset |   ctid    | itemlen | nulls | vars |          data           | dead |
 htid  |      some_tids
------------+-----------+---------+-------+------+-------------------------+------
+--------+--------------------
           1 | (16,1)    |      16 | f     | f    | 30 00 00 00 00 00 00 00 |      |
       |
           2 | (16,8292) |     616 | f     | f    | 24 00 00 00 00 00 00 00 | f    |
 (1,6)  | {"(1,6)","(10,22)"}
           3 | (16,8292) |     616 | f     | f    | 25 00 00 00 00 00 00 00 | f    |
 (1,18) | {"(1,18)","(4,22)"}
           4 | (16,8292) |     616 | f     | f    | 26 00 00 00 00 00 00 00 | f    |
 (4,18) | {"(4,18)","(6,17)"}
           5 | (16,8292) |     616 | f     | f    | 27 00 00 00 00 00 00 00 | f    |

(13 rows)
```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset` number 1. `ctid` is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page's “high key”, meaning its `data` serves as an upper bound on all items appearing on

the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see Section 68.4.1. For more details about deduplication and posting lists, see Section 68.4.3.

`bt_page_items(page bytea) returns setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
 some_tids
        FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset |   ctid    | itemlen | nulls | vars |          data           | dead |
 htid  |      some_tids
------------+-----------+---------+-------+------+-------------------------+------
+--------+--------------------
           1 | (16,1)    |      16 | f     | f    | 30 00 00 00 00 00 00 00 |      |
       |
           2 | (16,8292) |     616 | f     | f    | 24 00 00 00 00 00 00 00 | f    |
 (1,6)  | {"(1,6)","(10,22)"}
           3 | (16,8292) |     616 | f     | f    | 25 00 00 00 00 00 00 00 | f    |
 (1,18) | {"(1,18)","(4,22)"}
           4 | (16,8292) |     616 | f     | f    | 26 00 00 00 00 00 00 00 | f    |
 (4,18) | {"(4,18)","(6,17)"}
           5 | (16,8292) |     616 | f     | f    | 27 00 00 00 00 00 00 00 | f    |
 (1,2)  | {"(1,2)","(1,19)"}
           6 | (16,8292) |     616 | f     | f    | 28 00 00 00 00 00 00 00 | f    |

           7 | (16,8292) |     616 | f     | f    | 29 00 00 00 00 00 00 00 | f    |
 (2,17) | {"(2,17)","(11,2)"}
           8 | (16,8292) |     616 | f     | f    | 2a 00 00 00 00 00 00 00 | f    |
 (0,25) | {"(0,25)","(3,20)"}
           9 | (16,8292) |     616 | f     | f    | 2b 00 00 00 00 00 00 00 | f    |
 (0,10) | {"(0,10)","(0,14)"}
          10 | (16,8292) |     616 | f     | f    | 2c 00 00 00 00 00 00 00 | f    |
 (1,3)  | {"(1,3)","(3,9)"}
          11 | (16,8292) |     616 | f     | f    | 2d 00 00 00 00 00 00 00 | f    |
 (6,28) | {"(6,28)","(11,1)"}
          12 | (16,8292) |     616 | f     | f    | 2e 00 00 00 00 00 00 00 | f    |
 (0,27) | {"(0,27)","(1,13)"}
          13 | (16,8292) |     616 | f     | f    | 2f 00 00 00 00 00 00 00 | f    |
 (4,17) | {"(4,17)","(4,21)"}
(13 rows)
```

All the other details are the same as explained in the previous item.

F.40.4. BRIN Functions

`brin_page_type(page bytea) returns text`

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
 brin_page_type
----------------
 meta
```

```
brin_metapage_info(page bytea) returns record
```

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
   magic    | version | pagesperrange | lastrevmappage
------------+---------+---------------+---------------
 0xA8109CFA |       1 |             4 |              2
```

```
brin_revmap_data(page bytea) returns setof tid
```

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
  pages
---------
 (6,137)
 (6,138)
 (6,139)
 (6,140)
 (6,141)
```

```
brin_page_items(page bytea, index oid) returns setof record
```

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
       ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | empty |    value
------------+--------+--------+----------+----------+-------------+-------
+--------------
        137 |      0 |      1 | t        | f        | f           | f     |
        137 |      0 |      2 | f        | f        | f           | f     | {1 ..
 88}
        138 |      4 |      1 | t        | f        | f           | f     |
        138 |      4 |      2 | f        | f        | f           | f     | {89 ..
 176}
        139 |      8 |      1 | t        | f        | f           | f     |
        139 |      8 |      2 | f        | f        | f           | f     | {177 ..
 264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs.

F.40.5. GIN Functions

```
gin_metapage_info(page bytea) returns record
```

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]----+-----------
pending_head     | 4294967295
pending_tail     | 4294967295
tail_free_size   | 0
n_pending_pages  | 0
n_pending_tuples | 0
n_total_pages    | 7
n_entry_pages    | 6
n_data_pages     | 0
n_entries        | 693
version          | 2
```

```
gin_page_opaque_info(page bytea) returns record
```

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff |         flags
-----------+--------+-----------------------
         5 |      0 | {data,leaf,compressed}
(1 row)
```

```
gin_leafpage_items(page bytea) returns setof record
```

`gin_leafpage_items` returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
        FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes |                          some_tids
-----------+--------+-------------------------------------------------------------
 (8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
 (10,45)   |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
 (12,52)   |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
 (14,59)   |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
 (167,16)  |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
 (170,30)  |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
 (173,44)  |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

F.40.6. GiST Functions

```
gist_page_opaque_info(page bytea) returns record
```

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```
test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
 lsn | nsn | rightlink | flags
-----+-----+-----------+--------
 0/1 | 0/0 |         1 | {leaf}
(1 row)
```

```
gist_page_items(page bytea, index_oid regclass) returns setof record
```

`gist_page_items` returns information about the data stored in a page of a GiST index. For example:

```
test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0),
 'test_gist_idx');
 itemoffset |   ctid    | itemlen | dead |             keys
------------+-----------+---------+------+------------------------------
          1 | (1,65535) |      40 | f    | (p)=("(185,185),(1,1)")
          2 | (2,65535) |      40 | f    | (p)=("(370,370),(186,186)")
          3 | (3,65535) |      40 | f    | (p)=("(555,555),(371,371)")
          4 | (4,65535) |      40 | f    | (p)=("(740,740),(556,556)")
          5 | (5,65535) |      40 | f    | (p)=("(870,870),(741,741)")
          6 | (6,65535) |      40 | f    | (p)=("(1000,1000),(871,871)")
(6 rows)
```

```
gist_page_items_bytea(page bytea) returns setof record
```

Same as `gist_page_items`, but returns the key data as a raw `bytea` blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

```
test=# SELECT * FROM gist_page_items_bytea(get_raw_page('test_gist_idx', 0));
 itemoffset |   ctid    | itemlen | dead |
 key_data
```

```

(7 rows)
```

F.40.7. Hash Functions

`hash_page_type(page bytea) returns text`

`hash_page_type` returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
----------------
 metapage
```

`hash_page_stats(page bytea) returns setof record`

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]---+-----------
live_items      | 407
dead_items      | 0
page_size       | 8192
free_size       | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket    | 0
hasho_flag      | 66
hasho_page_id   | 65408
```

`hash_page_items(page bytea) returns setof record`

`hash_page_items` returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |   ctid    |    data
------------+-----------+------------
          1 | (899,77)  | 1053474816
          2 | (897,29)  | 1053474816
          3 | (894,207) | 1053474816
          4 | (892,159) | 1053474816
          5 | (890,111) | 1053474816
```

`hash_bitmap_info(index oid, blkno bigint) returns record`

`hash_bitmap_info` shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-------------+-----------+-----------
          65 |         3 | t
```

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#     maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test-#     regexp_replace(spares::text, '(,0)*}', '}') as spares,
test-#     regexp_replace(mapp::text, '(,0)*}', '}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD 1 ]-------------------------------------------------
magic     | 105121344
version   | 4
ntuples   | 500500
ffactor   | 40
bsize     | 8152
bmsize    | 4096
bmshift   | 15
maxbucket | 12512
highmask  | 16383
lowmask   | 8191
ovflpoint | 28
firstfree | 1204
nmaps     | 1
procid    | 450
spares    | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,
508,567,628,704,1193,1202,1204}
mapp      | {65}
```

F.41. passwordcheck — verify password strength

The passwordcheck module checks users' passwords whenever they are set with CREATE ROLE or ALTER ROLE (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '$libdir/passwordcheck' to shared_preload_libraries in postgresql.conf, then restart the server.

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the passwordcheck module, because in that case it can only try to guess the password. For this reason, passwordcheck is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 20) than to rely on passwords within the database.

F.42. pg_buffercache — inspect Postgres Pro buffer cache state

The pg_buffercache module provides a means for examining what's happening in the shared buffer cache in real time.

This module provides the pg_buffercache_pages() function (wrapped in the pg_buffercache view), the pg_buffercache_summary() function, and the pg_buffercache_usage_counts() function.

The pg_buffercache_pages() function returns a set of records, each row describing the state of one shared buffer entry. The pg_buffercache view wraps the function for convenient use.

The pg_buffercache_summary() function returns a single row summarizing the state of the shared buffer cache.

The pg_buffercache_usage_counts() function returns a set of records, each row describing the number of buffers with a given usage count.

By default, use is restricted to superusers and roles with privileges of the pg_monitor role. Access may be granted to others using GRANT.

F.42.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in Table F.23.

Table F.23. pg_buffercache Columns

Column Type Description
bufferid integer ID, in the range 1..shared_buffers
relfilenode oid (references pg_class .relfilenode) Filenode number of the relation
reltablespace oid (references pg_tablespace .oid) Tablespace OID of the relation
reldatabase oid (references pg_database .oid) Database OID of the relation
relforknumber smallint Fork number within the relation
relblocknumber bigint Page number within the relation
isdirty boolean Is the page dirty?
usagecount smallint Clock-sweep access count
pinning_backends integer Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except bufferid. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in pg_class for some rows, or that there could even be incorrect joins. If you are trying to join against pg_class, it's a good idea to restrict the join to rows having reldatabase equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing pg_buffercache view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

F.42.2. The pg_buffercache_summary() Function

The definitions of the columns exposed by the function are shown in Table F.24.

Table F.24. pg_buffercache_summary() Output Columns

Column Type Description
buffers_used int4 Number of used shared buffers
buffers_unused int4 Number of unused shared buffers
buffers_dirty int4 Number of dirty shared buffers
buffers_pinned int4 Number of pinned shared buffers
usagecount_avg float8 Average usage count of used shared buffers

The pg_buffercache_summary() function returns a single row summarizing the state of all shared buffers. Similar and more detailed information is provided by the pg_buffercache view, but pg_buffercache_summary() is significantly cheaper.

Like the pg_buffercache view, pg_buffercache_summary() does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.42.3. The pg_buffercache_usage_counts() Function

The definitions of the columns exposed by the function are shown in Table F.25.

Table F.25. pg_buffercache_usage_counts() Output Columns

Column Type Description
usage_count int4 A possible buffer usage count
buffers int4 Number of buffers with the usage count
dirty int4 Number of dirty buffers with the usage count
pinned int4 Number of pinned buffers with the usage count

The pg_buffercache_usage_counts() function returns a set of rows summarizing the states of all shared buffers, aggregated over the possible usage count values. Similar and more detailed information is provided by the pg_buffercache view, but pg_buffercache_usage_counts() is significantly cheaper.

Like the pg_buffercache view, pg_buffercache_usage_counts() does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.42.4. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
```

```
             FROM pg_buffercache b JOIN pg_class c
             ON b.relfilenode = pg_relation_filenode(c.oid) AND
                b.reldatabase IN (0, (SELECT oid FROM pg_database
                                      WHERE datname = current_database()))
             JOIN pg_namespace n ON n.oid = c.relnamespace
             GROUP BY n.nspname, c.relname
             ORDER BY 3 DESC
             LIMIT 10;

F.42.5. Authors

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.43. pgcrypto — cryptographic functions

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

`pgcrypto` requires OpenSSL and won't be installed if OpenSSL support was not selected when Postgres Pro was built.

F.43.1. General Hashing Functions

F.43.1.1. `digest()`

```
digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea
```

Computes a binary hash of the given *`data`*. *`type`* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. Moreover, any digest algorithm OpenSSL supports is automatically picked up.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.43.1.2. `hmac()`

```
hmac(data text, key text, type text) returns bytea
hmac(data bytea, key bytea, type text) returns bytea
```

Calculates hashed MAC for *`data`* with key *`key`*. *`type`* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.43.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can coexist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.26 lists the algorithms supported by the `crypt()` function.

Table F.26. Supported Algorithms for `crypt()`

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
`bf`	72	yes	128	60	Blowfish-based, variant 2a
`md5`	unlimited	no	48	34	MD5-based crypt
`xdes`	8	yes	24	20	Extended DES
`des`	8	no	12	13	Original UNIX crypt

F.43.2.1. `crypt()`

```
crypt(password text, salt text) returns text
```

Calculates a crypt(3)-style hash of *`password`*. When storing a new password, you need to use `gen_salt()` to generate a new *`salt`* value. To check a password, pass the stored hash value as *`salt`*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

F.43.2.2. `gen_salt()`

```
gen_salt(type text [, iter_count integer ]) returns text
```

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *`type`* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *`iter_count`* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *`iter_count`* parameter is omitted, the default iteration count is used. Allowed values for *`iter_count`* depend on the algorithm and are shown in Table F.27.

Table F.27. Iteration Counts for `crypt()`

Algorithm	Default	Min	Max
`xdes`	725	1	16777215
`bf`	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.28 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the *`iter_count`* parameter of `gen_salt`.

Table F.28. Hash Algorithm Speeds

Algorithm	**Hashes/sec**	**For** `[a-z]`	**For** `[A-Za-z0-9]`	**Duration relative to** `md5 hash`
`crypt-bf/8`	1792	4 years	3927 years	100k
`crypt-bf/7`	3648	2 years	1929 years	50k
`crypt-bf/6`	7168	1 year	982 years	25k
`crypt-bf/5`	13504	188 days	521 years	12.5k
`crypt-md5`	171584	15 days	41 years	1k
`crypt-des`	23221568	157.5 minutes	108 days	7
`sha1`	37774272	90 minutes	68 days	4
`md5` (hash)	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from mdcrack 1.2.
- `sha1` numbers are from lcrack-20031130-beta.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way the speed with different numbers of iterations can be shown. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.43.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (*RFC 4880*) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.43.3.1. pgp_sym_encrypt()

```
pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea
```

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

F.43.3.2. pgp_sym_decrypt()

```
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.43.3.3. pgp_pub_encrypt()

```
pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea
```

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

F.43.3.4. pgp_pub_decrypt()

```
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns
 bytea
```

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.43.3.5. pgp_key_id()

```
pgp_key_id(bytea) returns text
```

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

  The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

F.43.3.6. `armor()`, `dearmor()`

```
armor(data bytea [ , keys text[], values text[] ]) returns text
dearmor(data text) returns bytea
```

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *`keys`* and *`values`* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.43.3.7. `pgp_armor_headers`

```
pgp_armor_headers(data text, key out text, value out text) returns setof record
```

`pgp_armor_headers()` extracts the armor headers from *`data`*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.43.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.43.3.8.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256, 3des, cast5
Default: aes128
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.43.3.8.2. compress-algo

Which compression algorithm to use. Only available if Postgres Pro was built with zlib.

Values:
0 - no compression
1 - ZIP compression
2 - ZLIB compression (= ZIP plus meta-data and block CRCs)
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.43.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.43.3.8.4. convert-crlf

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt

F.43.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.43.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

F.43.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:
0 - Without salt. Dangerous!
1 - With salt but with fixed iteration count.
3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

F.43.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952
Applies to: pgp_sym_encrypt, only with s2k-mode=3

F.43.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

F.43.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt

F.43.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.43.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on *https://www.gnupg.org/*.

F.43.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.43.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea

encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

algorithm [- *mode*] [/pad: *padding*]

where *algorithm* is one of:

- bf — Blowfish
- aes — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- cbc — next block depends on previous (default)
- ecb — each block is encrypted separately (for testing only)

and *padding* is one of:

- pkcs — data may be any length (default)
- none — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In encrypt_iv and decrypt_iv, the *iv* parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.43.5. Random-Data Functions

```
gen_random_bytes(count integer) returns bytea
```

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

```
gen_random_uuid() returns uuid
```

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the core function of the same name.)

F.43.6. Notes

F.43.6.1. Configuration

pgcrypto configures itself according to the findings of the main Postgres Pro configure script. The options that affect it are --with-zlib and --with-ssl=openssl.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

pgcrypto requires OpenSSL. Otherwise, it will not be built or installed.

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the openssl.cnf configuration file in order to use older ciphers like DES or Blowfish.

F.43.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.43.6.3. Security Limitations

All pgcrypto functions run inside the database server. That means that all the data and passwords move between pgcrypto and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a pgcrypto decryption function to complete varies among ciphertexts of a given size.

F.43.7. Author

Marko Kreen <markokr@gmail.com>

pgcrypto uses code from the following sources:

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com

F.44. pg_freespacemap — examine the free space map

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called pg_freespace, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and roles with privileges of the pg_stat_scan_tables role. Access may be granted to others using GRANT.

F.44.1. Functions

pg_freespace(rel regclass IN, blkno bigint IN) returns int2

Returns the amount of free space on the page of the relation, specified by blkno, according to the FSM.

pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)

Displays the amount of free space on each page of the relation, according to the FSM. A set of (blkno bigint, avail int2) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of BLCKSZ (32 bytes with default BLCKSZ), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is in-use or empty.

F.44.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
 blkno | avail
-------+-------
     0 |     0
     1 |     0
     2 |     0
     3 |    32
     4 |   704
     5 |   704
     6 |   704
     7 |  1216
     8 |   704
     9 |   704
    10 |   704
    11 |   704
    12 |   704
    13 |   704
    14 |   704
    15 |   704
    16 |   704
    17 |   704
    18 |   704
    19 |  3648
(20 rows)

postgres=# SELECT * FROM pg_freespace('foo', 7);
 pg_freespace
--------------
         1216
(1 row)
```

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

F.45. pg_pathman — an optimized partitioning solution for large and distributed databases

> **Important**
>
> Starting from Postgres Pro 12, using pg_pathman is not recommended. Use vanilla declarative partitioning instead, as described in Section 5.11.

The pg_pathman is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using pg_pathman, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

F.45.1. Installation and Setup

The pg_pathman extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable pg_pathman:

1. Add pg_pathman to the shared_preload_libraries variable in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pg_pathman'
   ```

   > **Important**
   >
   > pg_pathman may have conflicts with other extensions that use the same hook functions. For example, pg_pathman may interfere with the pg_stat_statements extension as they both use ProcessUtility_hook. To avoid such issues, pg_pathman must always be the last in the list of libraries: shared_preload_libraries = 'pg_stat_statements, pg_pathman'

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the pg_pathman extension as follows:

   ```
   CREATE SCHEMA pathman;
   GRANT USAGE ON SCHEMA pathman TO PUBLIC;
   CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
   ```

   > **Important**
   >
   > To ensure that your calls to pg_pathman's functions are always secure against search_path-based attacks (see CREATE EXTENSION for details), install it only into a clean schema where nobody except superusers has the CREATE privilege for database objects.

Once pg_pathman is enabled, you can start partitioning tables.

> **Note**
>
> During installation, pg_pathman creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing

`CREATE POLICY` statements are installed. Therefore, when restoring a dump of a database where pg_pathman is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

Tip

You can also build `pg_pathman` from source code by executing the following command in the `pg_pathman` directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the `PG_CONFIG` variable if you want to test `pg_pathman` on a custom build of Postgres Pro. For details, see *Building and Installing PostgreSQL Extension Modules*.

You can toggle `pg_pathman` or its specific custom nodes on and off using GUC variables. For details, see Section F.45.5.1.

If you want to permanently disable `pg_pathman` for a previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

F.45.1.1. Updating pg_pathman

If you already have a previous version of `pg_pathman` installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of `pg_pathman` (the second digit in the version number is different), complete the update as follows:

   ```
   ALTER EXTENSION pg_pathman UPDATE TO version;
   SET pg_pathman.enable = t;
   ```

   where *`version`* is the `pg_pathman` major version number, such as 1.5.

   You can check the current `pg_pathman` version by running the `pathman_version()` function.

F.45.2. Usage

Choosing Partitioning Strategies

Running Non-Blocking Data Migration

Partitioning by a Single Expression

Partitioning by Composite Key

Running Multilevel Partitioning

Using Declarative Syntax

Managing Partitions

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for declarative partitioning was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The `pg_pathman` extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on `pg_pathman` implementation specifics, see Section F.45.4.

F.45.2.1. Choosing Partitioning Strategies

The `pg_pathman` extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, `pg_pathman` uses the binary search algorithm.

By default, `pg_pathman` migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, `pg_pathman` writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see Section F.45.2.2.

F.45.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with `pg_pathman`, run the `create_hash_partitions()` function:

```
create_hash_partitions(parent_relid     REGCLASS,
                       expression       TEXT,
                       partitions_count INTEGER,
                       partition_data   BOOLEAN DEFAULT TRUE,
                       partition_names  TEXT[] DEFAULT NULL,
                       tablespaces      TEXT[] DEFAULT NULL)
```

The `pg_pathman` module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting `partition_names` and `tablespaces` options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition       REGCLASS,
                       new_partition       REGCLASS,
```

```
                          lock_parent         BOOL DEFAULT TRUE);
```

When set to `true`, `lock_parent` parameter will prevent any `INSERT`/`UPDATE`/`ALTER TABLE` queries to parent table.

If you omit the optional `partition_data` parameter or set it to `true`, all the data from the parent table gets migrated to partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the Section F.45.2.2.

F.45.2.1.2. Setting up Range Partitioning

The `pg_pathman` module provides the `create_range_partitions()` for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid   REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     ANYELEMENT | INTERVAL,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data BOOLEAN DEFAULT TRUE)
```

The `pg_pathman` module creates partitions based on the specified parameters. If you omit the optional `p_count` parameter, `pg_pathman` calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, `pg_pathman` creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the `bounds` parameter:

```
create_range_partitions(parent_relid    REGCLASS,
                        expression      TEXT,
                        bounds          ANYARRAY,
                        partition_names TEXT[] DEFAULT NULL,
                        tablespaces     TEXT[] DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)
```

If required, you can also use partition management functions to add partitions manually. For example, if there is a gap between the created partitions, `pg_pathman` cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the Section F.45.2.2.

F.45.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation   REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)
```

where:

- relation is the parent table.
- batch_size is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- sleep_time is the time interval between migration attempts, in seconds.

The pg_pathman module starts a background worker to move the data from the parent table to partitions in small batches of the specified batch_size. If one or more rows in the batch are locked by other queries, pg_pathman waits for the specified sleep_time and tries again, up to 60 times. You can monitor the migration process in the pathman_concurrent_part_tasks view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;
 userid |  pid  | dbid  | relid | processed | status
--------+-------+-------+-------+-----------+---------
 user   | 20012 | 12413 | test  |    334000 | working
(1 row)
```

If you need to stop data migration, run the stop_concurrent_part_task() function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

pg_pathman completes the migration of the current batch and terminates the migration process.

> **Tip**
>
> When pg_pathman migrates all the data from the parent table, you can exclude the parent table from the query plan. See the set_enable_parent() function description for details.

F.45.2.3. Partitioning by a Single Expression

For both range and hash partitioning strategies, pg_pathman supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

> **Tip**
>
> If you would like to partition a table by a tuple, see Section F.45.2.4.

To partition a table by expression, use pg_pathman partitioning functions. The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as NOT NULL.
- Expression cannot reference system attributes, such as oid, xmin, xmax, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as IMMUTABLE.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, pg_pathman cannot optimize the query. You can view the partitioning expression for each partitioned table in the pathman_config table.

F.45.2.3.1. Examples

Suppose you have the `test` table that stores some `jsonb` data:

```
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{"key": %s, "date": "%s", "value": "%s"}',
              i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the `key` value, you need to extract this value from the `jsonb` object and convert it to a numeric type, such as `bigint`:

```
SELECT create_range_partitions('test', '(col->>''key'')::bigint', 1, 10000, 10);
```

`pg_pathman` splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
 parent | partition | parttype |              expr               | range_min |
 range_max
--------+-----------+----------+---------------------------------+-----------
+-----------
 test   | test_1    |        2 | ((col ->> 'key'::text))::bigint | 1         | 10001
 test   | test_2    |        2 | ((col ->> 'key'::text))::bigint | 10001     | 20001
 test   | test_3    |        2 | ((col ->> 'key'::text))::bigint | 20001     | 30001
 test   | test_4    |        2 | ((col ->> 'key'::text))::bigint | 30001     | 40001
 test   | test_5    |        2 | ((col ->> 'key'::text))::bigint | 40001     | 50001
 test   | test_6    |        2 | ((col ->> 'key'::text))::bigint | 50001     | 60001
 test   | test_7    |        2 | ((col ->> 'key'::text))::bigint | 60001     | 70001
 test   | test_8    |        2 | ((col ->> 'key'::text))::bigint | 70001     | 80001
 test   | test_9    |        2 | ((col ->> 'key'::text))::bigint | 80001     | 90001
 test   | test_10   |        2 | ((col ->> 'key'::text))::bigint | 90001     | 100001
(10 rows)
```

F.45.2.4. Partitioning by Composite Key

Using `pg_pathman`, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in Section F.45.2.3.

Although `pg_pathman` does not support automatic partition creation by composite key, you can add partitions using the `add_range_partition()` function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with `pg_pathman` using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

F.45.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
                             '( extract(year from logdate),
                                extract(month from logdate) )::test_key',
                             NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',
                           (extract(year from current_date), 1)::test_key,
                           (extract(year from current_date + '10 years'::interval),
 1)::test_key);
```

F.45.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in Section F.45.2.1, passing the name of the partition to be split as the *`parent_relid`* parameter. You can check the exact partition names in the pathman_partition_list view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

F.45.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- generate some log data into the table
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

-- partition the table by range
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1
 month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1
 day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

F.45.2.6. Using Declarative Syntax

Declarative syntax for partitioning enables you to define the partitioning strategy when creating a table, as well as partition existing tables and manage table partitions using SQL commands. Postgres Pro Enterprise offers the following implementations of declarative syntax:

- Postgres Pro core functionality, described in detail in Section 5.11.2.
- pg_pathman implementation of declarative syntax.

Depending on the chosen implementation, the available SQL command forms will differ, as explained in CREATE TABLE and ALTER TABLE descriptions.

By default, Postgres Pro core functionality is used for declarative partitioning. To enable declarative partitioning provided by `pg_pathman`, set the partition_backend parameter to the `pg_pathman` value. In this case, you can use declarative range and hash partitioning strategies as explained below. For the CREATE TABLE command, you can also override the partition_backend setting by specifying the `USING` *`partition_backend`* clause. Do not confuse this clause with `USING` *`method`*, which cannot be used when creating partitioned tables.

When running the `CREATE TABLE` command, you can use the `PARTITION BY` clause to split the resulting table into partitions by range or hash.

To create a table partitioned by range, specify the partition names, the range of values to include into each partition and, optionally, a tablespace. For example:

```
CREATE TABLE abc(id serial NOT NULL)
    PARTITION BY RANGE(id)
    (
     PARTITION abc_100 VALUES LESS THAN (100) TABLESPACE ts1,
     PARTITION abc_200 VALUES LESS THAN (200) TABLESPACE ts2
    );
```

When creating a table partitioned by hash, you can either specify the number of partitions to create, or the exact partitions and tablespaces. For example, to create the `abc` table with three partitions, run:

```
CREATE TABLE abc(id serial NOT NULL)
    PARTITION BY HASH (id) PARTITIONS (3);
```

To define the exact partitions to create, use the following statement:

```
CREATE TABLE abc(id serial NOT NULL)
    PARTITION BY HASH (id)
    (
     PARTITION abc_first  TABLESPACE ts1,
     PARTITION abc_second TABLESPACE ts2
    );
```

To partition an already created table, you can use the `ALTER TABLE` command with the `PARTITION BY` clause. For example, to split the `abc` table into three hash partitions, run:

```
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3);
```

When performing range partitioning of an already created table, you have to specify the lower bound of the first partition, which must not be greater than the smallest value in the partition key column, and provide the partitioning interval that defines the range of values to include into a single partition:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (2000);
```

If the table to partition contains a lot of data and it is critical to avoid downtime, consider using the optional `CONCURRENTLY` clause. In this case, `pg_pathman` first creates empty partitions, and then migrates the data in batches of 1000 rows. This clause can be used for both hash and range partitioning. For example:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (50000) CONCURRENTLY;
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3) CONCURRENTLY;
```

`pg_pathman` declarative syntax also supports multilevel partitioning. Once the table is partitioned, you can run the `ALTER TABLE` command with the `PARTITION BY` clause on the partition that you would like to split. Consider the following example with hash partitioning:

```
CREATE TABLE test(a int NOT NULL, b int NOT NULL)
    PARTITION BY by hash(a) PARTITIONS (8);

ALTER TABLE test_1
    PARTITION BY hash(b) PARTITIONS (10);
```

As a result, the `test` table is split into eight hash partitions, and its `test_1` partition is further split into ten partitions by another key.

The `ALTER TABLE` command can also be run with partition management clauses to add, remove, or modify partitions, as explained in ALTER TABLE. You can perform these actions on tables partitioned with `pg_pathman` regardless of the partition_backend setting.

F.45.2.7. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see Section F.45.5.3.4.

F.45.3. Examples

F.45.3.1. Common Tips

- You can add `partition` column containing the names of the underlying partitions using the system attribute called `tableoid`:

  ```
  SELECT tableoid::regclass AS partition, * FROM partitioned_table;
  ```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.

- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

  ```
  SELECT * FROM pathman_concurrent_part_tasks;
  userid  | pid  | dbid  | relid | processed | status
  --------+------+-------+-------+-----------+---------
  user    | 7367 | 16384 | test  |    472000 | working
  (1 row)
  ```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

  ```
  SELECT drop_range_partition(partition, false) /* move data to parent */
  FROM pathman_partition_list
  WHERE parent = 'part_test'::regclass AND range_min::int < 500;
  NOTICE:  1 rows copied from part_test_11
  NOTICE:  100 rows copied from part_test_1
  NOTICE:  100 rows copied from part_test_2
  ```

```
drop_range_partition
----------------------
dummy_test_11
dummy_test_1

(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

F.45.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
id       SERIAL PRIMARY KEY,
name     TEXT,
code     BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
  id  |               name               | code
------+----------------------------------+------
 1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
(1 row)

EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
-------------------------------------------------------------------------------------
Append  (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)
Index Cond: (id = 1234)
```

Notice that the `Append` node contains only one child scan, which corresponds to the `WHERE` clause.

> **Important**
>
> Pay attention to the fact that `pg_pathman` excludes the parent table from the query plan.

To access the parent table, use the `ONLY` modifier:

```
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
---------------------------------------------------
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)
```

F.45.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);

-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
id      INTEGER NOT NULL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT)
SERVER archive_server;

SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,
 '2015-01-01'::date);
```

> **Important**
>
> The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and `NOT NULL` settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |         dt          | level |               msg
--------+---------------------+-------+----------------------------------
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)

EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
------------------------------------------------------------------
Append  (cost=0.00..58.80 rows=0 width=0)
->  Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
->  Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

F.45.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are =, <, <=, >, >=), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

F.45.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for INSERT triggers)
- `PartitionRouter` for cross-partition UPDATE queries instead of triggers

`PartitionFilter` acts as a *proxy node* for INSERT's child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
```

```
                QUERY PLAN
----------------------------------------
 Insert on partitioned_table
   ->  Custom Scan (PartitionFilter)
         ->  Subquery Scan on "*SELECT*"
               ->  Result
(4 rows)
```

`PartitionRouter` is another proxy node used in conjunction with `PartitionFilter` to enable cross-partition `UPDATE` operations, for example, when you update any column of a partitioning key.

> **Important**
>
> The `PartitionRouter` node transforms cross-partition `UPDATE` commands into `DELETE` + `INSERT`. On Postgres Pro versions prior to 11, this operation is unsafe as `pg_pathman` cannot determine whether the updated row has been deleted or moved to another partition.

By default, `PartitionRouter` is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to `on`.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
                    QUERY PLAN
--------------------------------------------------
 Update on partitioned_table_0
   ->  Custom Scan (PartitionRouter)
         ->  Custom Scan (PartitionFilter)
               ->  Seq Scan on partitioned_table_0
                     Filter: (value = 2)
(5 rows)
```

`RuntimeAppend` and `RuntimeMergeAppend` have much in common: they come in handy in a case when WHERE condition takes form of:

```
VARIABLE OP PARAM
```

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original `Append`'s code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```

- id = (select ... limit 1)

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
                                                 QUERY PLAN
-------------------------------------------------------------------------------------------
 Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
   InitPlan 1 (returns $0)
     ->  Limit (actual time=0.011..0.011 rows=1 loops=1)
           ->  Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
   ->  Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006
 rows=1 loops=1)
         Filter: (id = $0)
         Rows Removed by Filter: 9
 Planning time: 1.131 ms
 Execution time: 0.075 ms
(9 rows)

/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
                                      QUERY PLAN
---------------------------------------------------------------------------------
 Append (actual time=0.196..0.274 rows=1 loops=1)
   InitPlan 1 (returns $0)
     ->  Limit (actual time=0.005..0.005 rows=1 loops=1)
           ->  Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)

               ->  Seq Scan on some_table (actual time=0.003..0.004 rows=4 loops=1)
 Planning time: 2.169 ms
 Execution time: 2.059 ms
(110 rows)
```

- `NestLoop` **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's *blog*.

F.45.5. Reference

F.45.5.1. GUC Variables

There are several user-accessible GUC variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

  Default: `on`
- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

  Default: `on`
- `pg_pathman.enable_runtimemergeappend` — toggle the `RuntimeMergeAppend` custom node on/off.

  Default: `on`
- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition `INSERT` operations.

  Default: `on`
- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition `UPDATE` operations.

  Default: `off`
- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

  Default: `on`

- `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.

  Default: `on`
- `pg_pathman.insert_into_fdw` — allow `INSERT` operations into various foreign-data wrappers. Possible values: `disabled`, `postgres`, and `any_fdw`.

  Default: `postgres`
- `pg_pathman.override_copy` — toggle `COPY` statement hooking on/off.

  Default: `on`

F.45.5.2. Views and Tables

F.45.5.2.1. `pathman_config`

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (
    partrel         REGCLASS NOT NULL PRIMARY KEY,
    attname         TEXT NOT NULL,
    parttype        INTEGER NOT NULL,
    range_interval  TEXT);
```

F.45.5.2.2. `pathman_config_params`

This table stores optional parameters that override standard `pg_pathman` behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (
    partrel        REGCLASS NOT NULL PRIMARY KEY,
    enable_parent  BOOLEAN NOT NULL DEFAULT TRUE,
    auto           BOOLEAN NOT NULL DEFAULT TRUE,
    init_callback  REGPROCEDURE NOT NULL DEFAULT 0,
    spawn_using_bgw BOOLEAN NOT NULL DEFAULT FALSE);
```

F.45.5.2.3. `pathman_concurrent_part_tasks`

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()
RETURNS TABLE (
    userid     REGROLE,
    pid        INT,
    dbid       OID,
    relid      REGCLASS,
    processed  INT,
    status     TEXT)
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_concurrent_part_tasks
AS SELECT * FROM show_concurrent_part_tasks();
```

F.45.5.2.4. `pathman_partition_list`

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_partition_list()
RETURNS TABLE (
    parent     REGCLASS,
    partition  REGCLASS,
```

```
    parttype   INT4,
    expr       TEXT,
    range_min  TEXT,
    range_max  TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

F.45.5.3. Functions

F.45.5.3.1. Partitioning Functions

```
create_hash_partitions(parent_relid     REGCLASS,
                       expression       TEXT,
                       partitions_count INTEGER,
                       partition_data   BOOLEAN DEFAULT TRUE,
                       partition_names  TEXT[] DEFAULT NULL,
                       tablespaces      TEXT[] DEFAULT NULL)
```

Performs hash partitioning for `relation` by integer key `expression`. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is `true`, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation       REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     ANYELEMENT,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data BOOLEAN DEFAULT TRUE)

create_range_partitions(relation       REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     INTERVAL,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data BOOLEAN DEFAULT TRUE)

create_range_partitions(relation        REGCLASS,
                        expression      TEXT,
                        bounds          ANYARRAY,
                        partition_names TEXT[] DEFAULT NULL,
                        tablespaces     TEXT[] DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)
```

Performs range partitioning for `relation` by partitioning key defined by `expression`. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the `expression` value. The `bounds` array defines the bounds for partitions to be created. You can build this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

F.45.5.3.2. Data Migration Functions

```
partition_table_concurrently(relation REGCLASS,
```

```
                                batch_size INTEGER DEFAULT 1000,
                                sleep_time FLOAT8 DEFAULT 1.0)
```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```
stop_concurrent_part_task(relation REGCLASS)
```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

F.45.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of BEFORE/AFTER INSERT trigger functions of a corresponding partition.
- Each updated row results in execution of BEFORE/AFTER UPDATE trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of BEFORE UPDATE + BEFORE/AFTER DELETE + BEFORE/AFTER INSERT trigger functions of corresponding partitions.

F.45.5.3.4. Partition Management Functions

```
replace_hash_partition(old_partition       REGCLASS,
                       new_partition       REGCLASS,
                       lock_parent         BOOLEAN DEFAULT TRUE)
```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT`/`UPDATE`/`ALTER TABLE` queries to the parent table.

```
split_range_partition(partition_relid  REGCLASS,
                      split_value      ANYELEMENT,
                      partition_name   TEXT DEFAULT NULL,
                      tablespace       TEXT DEFAULT NULL)
```

Split range `partition` in two by `value`, with the specified `value` included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid   REGCLASS,
                       partition_name TEXT DEFAULT NULL,
                       tablespace     TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid   REGCLASS,
                        partition_name TEXT DEFAULT NULL,
                        tablespace     TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid   REGCLASS,
                    start_value    ANYELEMENT,
```

```
                    end_value      ANYELEMENT,
                    partition_name TEXT DEFAULT NULL,
                    tablespace     TEXT DEFAULT NULL)
```

Create a new range partition for `relation` with the specified range bounds. If the `start_value` or the `end_value` is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid    REGCLASS,
                       partition_relid REGCLASS,
                       start_value     ANYELEMENT,
                       end_value       ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see Section F.45.5.2.2).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,
                delete_data  BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is `false`, the data is copied to the parent table first. Default is `false`.

F.45.5.3.5. Additional Functions

```
pathman_version()
```

Returns the `pg_pathman` version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
{
    "parent":    "abc",
    "parttype":  "2",
    "partition": "abc_4",
    "range_max": "401",
    "range_min": "301"
}

/* Hash-partitioned table abc (child abc_0) */
{
    "parent":    "abc",
    "parttype":  "1",
    "partition": "abc_0"
}
```

```
set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When inserting new data beyond the partitioning range, use SpawnPartitionsWorker to create new partitions in a separate transaction.

```
create_naming_sequence(parent_relid REGCLASS)
```

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

```
add_to_pathman_config(parent_relid     REGCLASS,
                      expression       TEXT,
                      range_interval   TEXT)
add_to_pathman_config(parent_relid     REGCLASS,
                      expression       TEXT)
```

Register the specified `relation` table with `pg_pathman` to enable partitioning by the provided `expression`. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start     ANYELEMENT,
                      p_interval  INTERVAL,
                      p_count     INTEGER)

generate_range_bounds(p_start     ANYELEMENT,
                      p_interval  ANYELEMENT,
                      p_count     INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

F.46. pgpro_application_info — port applications using DBMS_APPLICATION_INFO package

pgpro_application_info is an extension designed to help developers who port applications using the DBMS_APPLICATION_INFO package from Oracle to Postgres Pro. It can also be used by database administrators as an additional source of data when analyzing performance and by developers when debugging.

pgpro_application_info creates procedures and functions that an application can use to report its status, performed actions, and action progress. The database administrator can access this information through specific views.

The typical sequence of client actions reporting to pgpro_application_info will look like this (in the example, a librarian wants to count all the words “the” in the library):

1. Once the client makes a connection to the database, it registers itself as the `Librarian` and runs the scanner application, which, in its turn, registers itself as the `Book Scanner` module and indicates that it is currently attempting to perform `Book Scanning` to find all occurrences of the word “the” in 18042 books, having completed 0 scans as of now.
2. Having scanned a few books, the application updates the information to reflect its progress.
3. When the scanning is completed, the application registers this fact and sets its current action as `Idle` (or NULL).

F.46.1. Installation

The `pgpro_application_info` extension is a built-in extension included into Postgres Pro Enterprise. To enable `pgpro_application_info`, do the following:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'pgpro_application_info'
   ```

2. Reload the database server for the changes to take effect.

   > **Note**
   >
   > To verify that the library was installed correctly, you can run the following command:
   >
   > ```
   > SHOW shared_preload_libraries;
   > ```

3. Create the extension using the following query:

   ```
   CREATE EXTENSION pgpro_application_info;
   ```

F.46.2. Usage

pgpro_application_info handles the following main data classes:

- Application Data: current module name, performed action, and client description. The database administrator can access the information about active clients and their actions via the V_SESSION view.
- Information about Long Operations: textual descriptions and comments, operation progress report and optionally the link to the database object in question. The database administrator can access the information about long operations via the V_SESSION_LONGOPS view, which in addition to the data sent by the client contains operation start and latest update timestamps, as well as the estimated time remaining.

> **Note**
>
> Note that in Oracle's DBMS_APPLICATION_INFO textual parameters supplied by the user have various maximum length up to 64 bytes, but for convenience in pgpro_application_info all of them have the same maximum length of 64 bytes. Exceeding information is truncated.

F.46.2.1. Application Data

To set application information, pgpro_application_info provides the following procedures:

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_CLIENT_INFO(client_info TEXT)
```

Sets the client information. This is typically the client name or a more complex description, but strictly speaking, it can be any text provided by the user.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_ACTION(action_name TEXT)
```

Sets the name of the executed action in the current module.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_MODULE(module_name TEXT, action_name TEXT DE-
FAULT NULL)
```

Sets the name of the current module (program) and action. When the program terminates, call this procedure with the name of the next module if there is one, or NULL otherwise.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.READ_CLIENT_INFO(OUT client_info TEXT)
```

Returns the client information previously set by SET_CLIENT_INFO in the current session.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.READ_MODULE(OUT module_name TEXT, OUT action_name
TEXT)
```

Returns the module information previously set by SET_MODULE and action information set by SET_MODULE or SET_ACTION in the current session.

F.46.2.1.1. The V_SESSION View

The V_SESSION view provides the information about all the active sessions reported via pgpro_application_info procedures, the connected clients, modules, and current actions. The view contains one row for each distinct session. When a session reports its information for the first time, the corresponding view entry is created. Each row exists during the corresponding session lifetime so the view is empty after server restart. The columns of the view are shown in Table F.29. For ease of use, Postgres Pro also provides an equivalent view called V$SESSION, familiar to Oracle users, which contains the same information. Note, however, that better compatibility with Oracle provided by this alternative is a deviation from the SQL standard and, consequently, makes the code less portable.

```
CREATE FUNCTION DBMS_APPLICATION_INFO.READ_V_SESSION(
    OUT SID INTEGER,
    OUT DBNAME TEXT,
    OUT MODULE TEXT,
    OUT ACTION TEXT,
    OUT CLIENT_INFO TEXT
)
CREATE VIEW V_SESSION AS SELECT * FROM DBMS_APPLICATION_INFO.READ_V_SESSION();
```

Table F.29. V_SESSION Columns

Name	Description
SID	Session ID, PID

Name	Description
DBNAME	Name of the database the session is connected to. If you want to view the entries only for the current database, add the following condition to the query: WHERE DBNAME=current_database() .
MODULE	Name of the module executed by the session that was previously set by SET_MODULE .
ACTION	Name of the action executed by the session that was previously set by SET_MODULE or SET_ACTION.
CLIENT_INFO	Information about the client associated with the session that was previously set by SET_CLIENT_INFO.

F.46.2.2. Information about Long Operations

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_SESSION_LONGOPS(
                INOUT RINDEX INTEGER,
                INOUT SLNO INTEGER,
                OP_NAME TEXT DEFAULT NULL,
                TARGET OID DEFAULT 0,
                CONTEXT INTEGER DEFAULT 0,
                SOFAR DOUBLE PRECISION DEFAULT 0,
                TOTALWORK DOUBLE PRECISION DEFAULT 0,
                TARGET_DESC TEXT DEFAULT 'unknown target',
                UNITS TEXT DEFAULT NULL
            )
```

The SET_SESSION_LONGOPS procedure creates a new row (or updates the existing one) in the V_SESSION_LONGOPS view. Each row contains information about a single long operation (typically longer than 6 seconds): its description, the accessed objects, and the estimated time remaining.

- *RINDEX*: A token which represents the row in the V_SESSION_LONGOPS view. To start a new row, set this to the result of the DBMS_APPLICATION_INFO.SET_SESSION_LONGOPS_NOHINT() function. When you call SET_SESSION_LONGOPS to update the existing row, set this to the returned value from the prior call.
- *SLNO*: Internal information saved between calls. To start a new row, set this to NULL. When you call SET_SESSION_LONGOPS to update the existing row, set this to the returned value from the prior call.
- *OP_NAME*: Short description of the performed operation, usually its name.
- *TARGET*: OID of the object that is being worked on during the long-running operation.
- *CONTEXT*: Any number the user wants to store.
- *SOFAR*: Any number the user wants to store. This is typically the amount of work which has been done so far.
- *TOTALWORK*: Any number the user wants to store. This is typically the amount of work to be done.
- *TARGET_DESC*: The description of the object that is being worked on during the long-running operation (*TARGET*).
- *UNITS*: The units in which *SOFAR* and *TOTALWORK* are represented.

SOFAR and *TOTALWORK* values are used to calculate the estimated time remaining in the V_SESSION_LONGOPS view, but valid values are any numbers so if they are inconsistent (for example, both values are negative, or *TOTALWORK*=0), the estimated time remaining will not be calculated.

F.46.2.2.1. The V_SESSION_LONGOPS View

The V_SESSION_LONGOPS view provides the information about long operations previously passed by SET_SESSION_LONGOPS. The view contains one row for each distinct long operation. Each row exists until it is rewritten or the server is shut down. The view is empty after server restart. The columns of the view are shown in Table F.30. For ease of use, Postgres Pro also provides an equivalent view called V$SESSION_LONGOPS, familiar to Oracle users, which contains the same information. Also, the P_TIMESTAMP column was renamed TIMESTAMP in this view. Note, however, that better compatibility with Oracle provided by these alternatives is a deviation from the SQL standard and, consequently, makes the code less portable.

```
CREATE FUNCTION DBMS_APPLICATION_INFO.READ_V_SESSION_LONGOPS(
    OUT SID INTEGER,
    OUT SERIAL_N INTEGER,
    OUT DBNAME TEXT,
    OUT OPNAME TEXT,
    OUT TARGET OID,
    OUT TARGET_DESC TEXT,
    OUT SOFAR DOUBLE PRECISION,
    OUT TOTALWORK DOUBLE PRECISION,
    OUT UNITS TEXT,
    OUT START_TIME TIMESTAMP,
    OUT LAST_UPDATE_TIME TIMESTAMP,
    OUT P_TIMESTAMP TIMESTAMP,
    OUT TIME_REMAINING INTEGER,
    OUT ELAPSED_SECONDS INTEGER,
    OUT CONTEXT INTEGER,
    OUT MESSAGE TEXT,
    OUT USERNAME TEXT
)
CREATE VIEW V_SESSION_LONGOPS AS SELECT * FROM
 DBMS_APPLICATION_INFO.READ_V_SESSION_LONGOPS();
```

Table F.30. V_SESSION_LONGOPS Columns

Name	Description
SID	ID of the session processing the long-running operation.
SERIAL_N	Synonym for SID. Added for Oracle-compatibility reasons.
DBNAME	Name of the database the session is connected to. If you want to view the rows only for the current database, add the following condition to the query: WHERE DBNAME=current_database() .
OPNAME	Short description of the performed operation, usually its name.
TARGET	OID of the object that is being worked on during the long-running operation.
TARGET_DESC	The description of the object that is being worked on during the long-running operation (TARGET).
SOFAR	The amount of work which has been done so far in units specified in UNITS.
TOTALWORK	The amount of work to be done in units specified in UNITS.
UNITS	The units in which SOFAR and TOTALWORK are represented.

Name	Description
START_TIME	Operation start time (or the time the row was created).
LAST_UPDATE_TIME	Last row update time.
P_TIMESTAMP	Synonym for LAST_UPDATE_TIME . Added for Oracle-compatibility reasons. For convenience, you can use another parameter name by adding an alias. For example, to create a TIMESTAMP alias, add SELECT P_TIMESTAMP AS TIMESTAMP to the view definition.
TIME_REMAINING	Estimate of time remaining for the operation to complete (in seconds). Calculated based on SOFAR and TOTALWORK values. The estimated time remaining will not be calculated, if these values are inconsistent, SOFAR=0, or LAST_UPDATE_TIME is the same as START_TIME .
ELAPSED_SECONDS	Number of elapsed seconds from the operation start (row creation).
CONTEXT	The number set by the user as the context.
MESSAGE	Statistics summary message about the operation progress.
USERNAME	Name of the user performing the operation.

F.46.3. Example

In our simple example, the application represents a lazy boy counting crows:

```
DO $$
DECLARE
    rindex integer := DBMS_APPLICATION_INFO.SET_SESSION_LONGOPS_NOHINT();
    slno integer := NULL;
    total_crows integer := 146;
BEGIN
    CALL DBMS_APPLICATION_INFO.SET_CLIENT_INFO('Lazy boy');
    CALL DBMS_APPLICATION_INFO.SET_MODULE('Crow counter', 'Prepare');

    PERFORM pg_sleep(2);

    CALL DBMS_APPLICATION_INFO.SET_ACTION('Count');

    FOR i IN 1..total_crows LOOP
        CALL DBMS_APPLICATION_INFO.SET_SESSION_LONGOPS(
            RINDEX=>rindex,
            SLNO=>slno,
            OP_NAME=>'Counting birds',
            CONTEXT=>42,
            SOFAR=>i,
            TOTALWORK=>total_crows,
            UNITS=>'birds'
        );
        PERFORM pg_sleep(0.4);
    END LOOP;

    CALL DBMS_APPLICATION_INFO.SET_ACTION(NULL);
END$$;
```

If you run this code in psql and access V_SESSION and V_SESSION_LONGOPS in another session, you can get the following output:

```
postgres=# select * from v_session_longops;
 sid | serial_n | dbname | opname | target | target_desc | sofar | totalwork | units
 | start_time | last_update_time | p_timestamp | time_remaining | elapsed_seconds |

F.47. pgpro_bfile — a composite type to access an external file

The pgpro_bfile extension introduces a composite type bfile that implements an Oracle-like technique to access an external file.

F.47.1. Data Structures

The bfile type contains two fields:

- dir_id — the directory identifier in the bfile_directories table
- file_name — the name of the external file

Information on directories is stored in the bfile_directories table, which has the following columns:

- dir_id — a unique directory identifier of the int32 type.
- dir_alias — a unique directory alias.
- dir_path — path to the directory.

Although having two unique identifiers dir_id and dir_alias is excessive, dir_id is best for storing in bfile because it requires less storage and ensures faster search, while working with dir_alias is more convenient for a user migrating from Oracle, especially to better understand command semantics.

Information on directory access rights is stored in the bfile_directory_roles table, which has the following columns:

- dr_dir_id — a directory identifier of the int32 type, that is, an external reference to the dir_id column in the bfile_directories table.
- dr_role_id — ID of a user/role that has access rights on the directory.
- dr_rights — a bit array of access rights on the directory (1 means read access, 2 means write access). Choice of a bit array assumes that a need to grant new access rights can arise, such as a need in a separate delete right.

F.47.2. Functions

Functions to work with directories and to manage directory access rights are implemented in PL/PgSQL, while functions to work with bfile values are implemented in C for better performance.

Table F.31. Functions for Working with Directories

Function Description
bfile_directory_create (*a_dir_alias* text, *a_dir_path* text) returns (int) Creates a directory for the given alias and path and returns the ID of the created directory. Superuser privileges are required to call this function.
bfile_directory_delete (*a_dir_alias* text) returns (void) Deletes the directory with the given alias. Superuser privileges are required to call this function.
bfile_directory_rename (*a_dir_alias* text, *a_new_dir_alias* text) returns (void) Changes the alias of the directory. Superuser privileges are required to call this function.
bfile_directory_set_path (*a_dir_alias* text, *a_dir_path* text) returns (void) Changes the path to the directory with the given alias. Superuser privileges are required to call this function.
bfile_directory_get_path_by_alias (*a_dir_alias* text) returns (text) Returns the path to the directory with the given alias.

Function Description
`bfile_directory_get_path_by_id ( a_dir_id int) returns ( text)` Returns the path to the directory with the given ID.
`bfile_directory_get_alias_by_id ( a_dir_id int) returns ( text)` Returns the alias of the directory with the given ID.
`bfile_directory_get_id_by_alias ( a_dir_alias text) returns ( int)` Returns the ID of the directory with the given alias.

Table F.32. Functions for Granting and Revoking Directory Access Rights

Function Description
`bfile_grant_directory ( a_dir_alias text, a_role_name text, a_access_mask int) returns ( void)` Grants access rights on the *a_dir_alias* directory to the *a_role_name* user/role. *a_access_mask* specifies the access to grant (1 — read, 2 — write, 3 — read and write). Superuser privileges are required to call this function.
`bfile_revoke_directory ( a_dir_alias text, a_role_name text, a_access_mask int) returns ( void)` Revokes access rights on the *a_dir_alias* directory form the *a_role_name* user/role. *a_access_mask* specifies the access to revoke (1 — read, 2 — write, 3 — read and write). Superuser privileges are required to call this function.
`bfile_cleanup_directory_roles () returns ( void)` Removes information on directory access rights of deleted users/roles from the `bfile_directory_roles` table. Superuser privileges are required to call this function.

Table F.33. Functions for Working with `bfile` Values

Function Description
`bfile_make ( a_dir_alias text, a_file_name text) returns ( bfile)` Returns the `bfile` structure for the given directory alias and filename.
`bfile_make_dir_id ( a_dir_id int, a_file_name text) returns ( bfile)` Returns the `bfile` structure for the given directory ID and filename.
`bfile_open ( a_bfile bfile[, a_access_mask int]) returns ( int)` Opens the file for the given *a_bfile* and returns its descriptor. *a_access_mask* specifies the file access mode (1 — read, 2 — write, 3 — read and write), the default is 1.
`bfile_close ( a_handler int) returns ( void)` Closes the file for the given descriptor returned by the `bfile_open` function.
`bfile_close_all () returns ( int)` Closes all the files that were opened earlier by the `bfile_open` function. Returns the number of closed files.
`bfile_length ( a_handler int) returns ( bigint)` Returns the size of the open file with the given descriptor.
`bfile_read ( a_handler int[, a_offset bigint, a_length bigint]) returns ( bytea)` From the open file with the descriptor *a_handler* , reads *a_length* bytes at the *a_offset* offset from the beginning of file and returns the bytes read. By default, *a_length* is -1, which specifies reading to the end of file, and *a_offset* is 0, which specifies reading from the beginning of file.
`bfile_write ( a_handler int, a_buffer bytea[, a_offset bigint]) returns ( void)`

Function Description
Writes the given buffer *a_buffer* to the open file having the given descriptor *a_handler* at the given *a_offset* offset from the beginning of file. By default, *a_offset* is -1, which means writing from the end of file.
bfile_fileexists (*a_bfile* bfile) returns (boolean) Returns true if the file corresponding to *a_bfile* can be used. The function checks that the file opens without errors.
bfile_length_direct (*a_bfile* bfile) returns (bigint) Returns the file size for the given *a_bfile* .
bfile_read_direct (*a_bfile* bfile[, *a_offset* bigint, *a_length* bigint]) returns (bytea) For the given *a_bfile* , reads *a_length* bytes at the *a_offset* offset from the beginning of file and returns the bytes read. By default, *a_length* is -1, which means reading to the end of file, and *a_offset* is 0, which means reading from the beginning of file.
bfile_write_direct (*a_bfile* bfile, *a_buffer* bytea) returns (void) For the given *a_bfile* , writes the given buffer *a_buffer* to a new file. Write access to the *a_bfile* directory is required.
bfile_delete (*a_bfile* bfile) returns (void) Deletes the file for the given *a_bfile* . Write access to the *a_bfile* directory is required.
bfile_compare (*a_bfile_1* bfile, *a_bfile_2* bfile[, *a_amount* bigint, *a_offset_1* bigint, *a_offset_2* bigint]) returns (int) When *a_amount* , *a_offset_1* and *a_offset_2* are not specified, if the sizes of *a_bfile_1* and *a_bfile_2* files are different, returns -1 if the size of *a_bfile_1* is less than the size of *a_bfile_2* and 1 otherwise. If the files have equal sizes, the function performs byte-wise comparison of the file data and returns 0 if the comparison shows equal data, -1 if the data in *a_bfile_1* is less than in *a_bfile_2* and 1 if the data in *a_bfile_1* is greater than in *a_bfile_2* . *a_amount* specifies the number of bytes in the given bfile values to compare, while *a_offset_1* and *a_offset_2* specify the offsets to start the comparison at.
bfile_md5 (*a_bfile* bfile) returns (text) Calculates an MD5 hash for the specified bfile object and returns the result as a 16-byte value in text form.

F.47.3. Example

The following example illustrates usage of the bfile type.

We will run a script on the server file system. But first, let's create a directory to store bfile data:

```
mkdir "/tmp/bfiles"
```

Now we will use psql to run the script below:

```
-- Create the pgpro_bfile extension:
CREATE EXTENSION pgpro_bfile;

-- Create a directory in the database to store bfile:
SELECT bfile_directory_create('BFILE_DATA', '/tmp/bfiles');

-- Create the file bfile.data on the file system and add there the value of
 '0123456789':
SELECT bfile_write_direct(bfile_make('BFILE_DATA', 'bfile.data'), '0123456789');

-- Create the table bfile and add there one record referencing that file:
CREATE TABLE bfile_table(id int, bf bfile);
```

```
INSERT INTO bfile_table VALUES (1, bfile_make('BFILE_DATA', 'bfile.data'));

-- Create a user to run the script:
CREATE USER bf_test_user;

-- Grant bf_test_user with read-write access to BFILE_DATA:
SELECT bfile_grant_directory('BFILE_DATA', 'bf_test_user', 3);

-- Grant bf_test_user with rights on bfile_table:
GRANT ALL ON bfile_table TO bf_test_user;

-- Register as bf_test_user:
SET SESSION AUTHORIZATION bf_test_user;

DO $$
DECLARE
  v_bfile bfile;
  v_buffer bytea;
  v_length bigint;
  v_handler int;
BEGIN
  -- Open the file for reading and writing:
  SELECT bfile_open(bf, 3) INTO v_handler FROM bfile_table WHERE id = 1;

  -- This character string will be written to end of file:
  PERFORM bfile_write(v_handler, '_suffix');
  -- This character string will be written from the position 0 and replace '0123456':
  PERFORM bfile_write(v_handler, 'prefix_', 0);

  -- Read the character string from file to a buffer and print out its length and
 contents:
  v_buffer = bfile_read(v_handler);
  RAISE NOTICE 'Buffer length: %', length(v_buffer);
  RAISE NOTICE 'Buffer content: %', encode(v_buffer, 'escape');

  -- Get and print out the file size:
  v_length = bfile_length(v_handler);
  RAISE NOTICE 'BFILE length: %', v_length;

  -- Close bfile:
  PERFORM bfile_close(v_handler);
END $$;

-- Check the contents of the table:
SELECT encode(b, 'escape'), length(b) from (SELECT bfile_read_direct(bf) b FROM
 bfile_table) x;

-- Delete the table, user and pgpro_bfile extension:
RESET SESSION AUTHORIZATION;
DROP TABLE bfile_table;
DROP USER bf_test_user;
DROP EXTENSION pgpro_bfile;
```

The script produces the following output:

```
 CREATE EXTENSION
 bfile_directory_create
------------------------
                      1
```

```
(1 row)

 bfile_write_direct
--------------------

(1 row)

CREATE TABLE
INSERT 0 1
CREATE ROLE
 bfile_grant_directory
-----------------------

(1 row)

GRANT
SET
NOTICE:  Buffer length: 17
NOTICE:  Buffer content: prefix_789_suffix
NOTICE:  BFILE length: 17
DO
      encode       | length
-------------------+--------
 prefix_789_suffix |     17
(1 row)

RESET
DROP TABLE
DROP ROLE
DROP EXTENSION
```

F.48. pg_proaudit — enables detailed logging of various security events

The pg_proaudit extension enables detailed logging of various security events.

pg_proaudit works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the pg_proaudit extension is stored separately from the server log. At the Postgres Pro Enterprise startup, pg_proaudit launches a special background process to log security events.

Logging rules are stored in the pg_proaudit.conf configuration file located in the cluster data directory (PGDATA). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several pg_proaudit functions. The pg_proaudit_settings view displays the current pg_proaudit rules, even if they have not been saved into the pg_proaudit.conf file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tablespaces, schemas, tables, views, sequences, languages, functions)
- access control commands for database objects (GRANT, REVOKE)
- DML commands for access to database objects (INSERT, UPDATE, DELETE, SELECT, TRUNCATE for tables and/or views, EXECUTE for functions)
- database authentication/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. For clear identification, all pg_proaudit records in the syslog are marked with AUDIT. Event log files are written in the CSV format. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- current user name
- database name
- server process ID (PID)
- severity level: INFO or ERROR
- serial number of the command in a session
- subcommand number in complex commands (CREATE TABLE ... AS SELECT ...)
- operator name
- object type
- object name
- operator execution results: SUCCESS or FAILURE
- additional information like error message in case of FAILURE or connection parameters for the AUTHENTICATE event; unfinished authentication attempts are marked as [EOF. No credentials provided]
- text of the SQL command
- parameters of the command (for example, for PREPARE)
- session user name
- unique ID of the event (in the *UUIDv7* format)
- transaction ID (XID)
- virtual transaction ID (VXID)

An event contains the information about both session_user and current_user of the session. Therefore, it will be possible to identify the user, even if they execute the SET ROLE command to change user identifier.

The XID and VXID values can be zero if an event does not relate to a transaction (e. g. the DISCONNECT event).

You can define a directory to store security log files and set up log file rotation. pg_proaudit can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the SUPERUSER attribute should grant access to the pg_proaudit extension and security event log files only to the user with the information security administrator role.

F.48.1. Installing the pg_proaudit Extension

The pg_proaudit extension is a built-in extension included into Postgres Pro Enterprise. To enable pg_proaudit, complete the following steps:

1. Add pg_proaudit to the shared_preload_libraries variable in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pg_proaudit'
   ```

2. Restart the database server for the changes to take effect. To verify that the pg_proaudit library was installed correctly, you can run the following command:

   ```
   SHOW shared_preload_libraries;
   ```

3. In each database for which you are going to log security events, create the pg_proaudit extension using the following query:

   ```
   CREATE EXTENSION pg_proaudit;
   ```

   The pg_proaudit extension adds several functions for managing the pg_proaudit.conf file, the pg_proaudit_settings view that displays the current pg_proaudit rules and event triggers.

F.48.2. Uninstalling the pg_proaudit Extension

To properly uninstall pg_proaudit, complete the following steps:

1. Delete the pg_proaudit extension using the following query:

   ```
   DROP EXTENSION pg_proaudit;
   ```

2. Remove pg_proaudit from the shared_preload_libraries variable in the postgresql.conf file.

   Skip this step if you have several databases in the cluster and you want to remove the extension only for one of them. In this case, it is recommended to remove logging rules related to the corresponding database prior to uninstalling the extension.

F.48.3. Functions to Configure Security Event Logging

To configure security event logging, pg_proaudit provides an SQL interface that consists of several functions and the pg_proaudit_settings view.

```
pg_proaudit_set_rule(db_name text, event_type text, object_type text, object_name text,
 role_name text, comment text)
```

Creates the logging rule with the specified parameters. When the pg_proaudit_set_rule() function completes, security event logging starts immediately, but the pg_proaudit.conf file is not updated. To save the changes in the pg_proaudit.conf file, call the pg_proaudit_save() function.

Arguments:

- *db_name* — name of the database for which the logging rule is established. An empty string or NULL specified in this argument means that events are logged for all databases where the pg_proaudit extension is created. When set to current_database(), events for the current database are logged.
- *event_type* — type of the event that needs to be logged, including SQL operator names, as well as AUTHENTICATE and DISCONNECT events. When set to ALL, as well as when an empty string or NULL

is specified, enables logging for all events available for the specified object type. For example, for the TABLE object type, the ALL keyword enables logging for commands SELECT, INSERT, UPDATE, DELETE, TRUNCATE, COPY, as well as CREATE, ALTER, DROP. You can also set up logging of event classes by specifying the following values: ALL_DDL, ALL_DDL_NONTEMP, ALL_DML, ALL_DML_NONTEMP, ALL_MOD, ALL_PROC, and ALL_ROLE. For the full list of possible *event_type* values, see Section F.48.5.

- *object_type* — type of the object for which security events need to be logged. When set to ALL, as well as when an empty string or the NULL is specified, enables logging of events for all object types. For example, specify FOREIGN TABLE object type for the SELECT event to log all attempts to access foreign tables. Use NULL if *event_type* is set to AUTHENTICATE, DISCONNECT, SET, or RESET, and the ROLE value for all events that reference user actions, such as CREATE USER or DROP USER. The following object types are supported: COMPOSITE TYPE, DATABASE, EVENT TRIGGER, FUNCTION, INDEX, PREPARED STATEMENT, ROLE, SEQUENCE, SCHEMA, TABLE, FOREIGN TABLE, TOAST TABLE, TABLESPACE, VIEW, MATERIALIZED VIEW, CATALOG RELATION, and CATALOG FUNCTION.

> **Note**
>
> To log security events for system catalog objects, it is required to enable the pg_proaudit.log_catalog_access configuration parameter. Otherwise, these events will not be logged, even if the CATALOG RELATION, CATALOG FUNCTION, or ALL object type is specified in the rule.

- *object_name* — name of the object for which the logging rule is established. When an empty string or NULL is specified, enables logging of events for all object names.
- *role_name* — name of the role for which the logging rule is established. If specified, allows logging the actions caused by the user who has the privileges of the role. This means that at least one of the user session attributes, session_user or current_user, should either be equal to the role_name, or be directly or indirectly a member of this role. When an empty string or NULL is specified, enables logging of actions caused by any user. When set to current_role, the logging rule is established for the user current role.
- *comment* — comment to describe the created logging rule. This argument does not affect the rule execution and is not reflected in the log.

```
pg_proaudit_remove_rule(db_name text, event_type text, object_type text, object_name
 text, role_name text)
```

Removes the specific logging rule with the set parameters. To save the changes in the pg_proaudit.conf file, call the pg_proaudit_save() function.

> **Note**
>
> If the rule that you want to remove is configured to log the DISCONNECT event type, then disconnect events may still be logged after the rule is removed. For additional information, see Section F.48.3.1.

Arguments:

- *db_name* — name of the database for which the logging rule needs to be removed.
- *event_type* — type of the event for which the logging rule needs to be removed. For the full list of possible *event_type* values, see Section F.48.5.
- *object_type* — type of the object for which the logging rule needs to be removed.
- *object_name* — name of the object for which the logging rule needs to be removed.
- *role_name* — name of the role for which the logging rule needs to be removed.

```
pg_proaudit_show()
```

Returns logged events in a table view. This function is used by the pg_proaudit_settings view.

```
pg_proaudit_reload()
```

Reads logging configuration from the pg_proaudit.conf file. You must call this function if the pg_proaudit.conf file was modified manually using the operating system facilities.

pg_proaudit_reset()

Removes all logging rules. To save information about the canceled logging in the pg_proaudit.conf file, call the pg_proaudit_save() function.

pg_proaudit_save()

Saves logging rules from memory into the pg_proaudit.conf file. The pg_proaudit.conf file is located in the cluster data directory (PGDATA). You cannot change the pg_proaudit.conf file location.

F.48.3.1. Handling Database Disconnection Events

When a logging rule is configured for DISCONNECT event type, and a user authenticates in a database, then the pg_proaudit extension checks whether the corresponding disconnection event satisfies the rule and must be logged.

If the event must be logged, then the removal of the logging rule has no effect on the event. This event will be logged no matter if the logging rule exists at the moment of disconnect.

Consider the following example:

1. An administrator configures the following logging rule:

   ```
   SELECT pg_proaudit_set_rule ('postgres', 'DISCONNECT', null, null, null, 'Any
    disconnect from the postgres DB');
   ```

2. A user connects to the postgres database and goes through authentication.

   For the rule in effect, a corresponding disconnection event will be logged later.

3. The administrator removes the logging rule, while the user is still connected to the database:

   ```
   SELECT pg_proaudit_remove_rule('postgres', 'DISCONNECT', null, null, null);
   ```

4. The user disconnects from the database.

   The corresponding disconnection event is logged despite the removal of the logging rule.

F.48.3.2. Handling Object Names

Comparison of string representations of names for database, user, role and other objects is case-insensitive even if the object name in the database is enclosed in quotes. These string representations are stored as lower-case strings.

Strings representing object names need to be passed to functions pg_proaudit_set_rule and pg_proaudit_remove_rule as regular strings: a single quote needs repeating, and other characters are passed as is, without escaping or wrapping.

For example, rules for tables table1 and "TaBlE1" will be the same, and their names can be passed in upper-case or lower-case characters. The same holds for roles. As for databases, before creating a rule, pg_proaudit checks whether this database actually exists, and this check is case-sensitive.

The following examples illustrate creation of "weird" object names and specifying correct audit rules for them.

```
create table "TAbLe''123"();
SELECT pg_proaudit_set_rule(current_database(), null, null, 'public.TabLe''''123',
 null, 'tst cmnt');

create table "taBlE""123"();
```

```
SELECT pg_proaudit_set_rule(null, null, null, 'public.taBlE"123', null);

create schema "(BIG!) Schema";
create table "(BIG!) Schema"."My Tab.lE"();
SELECT pg_proaudit_set_rule(null, null, null, '(BIG!) Schema.My Tab.lE', null);

create role "Some '@#$%' person" with login;
SELECT pg_proaudit_set_rule(null, 'authenticate', null, null, 'Some ''@#$%'' person');

create role "Some '@#$%' person" with superuser;
\c - "Some '@#$%' person"
SELECT pg_proaudit_set_rule(null, 'disconnect', null, null, current_user);

create database " D B 1";
SELECT pg_proaudit_set_rule(' D B 1', 'authenticate', null, null, null);

create database " D b 2";
\c " D b 2"
create extension pg_proaudit;
SELECT pg_proaudit_set_rule(current_database(), 'disconnect', null, null, null);
```

F.48.4. pg_proaudit_settings View

This view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet. The `pg_proaudit_settings` view consists of the following columns:

- *db_name* (`text`) — name of the database for which to log security events.
- *event_type* (`text`) — event type to log.
- *object_type* (`text`) — type of the object for which security events are to be logged.
- *object_name* (`text`) — name of the object for which security events are to be logged.
- *role_name* (`text`) — the role on behalf of which logged actions are performed.
- *comment* (`text`) — comment to describe the created logging rule.

F.48.5. Security Events

You can configure the `pg_proaudit` extension to log classes of security events and specific events by specifying the respective value in the *event_type* argument of the pg_proaudit_set_rule() function.

The following classes of security events are supported:

- `ALL_DDL`: `CREATE`, `ALTER`, `DROP` for any database object except stored procedures and functions.
- `ALL_DDL_NONTEMP`: same as `ALL_DDL` but the scope is limited to the objects that are not contained in `pg_temp_`*nnn* temporary schemas.
- `ALL_DML`: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE` for any table type; `EXECUTE` for functions and stored procedures.
- `ALL_DML_NONTEMP`: same as `ALL_DML` but the scope is limited to the objects that are not contained in `pg_temp_`*nnn* temporary schemas.
- `ALL_MOD`: `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE` for any table type.
- `ALL_PROC`: `CREATE`, `ALTER`, `DROP` for any function and stored procedure.
- `ALL_ROLE`: `CREATE`, `ALTER`, `DROP` for `USER`, `ROLE`, `GROUP`, `PROFILE`, as well as execution of the `GRANT` command.

The following specific security events are supported:

- AUTHENTICATE
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES

- ALTER DOMAIN
- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER PROFILE
- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER MAPPING
- ALTER VIEW
- CLUSTER
- COMMENT
- COPY
- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EVENT TRIGGER
- CREATE EXTENSION
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY
- CREATE POLICY
- CREATE PROFILE
- CREATE ROLE, CREATE USER, CREATE GROUP
- CREATE RULE
- CREATE SCHEMA

- CREATE SEQUENCE
- CREATE SERVER
- CREATE TABLE, CREATE TABLE AS, SELECT INTO
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TRANSFORM
- CREATE TRIGGER
- CREATE TYPE
- CREATE USER MAPPING
- CREATE VIEW
- DEALLOCATE
- DELETE
- DO
- DROP ACCESS METHOD
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EVENT TRIGGER
- DROP EXTENSION
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION
- DROP INDEX
- DROP LANGUAGE
- DROP MATERIALIZED VIEW
- DROP OPERATOR
- DROP OPERATOR CLASS
- DROP OPERATOR FAMILY
- DROP OWNED
- DROP POLICY
- DROP PROFILE
- DROP ROLE, DROP USER, DROP GROUP
- DROP RULE
- DROP SCHEMA
- DROP SEQUENCE
- DROP SERVER
- DROP TABLE
- DROP TABLESPACE
- DROP TEXT SEARCH CONFIGURATION
- DROP TEXT SEARCH DICTIONARY
- DROP TEXT SEARCH PARSER
- DROP TEXT SEARCH TEMPLATE
- DROP TRANSFORM
- DROP TRIGGER
- DROP TYPE
- DROP USER MAPPING
- DROP VIEW
- EXECUTE
- GRANT
- INSERT
- PREPARE
- REASSIGN OWNED

- REFRESH MATERIALIZED VIEW
- REINDEX
- RESET
- REVOKE
- SECURITY LABEL
- SELECT
- SET
- UPDATE
- TRUNCATE TABLE

F.48.6. Security Event Log Configuration Parameters

The pg_proaudit extension provides several configuration parameters for managing security event log files. These parameters can be set in the postgresql.conf configuration file, or with the help of the ALTER SYSTEM command. For the changes to take effect, call the pg_reload_conf() function or restart the database server. For additional configuration, the syslog_ident and syslog_facility configuration parameters can be used.

pg_proaudit.log_destination (string)

Defines the method for logging security events. Possible values are:

- csvlog — log security events in a CSV file.
- syslog — log security events in syslog.

You can specify one or more values separated by commas.

Default: csvlog

pg_proaudit.log_catalog_access (boolean)

Specifies whether to log access to system catalog objects in the pg_catalog schema.

When set to off, no events will be logged, even if there are rules for the CATALOG RELATION, CATALOG FUNCTION, or ALL object types.

It is not recommended to set the parameter to on, if you do not plan to log events for system catalog objects. Doing otherwise may impact Postgres Pro performance, even if there are no rules for the aforementioned object types.

Default: off

pg_proaudit.log_command_text (boolean)

Specifies whether to log the SQL command text for security events.

Default: on

pg_proaudit.log_directory (string)

Specifies the path to the directory that stores CSV log files. This can be an absolute path, or a relative path to the cluster data directory (PGDATA). This parameter is used if pg_proaudit.log_destination contains the csvlog value.

Default: pg_proaudit

pg_proaudit.log_filename (string)

Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the strftime specification of the Open Group (*http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html*). This parameter is used if pg_proaudit.log_destination contains the csvlog value.

Default: `postgresql-%Y-%m-%d_%H%M%S.log`

`pg_proaudit.log_rotation_size` (`integer`)

Sets the maximum size of the CSV log file, in kilobytes. When this size is achieved, `pg_proaudit` creates a new file for logging security events. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog`. If set to 0, disables size-based creation of new log files.

Default: 10MB

`pg_proaudit.log_rotation_age` (`integer`)

Sets the maximum lifetime of a log file, in minutes. After this timeframe has elapsed, `pg_proaudit` creates a new file for logging security events. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value. If set to 0, disables time-based creation of new log files.

Default: 1 day

`pg_proaudit.log_truncate_on_rotation` (`boolean`)

Specifies whether to truncate log files when logging is switched to an existing log file. If set to `off`, `pg_proaudit` appends new log entries to the end of the file. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value.

Default: `off`

`pg_proaudit.max_rules_count` (`integer`)

Specifies the maximum number of rules allowed. For the parameter changes to take effect, the database server must be restarted.

Default: 500

F.48.7. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the `file_fdw` extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the `file_fdw` and create an external server:

```
CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the `pg_proaudit.log_directory` and `pg_proaudit.log_filename` parameters.

```
CREATE FOREIGN TABLE pg_proaudit_log
      ( log_time timestamp(3) with time zone,
        current_usr_name text,
        database_name text,
        session_pid text,
        error_severity text,
        session_line_num bigint,
        session_line_subcommand_num bigint,
        event_type text,
        object_type text,
        object_name text,
        status text,
        error_message text,
        query_text text,
```

```
            query_args text,
            session_usr_name text,
            uuid text,
            xid text,
            vxid text )

   SERVER pg_proauditlog
   OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv' );
```

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

F.48.8. Examples

As an example, let's set up logging for the following security events:

- authentications/disconnections to the `postgres` database
- all actions of the user if at least one of the user session attributes, `session_user` or `current_user`, is either explicitly set to the `postgres` role, or is directly or indirectly a member of this role
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In psql, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

```
SHOW shared_preload_libraries;
 shared_preload_libraries
--------------------------
 pg_proaudit

\dx pg_proaudit
                   List of installed extensions
    Name     | Version | Schema |           Description
-------------+---------+--------+---------------------------------
 pg_proaudit | 2.0     | public | provides auditing functionality
```

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'
pg_proaudit.log_directory = 'audit'
pg_proaudit.log_filename = 'audit-%u.csv'
pg_proaudit.log_rotation_age = 1440
pg_proaudit.log_rotation_size = 0
pg_proaudit.log_truncate_on_rotation = on
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;
SHOW pg_proaudit.log_directory;
SHOW pg_proaudit.log_filename;
SHOW pg_proaudit.log_rotation_age;
SHOW pg_proaudit.log_rotation_size;
SHOW pg_proaudit.log_truncate_on_rotation;
SHOW pg_proaudit.log_command_text;
```

Suppose your PGDATA environment variable points to the cluster data directory. Since the pg_proaudit.log_directory defines a relative path to the log files, they will be located in the $PGDATA/audit directory. Let's create an empty file for each day of the week and make them available to their owner only:

```
touch $PGDATA/audit/audit-1.csv
touch $PGDATA/audit/audit-2.csv
touch $PGDATA/audit/audit-3.csv
touch $PGDATA/audit/audit-4.csv
touch $PGDATA/audit/audit-5.csv
touch $PGDATA/audit/audit-6.csv
touch $PGDATA/audit/audit-7.csv
chmod 600 $PGDATA/audit/audit-*.csv
```

Create a table for reading log entries:

```
CREATE TABLE pg_proaudit_log (
  log_time timestamp(3) with time zone,
  current_usr_name text,
  database_name text,
  session_pid text,
  error_severity text,
  session_line_num bigint,
  session_line_subcommand_num bigint,
  event_type text,
  object_type text,
  object_name text,
  status text,
  error_message text,
  query_text text,
  query_args text,
  session_usr_name text,
  uuid text,
  xid text,
  vxid text
);
```

Install the file_fdw extension and create an external server:

```
CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

Now let's create seven child foreign tables for the pg_proaudit_log table, for each day of the week:

```
CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-1.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-2.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-3.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-4.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-5.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
```

```
   OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv',  FORMAT 'csv');
```

To set up logging for the required security events, connect to the `postgres` database and execute the following commands:

```
SELECT pg_proaudit_set_rule (current_database(), 'AUTHENTICATE', null, null, null, 'Any
 authentication in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'DISCONNECT', null, null, null, 'Any
 disconnect from the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', 'TABLE', null, null, 'Any
 operations with any table in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, null, 'postgres', 'Any
 operation by "postgres" user in the current DB');
```

Create the `app_table` table and enable logging for all operations on this table:

```
CREATE TABLE app_table (id int, name text);
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, 'public.app_table',
 null);
```

Check that event logging is configured as expected:

```
SELECT * FROM pg_proaudit_settings;
 db_name  |  event_type  | object_type |   object_name    | role_name |
      comment
----------+--------------+-------------+------------------+-----------
+-------------------------------------------------
 postgres | authenticate | ALL         |                  |           | Any
 authentication in the current DB
 postgres | disconnect   | ALL         |                  |           | Any disconnect
 from the current DB
 postgres | ALL          | table       |                  |           | Any operations
 with any table in the current DB
 postgres | ALL          | ALL         |                  | postgres  | Any operation
 by "postgres" user in the current DB
 postgres | ALL          | ALL         | public.app_table |           |
(5 rows)
```

Save these logging rules into the `pg_proaudit.conf` file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the `app_table` table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the `app_table` table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, current_usr_name,
      session_pid, event_type, query_text, session_usr_name
FROM pg_proaudit_log
WHERE object_name = 'public.app_table';
       when        | current_usr_name | session_pid |  event_type  |
 query_text                  | session_usr_name
-------------------+------------------+-------------+--------------
+-----------------------------------------+------------------
 27.09.23 12:44:27 | postgres         | 2010        | CREATE TABLE | CREATE TABLE
 app_table (id int, name text); | postgres
```

```
 27.09.23 12:45:55 | postgres         | 2010        | INSERT       | INSERT INTO
 app_table VALUES (1, 'first');  | postgres
 27.09.23 12:46:00 | postgres         | 2010        | SELECT       | SELECT * FROM
 app_table;                    | postgres
(3 rows)
```

We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the `pg_proaudit_log` table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the `pg_proaudit_log` table and grant read rights to such views using built-in Postgres Pro access control methods.

F.49. pgpro_bindump — a replication protocol module for backup and restore

pgpro_bindump is a module designed to implement additional commands for the Postgres Pro replication protocol, specifically for use with the *pg_probackup3* utility. pgpro_bindump offers the following benefits:

- Simplified communication: pgpro_bindump does not require the SSH protocol and associated configurations to connect to a database server.
- Integrated WAL transfer: WAL files are transferred together with data files, reducing the risk of data loss during backups.
- Optimized storage: Files are not copied as they are, but are archived using the pg_probackup3 own format, `CBOR` (RFC 8949 Concise Binary Object Representation), which enhances the storage efficiency.

F.49.1. Architecture

A dedicated backend process is created to handle connections from external applications. You can use the pg_probackup3 utility or a custom application to send requests to this backend.

Multiple connections can be established for the same application if needed.

Since the pgpro_bindump module has direct access to the database files, it does not require any additional permissions.

pgpro_bindump uses the *libpgprobackup*, along with its built-in encoder module, to send data to the application.

The `walsender_plugin_libraries` plugin has been added to simplify the process of adding and utilizing new replication commands, including custom ones.

F.49.2. Limitations and Requirements

pgpro_bindump currently has the following limitations and requirements:

- `libpgprobackup.so` and `libpb3_encoder.so` are required for pgpro_bindump operation.

F.49.3. Installation and Setup

Once you complete Postgres Pro installation, follow the steps below.

1. Specify the following parameters in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_bindump'
wal_level = 'replica' # or 'logical'
walsender_plugin_libraries = 'pgpro_bindump'
```

2. Restart the Postgres Pro instance.

F.49.4. Replication Commands

The pgpro_bindump module implements the following replication commands:

- `just-noop` — a do-nothing command.
- `start_backup` — starts the backup process.
- `copy_files` — copies files in the `CBOR` format.
- `stop_backup` — stops the backup process.

The backup process runs in the PRO mode — an advanced data source mode that incorporates all available optimizations and enhancements, including the proprietary replication protocol and specialized replication commands.

To send commands from a user application to pgpro_bindump and to receive the output data from pgpro_bindump by the application, use libpq.

> **Note**
>
> An established connection to a running Postgres Pro server is required.

F.49.4.1. start_backup

```
start_backup LABEL label, INCR_MODE incr_mode, START_LSN start_lsn,
 TRANSFER_MODE transfer_mode,
[TRANSFER_BUFFER_SIZE buffer_size]
```

Starts the backup process. Sends the following data to the application:

- `start_lsn` — LSN at the start of the backup.
- `start_tli` — the timeline ID at the start of the backup.
- `min_xid` — the minimal transaction ID at the start of the backup.
- `min_multixact` — the minimal `multixact` ID at the start of the backup.
- `tablespace_list` — a list of tablespaces included in the backup.
- `database_list` — a list of databases included in the backup.

`LABEL` *label*

The name of the backup.

`INCR_MODE` *incr_mode*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

`START_LSN` *start_lsn*

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_MODE` *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`TRANSFER_BUFFER_SIZE` *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

F.49.4.2. copy_files

```
copy_files VERIFY_CHECKSUMS [TRUE | FALSE], COMPRESS_ALG compress_alg,
 COMPRESS_LVL compress_lvl, TRANSFER_MODE transfer_mode,
[INCR_MODE incr_mode], [START_LSN start_lsn], [TRANSFER_BUFFER_SIZE buffer_size],
[WORKER_INFO number_of_workers:worker_id]
```

Forwards blocks of data files and WAL files packaged in the `CBOR` format.

`VERIFY_CHECKSUMS`

A boolean value (`true` or `false`) indicating whether to verify checksums.

`COMPRESS_ALG` *`compress_alg`*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

`COMPRESS_LVL` *`compress_lvl`*

The compression level. Possible values: 1, 2, 3, 4, 5.

`TRANSFER_MODE` *`transfer_mode`*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`INCR_MODE` *`incr_mode`*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

`START_LSN` *`start_lsn`*

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_BUFFER_SIZE` *`buffer_size`*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

`WORKER_INFO` *`number_of_workers`*`:`*`worker_id`*

The number of workers and the worker ID.

F.49.4.3. stop_backup

```
stop_backup STREAM [TRUE | FALSE], COMPRESS_ALG compress_alg,
 COMPRESS_LVL compress_lvl,
[EXTERNALS externals] [TRANSFER_BUFFER_SIZE buffer_size], [TRANSFER_MODE transfer_mode]
```

Completes the copy process and closes the existing connection. Sends the following data to the application:

- `stop_lsn` — LSN at the end of the backup.
- `stop_tli` — the timeline ID at the end of the backup.
- The `backup.control` file.
- A set of WAL files (only if WAL streaming is enabled).

`STREAM`

A boolean value (`true` or `false`) indicating whether WAL streaming is enabled.

`COMPRESS_ALG` *`compress_alg`*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

`COMPRESS_LVL` *`compress_lvl`*

The compression level. Possible values: 1, 2, 3, 4, 5.

`EXTERNALS` *`externals`*

A list of external directories.

`TRANSFER_BUFFER_SIZE` *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

`TRANSFER_MODE` *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

Postgres Professional, Moscow, Russia.

F.50. pg_prewarm — preload relation data into buffer caches

The pg_prewarm module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the pg_prewarm function, or can be performed automatically by including pg_prewarm in shared_preload_libraries. In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called autoprewarm.blocks and will, using 2 background workers, reload those same blocks after a restart.

F.50.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
           first_block int8 default null,
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually main. The fourth argument is the first block number to prewarm (NULL is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (NULL means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. prefetch issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. read reads the requested range of blocks; unlike prefetch, this is synchronous and supported on all platforms and builds, but may be slower. buffer reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using prefetch or read, or by Postgres Pro when using buffer — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update autoprewarm.blocks immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to autoprewarm.blocks.

F.50.2. Configuration Parameters

pg_prewarm.autoprewarm (boolean)

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

pg_prewarm.autoprewarm_interval (integer)

This is the interval between updates to autoprewarm.blocks. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
```

```
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
pg_prewarm.autoprewarm_interval = 300s
```

Robert Haas <rhaas@postgresql.org>

F.51. pgpro_rp — resource prioritization

pgpro_rp is a Postgres Pro Enterprise extension for resource prioritization.

On systems with limited resources or under heavy load, you may need to prioritize transaction execution, so that some transactions are executed more quickly than the others. For example, you may want to execute simple user queries as fast as possible, even if it delays less urgent tasks, such as complex OLAP queries that may be running at the same time. Postgres Pro Enterprise enables you to assign a *resource prioritization plan* to a particular session, which can slow it down based on the amount of CPU, I/O read, and I/O write resources this session consumes as compared to other sessions. These parameters can take weight values `1`, `2`, `4`, and `8`. The higher the value, the more resources the session can use. By default, all sessions have weight `4` for all types of resources. The resource prioritization plan contains a set of these prioritization parameters as a `jsonb` and can be assigned to any user or role.

The plan is selected during session creation using a login event trigger as follows:

- First, pgpro_rp calls the plan selection function if it has been set. Otherwise, it searches for a plan assigned to the current user.
- If no plan is assigned to the user, pgpro_rp selects the plan with the maximum sum of priorities from the plans assigned to the roles that the user is a member of.
- Finally, the priority settings of the found plan are applied.

If the plan cannot be determined, the default priority settings are applied: all priorities have the value of `4`.

> **Note**
>
> Only superusers can manage and update plans.

F.51.1. Installation

The pgpro_rp extension is a built-in extension included into Postgres Pro Enterprise, but since pgpro_rp uses shared memory for caching user prioritization parameters, it has to be installed separately. Once you have `pgpro_rp` installed, complete the following steps to enable `pgpro_rp`:

1. Add `pgpro_rp` to the shared_preload_libraries parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_rp'
```

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.
3. Create the `pgpro_rp` extension:

```
CREATE EXTENSION pgpro_rp;
```

F.51.2. Usage

pgpro_rp extension supports the following operation modes:

- Permanent plan mode
- Changeable plan mode

F.51.2.1. Permanent Plan Mode

This operation mode is used to set up permanent resource prioritization plans for users or roles. These plans remain unchanged regardless of the time of the day, the day of the week, etc. You don't have to create and set up plan assignment groups for users or roles. In other words, only the preinstalled default group is used implicitly.

This mode includes the following steps:

- Create a set of resource prioritization plans using pgpro_rp_create_plan.
- Assign created plans to users or roles using pgpro_rp_create_role_plan.

The created plans can be updated or deleted if needed.

Example:

```
-- Create resource prioritization plans
SELECT pgpro_rp_create_plan('plan_2_2_2', 2, 2, 2);
SELECT pgpro_rp_create_plan('plan_8_8_8', '{ "session_cpu_weight":8,
"session_ioread_weight":8, "session_iowrite_weight":8}');

-- Assign plans to roles
SELECT pgpro_rp_create_role_plan('users', 'plan_2_2_2');
SELECT pgpro_rp_create_role_plan('admins', 'plan_8_8_8');
```

F.51.2.2. Changeable Plan Mode

This operation mode is used to set up various resource prioritization plans for users or roles that are subject to changing in accordance with the time of the day, the day of the week, etc.

This mode includes the following steps:

- Create a set of resource prioritization plans using pgpro_rp_create_plan.
- Create several plan assignment groups for users or roles using pgpro_rp_create_group.
- Add plans to plan assignment groups using pgpro_rp_create_group_role_plan.
- Set an active group when necessary using pgpro_rp_set_active_group.

Example:

```
-- Create resource prioritization plans
SELECT pgpro_rp_create_plan('plan_8_8_8', 8, 8, 8);
SELECT pgpro_rp_create_plan('plan_4_4_4', 4, 4, 4);
SELECT pgpro_rp_create_plan('plan_2_2_2', 2, 2, 2);
SELECT pgpro_rp_create_plan('plan_1_1_1', 1, 1, 1);

-- Create plan assignment groups to users or roles and add in plan assignment
 groups
SELECT pgpro_rp_create_group('day_plan');
SELECT pgpro_rp_create_group_role_plan('day_plan', 'top', 'plan_4_4_4');
SELECT pgpro_rp_create_group_role_plan('day_plan', 'main', 'plan_2_2_2');
SELECT pgpro_rp_create_group_role_plan('day_plan', 'hr', 'plan_1_1_1');

SELECT pgpro_rp_create_group('night_plan');
SELECT pgpro_rp_create_group_role_plan('night_plan', 'top', 'plan_8_8_8');
SELECT pgpro_rp_create_group_role_plan('night_plan', 'main', 'plan_1_1_1');
SELECT pgpro_rp_create_group_role_plan('night_plan', 'hr', 'plan_2_2_2');

-- Set an active group
CALL pgpro_rp_set_active_group('day_plan');
```

F.51.3. The pgpro_rp_roles_plans_view View

All plan assignment groups along with the roles that are included in them, and the plans assigned to the roles are available via a view named pgpro_rp_roles_plans_view. This view contains one row for each role with an assigned plan. The columns of the view are shown in Table F.34.

Table F.34. `pgpro_rp_roles_plans_view` Columns

Name	Type	Description
group_name	text	The name of the group
rolname	text	The name of the user/role
plan_name	text	The plan used for the user/role

F.51.4. Functions

F.51.4.1. Plan Management Functions

The functions described in this section provide the ability to create, modify, or delete a resource prioritization plan.

`pgpro_rp_create_plan(a_plan_name text, a_plan_options jsonb) returns bigint`
`pgpro_rp_create_plan(a_plan_name text, a_cpu_weight int, a_ioread_weight int, a_iowrite_weight int) returns bigint`

Creates a plan with the given name and options or prioritization parameters and returns the ID of the created plan. Superuser privileges are required to call this function.

`pgpro_rp_rename_plan(a_plan_name_old text, a_plan_name_new text) returns void`

Renames the specified plan. Superuser privileges are required to call this function.

`pgpro_rp_update_plan(a_plan_name text, a_plan_options jsonb) returns void`

Modifies the options of the specified plan. Superuser privileges are required to call this function.

`pgpro_rp_delete_plan(a_plan_name text) returns void`

Deletes the specified plan. Superuser privileges are required to call this function.

`pgpro_rp_get_plan_id_by_name(a_plan_name text) returns bigint`

Returns the ID of the created plan by the plan name.

F.51.4.2. Plan Assignment Group Functions

The functions described in this section provide the ability to manage plan assignment groups for users or roles.

`pgpro_rp_create_group(a_group_name text) returns bigint`

Creates a plan assignment group and returns the ID of the created group. Superuser privileges are required to call this function.

`pgpro_rp_rename_group(a_group_name text, a_new_group_name text) returns void`

Renames the specified group. Superuser privileges are required to call this function.

`pgpro_rp_delete_group(a_group_name text) returns void`

Deletes the specified group. Superuser privileges are required to call this function.

F.51.4.3. Plan Assignment Functions

The functions described in this section provide the ability to manage plan assignment for roles.

The following functions work with an active plan assignment group specified in the `pgpro_rp_options` table:

`pgpro_rp_create_role_plan(a_role_name text, a_plan_name text) returns void`

Assigns the default plan to the specified role. Superuser privileges are required to call this function.

`pgpro_rp_update_role_plan(a_role_name text, a_plan_name text) returns void`

Changes the default plan for the specified role. Superuser privileges are required to call this function.

`pgpro_rp_delete_role_plan(a_role_name text) returns void`

Deletes the plan assigned to the specified role. Superuser privileges are required to call this function.

Functions to add/delete in plan assignment groups for users or roles:

`pgpro_rp_create_group_role_plan(a_group_name text, a_role_name text, a_plan_name text) returns void`

Adds the specified plan to the specified group. Superuser privileges are required to call this function.

`pgpro_rp_delete_group_role_plan(a_group_name text, a_role_name text) returns void`

Deletes the specified plan from the specified group. Superuser privileges are required to call this function.

Other functions:

`pgpro_rp_cleanup_roles_plans() returns void`

Deletes the plans assigned to the non-existent roles from the `pgpro_rp_roles_plans` table. Superuser privileges are required to call this function.

`pgpro_rp_set_active_group(a_group_name text) returns void`

Makes the specified plan assignment group active and clears the prioritization parameter cache. Superuser privileges are required to call this function.

`pgpro_rp_get_active_group() returns text`

Returns the ID of the active group.

F.51.4.4. Plan Selection Functions

You can declare a custom function to select resource prioritization plans, which takes no arguments and returns the plan ID, to be called at the session start using the functions described below.

`pgpro_rp_set_plan_selection_function(a_func_name text) returns void`

Sets the plan selection function. If `NULL` is passed, the current function is reset. Superuser privileges are required to call this function.

`pgpro_rp_get_plan_selection_function() returns text`

Returns the current plan selection function.

F.51.4.5. Backend Plan Function

`pgpro_rp_backend_set_plan(a_pid int, a_plan_name text) returns void`

Searches for a plan with the given name and applies its settings to the backend with the specified PID. Superuser privileges are required to call this function.

F.51.4.6. Cache Functions

When creating any session, the prioritization parameter values from the assigned plan are applied to this session. However, searching for a plan requires certain resources (you need to read data from several tables), so the values of user prioritization parameters are cached in shared memory. If you create another session, its user will be searched in the cache, and if the user is found, the values of the prioritization parameters stored in the cache will be applied to the newly created session. Since the values in the cache may expire, the following function is provided to clear the cache:

`pgpro_rp_invalidate_cache() returns void`

Clears the cache of prioritization parameters in shared memory. Superuser privileges are required to call this function.

This function should be called in cases where user prioritization settings may change (assigning roles to users, changing the parameters of the active group/plans in use, etc.).

F.51.5. Configuration Parameters

If necessary, you can also manage priorities manually:

- Configure the time interval for collecting usage statistics for all active backends by setting the usage_tracking_interval parameter in the `postgresql.conf`. Avoid setting `usage_tracking_interval` to small values as frequent statistics collection can cause overhead.
- Depending on the resources you need to control, modify one or more of the following parameters for the sessions you would like to prioritize:
  - session_cpu_weight — CPU usage.
  - session_ioread_weight — I/O read throughput.
  - session_iowrite_weight — I/O write throughput.

  Sessions with the same weight have the same priority for resource usage, so if equal weights are assigned to all sessions, performance is not affected, regardless of the weight value.

  For all possible ways of modifying configuration for a particular session, see Section 19.1.

F.51.6. Example

The following example demonstrates using pgpro-rp.

```
CREATE EXTENSION pgpro_rp;
CREATE USER test_user;
SELECT pgpro_rp_create_plan(
 'test_plan',
 '{ "session_cpu_weight":8, "session_ioread_weight":8, "session_iowrite_weight":8 }'
);
SELECT pgpro_rp_create_role_plan('test_user', 'test_plan');
```

The next time that the `test_user` user logs in, the prioritization parameters will look as follows:

```
SHOW session_cpu_weight;
 session_cpu_weight
--------------------
 8
(1 row)
SHOW session_ioread_weight;
 session_ioread_weight
-----------------------
 8
(1 row)
SHOW session_iowrite_weight;
 session_iowrite_weight
------------------------
 8
(1 row)
```

F.52. pgpro_scheduler — scheduling, monitoring and managing job execution

pgpro_scheduler is a built-in Postgres Pro Enterprise extension for scheduling, monitoring, and managing job execution within the Postgres Pro Enterprise database. With pgpro_scheduler, you can:

- Set advanced schedules using jsonb objects or crontab strings.
- Dynamically calculate the next execution time for repeated jobs.
- Execute SQL commands of the job in a single transaction or in sequential transactions, if required.
- Submit jobs for immediate or delayed one-time execution in parallel with the scheduled jobs.

Unlike external scheduling daemons, pgpro_scheduler offers the following benefits:

- Any user can schedule jobs independently.
- Job scheduling can be managed on the fly without restarting the database.
- Scheduling is very lightweight since pgpro_scheduler uses background workers to schedule, monitor, and manage job execution. At the same time, pgpro_scheduler does not require any client connections for scheduling.
- For enhanced stability, each database has its own supervisor scheduler, with each scheduled job executed by a separate background worker.

> **Note**
>
> pgpro_scheduler waits in the suspended state on a standby server to be started when the standby is promoted to a primary server.

> **Note**
>
> Note that for all the executed jobs, the pg_stat_activity view will still show the name of the database superuser, which is used by the background worker.

F.52.1. Installation and Setup

The pgpro_scheduler extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable pgpro_scheduler:

1. Add pgpro_scheduler to the shared_preload_libraries parameter in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pgpro_scheduler'
   ```

2. Create the pgpro_scheduler extension using the following query:

   ```
   CREATE EXTENSION pgpro_scheduler;
   ```

   Make sure to create the pgpro_scheduler extension for each database you are planning to use.

Once you complete the installation and setup, configure pgpro_scheduler for your database.

F.52.2. Configuration

You must have superuser rights to configure pgpro_scheduler.

To configure pgpro_scheduler, modify the following settings in the postgresql.conf file:

1. Specify the names of the databases for which you need to schedule jobs, in the comma-separated format:

   ```
   schedule.database = 'database1,database2'
   ```

2. To control the workload in your system, set the maximum number of background workers that can run simultaneously on each database:

   ```
   schedule.max_workers = 5
   ```

3. Optionally, set the number of background workers available for one-time job execution:

   ```
   schedule.max_parallel_workers = 3
   ```

   By default, two background workers for one-time jobs are available. These workers are not included into the `schedule.max_workers` number. Thus, one-time jobs can run in parallel with the scheduled jobs even if all the `schedule.max_workers` workers are busy.

4. Run `pg_reload_conf()` for the changes to take effect:

   ```
   SELECT pg_reload_conf();
   ```

> **Important**
>
> When setting the `schedule.max_workers` variable, make sure to leave enough workers for the rest of the system as other subsystems may also use background workers. The `schedule.max_workers` value cannot exceed the total number of workers enabled by the `max_worker_processes` Postgres Pro variable.
>
> The `pgpro_scheduler` extension starts a separate background worker for the system, each database, and each executed job. For example, if you work with two databases and set the maximum number of workers and parallel workers to 5 and 3, respectively, `pgpro_scheduler` can use up to 19 workers at peak times: one worker is supervising the system, two workers are monitoring the two databases, and each database uses five workers for job scheduling and three workers for running one-time jobs. If all background workers are busy, the jobs will wait for the next available worker. Scheduled and one-time jobs have separate job queues.
>
> If required, you can later change the number of workers. The running jobs will not be affected.

You can also dynamically configure `pgpro_scheduler` from the command line. In this case, you can set different number of workers for different databases:

```
ALTER SYSTEM SET schedule.database = 'database1,database2';
ALTER DATABASE database1 SET schedule.max_workers = 5;
ALTER DATABASE database2 SET schedule.max_workers = 3;
ALTER SYSTEM SET schedule.max_parallel_workers = 3;
SELECT pg_reload_conf();
```

Once `pgpro_scheduler` is configured, enable it on your system, as follows:

```
SELECT schedule.enable();
```

If this function returns `true`, `pgpro_scheduler` is ready to use, and you can start scheduling jobs as explained in Section F.52.3.1 and Section F.52.3.2.

> **Note**
>
> If you restart the server, `pgpro_scheduler` is not automatically restarted by default. To change this behavior, you can set the schedule.auto_enabled parameter to `on`.

See Also

Section F.52.4.1

F.52.3. Usage

F.52.3.1. Creating Scheduled Jobs

To create and schedule a job, run the `create_job()` function that takes scheduling options as a `jsonb` object:

```
schedule.create_job(options jsonb)
```

In the `jsonb` object, you must specify one or more SQL commands in the `commands` key, and set the job schedule with at least one of the following keys:

- `dates` — a single date or an array of dates, in the `timestamp with time zone` format
- `cron` — a string, in the `crontab` format. A traditional five-field `crontab` format is used. The first field stands for minute, the second — for hour, the third — for day of the month, the fourth — for month, and the fifth — for day of the week.

  ```
  ┌── minute (0 - 59)
  │ ┌──── hour (0 - 23)
  │ │ ┌──── day of the month (1 - 31)
  │ │ │ ┌────── month (1 - 12)
  │ │ │ │ ┌────── day of the week (0 - 6) (Sunday to Saturday)
  │ │ │ │ │
  * * * * *
  ```

  A six-field `crontab` format can be used alongside the traditional five-field format. In this case the first field stands for second. When you use the six-field format and do not want to specify a second you have to put 0 in the first field.

  Alternatively, the following keywords can be used instead of a `crontab` string to specify when the job will be started:

  - `@every_second` — each second
  - `@hourly` — at the beginning of each hour
  - `@daily` — at the beginning of each day
  - `@midnight` — at the beginning of each day
  - `@weekly` — at the beginning of each week
  - `@monthly` — at the beginning of each month
  - `@yearly` — at the beginning of each year
  - `@annually` — at the beginning of each year
- `rule` — a `jsonb` object that includes one or more of the following keys:
  - `seconds` — seconds; an array of integers in range [0, 59]
  - `minutes` — minutes; an array of integers in range [0, 59]
  - `hours` — hours; an array of integers in range [0, 23]
  - `days` — days of the month; an array of integers in range [1, 31]
  - `months` — months; an array of integers in range [1, 12]
  - `wdays` — days of the week; an array of integers in range [0, 6], where 0 is Sunday.
  - `onstart` — integer value 0 or 1. If `onstart` is set to 1, the job is executed only once when `pg-pro_scheduler` is started.

You can combine `dates`, `cron`, and `rule` scheduling keys for advanced use cases.

As a result, `pgpro_scheduler` creates an active job with the specified schedule and returns the job ID.

> **Tip**
>
> For simple job schedules, you can use the following shortcut syntax:
>
> `schedule.create_job(`*`cron`*`, `*`commands`*`)`
> `schedule.create_job(`*`dates`*`, `*`commands`*`)`
>
> For details, see schedule.create_job() function description.

If required, you can later modify one or more scheduling options with the `set_job_attribute()` or `set_job_attributes()` functions, respectively.

If all background workers are busy at the specified time, the job waits for the next available worker. By default, the job can wait forever. You can limit the maximum wait time by setting the `last_start_available` key, in the time interval format. If the timeout is reached, `pgpro_scheduler` cancels the job execution.

Examples:

To run the job every day at 3pm, and, additionally, on December 31, 2017 at 7pm , and on April 4, 2020 at 1pm:

```
SELECT schedule.create_job('{"commands": "SELECT 15", "cron": "0 15 * * *", "dates":
 [ "2017-12-31 19:00", "2020-04-04 13:00" ]}');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{"commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
 *", "last_start_available": "30 seconds" }');
```

> **Note**
>
> Both for scheduled and one-time jobs, you cannot manage their main transactions, namely using `COMMIT` and `ROLLBACK`. However, you can create and manage autonomous transactions.

F.52.3.1.1. Specifying the Time Window for Job Execution

In addition to the general schedule, you can specify the timeframe during which the scheduled job can be executed. To ensure that `pgpro_scheduler` only executes the job within the specified time window, define the `start_date` and `end_date` keys, in the `timestamp with time zone` format. You can set one of these keys only to limit the start or the end time, respectively. If you define a time window for the job, `pgpro_scheduler` will only schedule this job within this time window. If the started job is incomplete when the specified time window ends, `pgpro_scheduler` completes the job and then excludes the job from further scheduling.

Examples:

To start scheduling the job only after 11am on May 1, 2017:

```
SELECT schedule.create_job('{"commands": "SELECT now()", "cron": "2 17 * * *",
 "start_date": "2017-05-01 11:00" }');
```

To schedule the job in the timeframe from 11am on May 1 to 3pm on June 4, 2017:

```
SELECT schedule.create_job('{"commands": "SELECT now()", "cron": "2 17 * * *",
 "start_date": "2017-05-01 11:00", "end_date": "2017-06-04 15:00" }');
```

F.52.3.1.2. Running SQL Commands in Separate Transactions

The `commands` key can have values of text and array types. If you specify several SQL commands as text separated by semicolons, the whole job is executed in a single transaction. If it is critical to perform each SQL command in a separate transaction, pass the SQL commands as an array. You can modify this behavior by setting the `use_same_transaction` key to `true`. In this case, SQL commands in the array are executed in a single transaction.

Examples:

To run the whole job in a single transaction:

```
SELECT schedule.create_job('{"commands": "SELECT 1; SELECT 2; SELECT 3;", "cron": "23
 23 */2 * *" }');
```

To run commands in separate transactions:

```
SELECT schedule.create_job('{"commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
 "cron": "23 23 */2 * *" }');
```

To run the whole job in a single transaction when passing the commands as an array:

```
SELECT schedule.create_job('{"commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
 "cron": "23 23 */2 * *", "use_same_transaction": true }');
```

F.52.3.1.3. Calculating the Next Start Time of the Scheduled Job

For repeated jobs, the next start time can be computed by an SQL statement specified in the `next_time_statement` key. In this case, the first job starts on schedule, while all the successive job runs occur at the computed times.

After the job run completes, `pgpro_scheduler` executes the SQL statement in the `next_time_statement` key to calculate the next start time and returns the result, in the `timestamp with time zone` type. If the return value is of a different type or an error occurs, `pgpro_scheduler` marks the job as broken and cancels any further execution. This process is repeated for each successive job run.

> **Tip**
>
> When the job run completes, `pgpro_scheduler` sets the transaction state in the `schedule.transaction_state` variable, in the `text` format. You can use this variable in your `next_time_statement` to dynamically calculate the next start time depending on the transaction state. At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values for the main transaction. Other values may indicate an internal `pgpro_scheduler` error.

Examples:

To run the job first at 10:45, and then in a day after the job completes:

```
SELECT schedule.create_job('{"commands": "SELECT random()", "cron": "45 10 * * *",
 "next_time_statement": "SELECT now() + ''1 day''::interval" }');
```

F.52.3.1.4. Setting Additional Conditions for Job Execution

The `pgpro_scheduler` extension enables you to define additional conditions for task execution:

- Set time limits for job execution with the `max_run_time` key. If the execution time is exceeded, `pgpro_scheduler` cancels the job.
- Define the maximum time a scheduled job can wait for execution using the `last_start_available` key. If the timeout is reached, `pgpro_scheduler` cancels the job.

- Schedule a job to be executed with the rights of another user by specifying the `run_as` key. You must have superuser rights to use this key.
- Define an SQL command to execute if the main command fails using the `onrollback` key.

Examples:

To limit job execution to 5 seconds:

```
SELECT schedule.create_job('{"commands": "SELECT pg_sleep(10)", "cron": "15 */10 * *
 *", "max_run_time": "5 seconds" }');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{"commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
 *", "last_start_available": "30 seconds" }');
```

To start the job with the rights of the `robot` user:

```
SELECT schedule.create_job('{"commands": "SELECT session_user", "cron": "5 */5 * * *",
 "run_as": "robot" }');
```

To define a fallback SQL command in case the main command fails:

```
SELECT schedule.create_job('{"commands": "SELECT ''zzz''", "cron": "55 */12 * * *",
 "onrollback": "SELECT ''Cannot select zzz''" }');
```

F.52.3.2. Submitting One-Time Jobs

You can submit jobs for one-time execution using the `schedule.submit_job()` function. Such jobs use a separate pool of background workers defined by the `schedule.max_parallel_workers` variable, and can run in parallel with the scheduled jobs. By default, two one-time jobs can run concurrently. If you submit more jobs, they will wait in the queue for the next available background worker.

To execute a one-time job immediately, pass SQL commands in the *`query`* argument. For example:

```
schedule.submit_job(query := 'select 1');
```

Instead of passing SQL query parameters directly, you can define numbered placeholders in the *`query`* argument, such as $1 and $2, and pass an array of parameters in the *`params`* argument, with each array element corresponding to a placeholder. For brevity, you can omit the *`query`* and *`params`* names:

```
schedule.submit_job(query := 'select $1, $2', params := '{"text 1", "text 2"}')
```

To start a one-time job at the specified time, use the *`run_after`* argument:

```
schedule.submit_job('select ''flowers''', run_after := '2017-03-08 08:00:01');
```

Alternatively, you can delay the job start until the specified jobs are complete using the *`depends_on`* argument. For example, to run a job after completing the jobs with 23, 15, and 334 IDs, run:

```
schedule.submit_job('select ''well done''', depends_on := '{23, 15, 334}')
```

If required, you can repeat the job execution by passing the `schedule.resubmit()` function as part of the *`query`* argument. For example:

```
schedule.submit_job('select 1, schedule.resubmit(run_after := ''5'')');
```

The *`run_after`* argument specifies the time interval before the job is restarted, in seconds. By default, the interval is 1 second.

The resubmitted job cannot be executed more than the number of times set in the *`resubmit_limit`* argument. If this limit is reached, the job receives the `done` status, with the corresponding error message.

If you want to cancel a resubmitted job, run:

```
schedule.cancel_job(job_id bigint);
```

To monitor one-time jobs, use the job_status and all_job_status pgpro_scheduler views.

For details on all the functions available for managing one-time jobs, see Section F.52.4.6.3.

F.52.3.3. Changing and Removing Scheduled Jobs

When you create a new job with the create_job() function, the job becomes active and waits for execution based on the specified schedule. Using the job ID returned by the create_job() function, you can change the scheduling settings or remove the job from the schedule. To change the specified schedule for the jobs, use set_job_attribute() or set_job_attributes() functions:

- To modify a single property of the job, run the set_job_attribute() function with the job ID, the property name to change, and the new value for this property.
- To modify more than one property of the job, run the set_job_attributes() function instead. In this case, you can specify all the job properties at once in a jsonb object. For details on all the keys available for job scheduling, see the create_job() function description.

To temporarily exclude the job from scheduling, run the deactivate_job() function:

```
schedule.deactivate_job(job_id integer)
```

You can re-activate the job later by running the activate_job() function:

```
schedule.activate_job(job_id integer)
```

To permanently remove the job from the schedule, run the drop_job() function:

```
schedule.drop_job(job_id integer)
```

F.52.3.4. Monitoring Scheduled Jobs

You must have superuser rights to monitor job execution for the whole system. Otherwise, you can only monitor the jobs that you own. To monitor scheduled jobs, pgpro_scheduler provides multiple functions that return cron_rec or cron_job records:

- get_job() — retrieves information about the job.
- get_owned_cron() — retrieves the list of jobs owned by user.
- get_cron() — retrieves the list of jobs executed by user.
- get_active_jobs() — returns the list of jobs executed at the moment of the function call.
- get_log() — returns the list of all completed jobs.
- get_user_log() — returns list of the completed jobs executed by the specified user.
- clean_log() — deletes all records with information about completed jobs.

To learn more about each function, see Section F.52.4.6.

F.52.3.5. Auditing Job Scheduling

pgpro_scheduler enables you to audit job scheduling to rule out human error if you observe unexpected changes in scheduled job execution.

By default, pgpro_scheduler does not store information on schedule changes. To enable this feature, set the schedule.enable_history parameter to true. Once this parameter is enabled, pgpro_scheduler stores schedule modifications in the schedule.cron__history table, and logs all deleted jobs in the schedule.cron__deleted table. Logged history is never deleted from these tables, so a superuser can review schedule changes introduced by all users at any time.

For details on logged information, see Section F.52.4.5.

F.52.3.6. Scheduling Jobs on a Multi-Master Cluster

Using pgpro_scheduler, you can manage scheduled and one-time jobs on a cluster configured with multimaster. pgpro_scheduler can only manage jobs on the node on which it is installed. Thus, you must install and enable pgpro_scheduler on all nodes on which you would like to schedule jobs. pgpro_scheduler instances will manage jobs on different nodes independently, but the executed jobs will be replicated to other nodes.

Even if you are planning to schedule jobs on a single node only, it is recommended to enable pgpro_scheduler on several nodes. In this case, if a node with scheduled jobs fails, another pgpro_scheduler instance picks up these jobs. If pgpro_scheduler is running on more than one node, the node with the smallest node ID is selected. The naming pattern of node IDs is defined by the schedule.nodename GUC variable.

F.52.4. Reference

F.52.4.1. GUC Variables

schedule.enabled (boolean)

Deprecated. Specifies whether pgpro_scheduler is enabled on your system.

Default: false.

For pgpro_scheduler 2.5 or higher, you can set the schedule.auto_enabled parameter to control whether pgpro_scheduler is enabled at the server start, or use schedule.enable()/schedule.disable() functions to enable/disable pgpro_scheduler on demand. To check if pgpro_scheduler is currently running, use the schedule.is_enabled() function.

schedule.auto_enabled (boolean)

Specifies whether to enable pgpro_scheduler at the server start.

Default: false.

schedule.database (text)

Specifies the databases for which pgpro_scheduler is enabled. Database names must be separated by commas.

Default: empty string.

schedule.database_to_connect (text)

The database to which pgpro_scheduler gets connected to receive Postgres Pro Enterprise cluster metadata. The specified database cannot be dropped while pgpro_scheduler is running. You can change this parameter only when restarting the server.

Default: postgres.

schedule.schema (text)

Deprecated. Specifies the name of a schema where the scheduler stores its tables and functions. If you need to change the default schema, use ALTER EXTENSION.

Default: schedule.

schedule.nodename (text)

Specifies the name of the cluster node on which pgpro_scheduler is running. Do not change or use this variable if you run a single-server cluster configuration.

On a cluster configured with multimaster, the node name is derived from the node ID provided by multimaster. For example, if the node ID is 3, the schedule.nodename variable is set to mtm-node-3.

However, if you explicitly set the `schedule.nodename` variable by editing the `postgresql.conf` file or running the `ALTER` command, `pgpro_scheduler` will ignore the node ID and use the provided value instead.

Default: `primary`.

`schedule.max_workers` (`integer`)

Specifies the maximum number of simultaneously running scheduled jobs in one database.

Default: `2`.

`schedule.max_parallel_workers` (`integer`)

Specifies the maximum number of parallel threads that can be used for executing one-time jobs.

Default: `2`.

`schedule.transaction_state` (`text`)

An internal variable containing the state of the executed job. `pgpro_scheduler` uses this variable when calculating the next job start time. Possible values are:

- `success` — transaction has finished successfully.
- `failure` — transaction has failed to finish.
- `running` — transaction is in progress.
- `undefined` — transaction has not started yet.

At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values. Other values may indicate an internal `pgpro_scheduler` error.

`schedule.enable_history` (`boolean`)

Log all schedule changes, including the name of the user who initiated the change and the time when this change occurred. If a new job is added, or the schedule of an existing job is modified, this information is stored in the `schedule.cron__history` table. If a job is deleted, this information is stored in the `schedule.cron__deleted` table. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

Default: `false`

F.52.4.2. SQL Schema

To store its internal tables and functions, `pgpro_scheduler` uses the `schedule` SQL schema. Direct access to tables is not recommended and should not be attempted. To manage job scheduling, use the functions defined by the `pgpro_scheduler` extension.

F.52.4.3. SQL Types

`pgpro_scheduler` defines the following types that are used by some of the `pgpro_scheduler` functions.

F.52.4.3.1. cron_rec

This type contains information about the scheduled job.

```
CREATE TYPE schedule.cron_rec AS(
    id integer,             -- job ID
    node text,              -- name of the node
                            -- on which to execute the job
    name text,              -- job name
    comments text,          -- comments about the job
```

```
    rule jsonb,             -- scheduling rules
    commands text[],        -- SQL commands to be executed
    run_as text,            -- username of the job executor
    owner text,             -- username of the job owner
    start_date timestamptz,   -- lower bound of the execution window;
                            -- NULL if unbound
    end_date timestamptz,     -- upper bound of the execution window;
                            -- NULL if unbound
    use_same_transaction boolean,   -- true if an array of SQL
                                    -- commands will be executed
                                    -- in a single transaction
    last_start_available interval,  -- maximum wait time for
                                    -- the scheduled job if all
                                    -- allowed workers are busy
    max_run_time interval,  -- maximum execution time
    onrollback text,        -- SQL statement to execute
                            -- if the main transaction fails
    max_instances int,      -- maximum number of simultaneously
                            -- running job instances
    next_time_statement text,   -- SQL statement to calculate
                                -- the next start time
    active boolean,         -- true if job is scheduled
                            -- successfully
    broken boolean          -- true if job has errors in
                            -- configuration that prevented
                            -- its further execution
);
```

F.52.4.3.2. cron_job

This type contains information about a particular job execution.

```
CREATE TYPE schedule.cron_job AS(
    cron integer,           -- job id
    node text,              -- name of the node
                            -- on which to execute the job
    scheduled_at timestamptz, -- scheduled execution time
    name text,              -- job name
    comments text,          -- comments about the job
    commands text[],        -- SQL statement to be executed
    run_as text,            -- username of the job executor
    owner text,             -- username of the job owner
    use_same_transaction boolean,   -- true if an array of SQL
                                    -- commands will be executed
                                    -- in a single transaction
    started timestamptz,      -- timestamp of the job execution start
    last_start_available timestamp, -- maximum wait time for
                                    -- the scheduled job if all
                                    -- allowed workers are busy
    finished timestamptz,     -- timestamp of the job
                            -- execution finish
    max_run_time interval,  -- maximum execution time
    onrollback text,        -- SQL statement to execute if the main
                            -- transaction fails
    next_time_statement text,   -- SQL statement to calculate
                                -- the next start time
    max_instances int,      -- the number of simultaneously
                            -- running job instances
    status job_status_t,    -- status of the task:
```

```
                                -- working, done, or error
    message text                -- error message
);
```

F.52.4.3.3. job_status_t

Enumerated type. Can take the following values:

- `working` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.

F.52.4.3.4. job_at_status_t

Enumerated type. Can take the following values:

- `submitted` — the job is submitted into the queue, but the execution has not started yet.
- `processing` — the job is being executed.
- `done` — job execution is complete.

F.52.4.3.5. timetable_job_type_t

Enumerated type. Can take the following values:

- `periodical` — a scheduled job.
- `onetime` — a one-time job.

F.52.4.3.6. timetable_job_status_t

Enumerated type. Can take the following values:

- `inprogress` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.
- `submitted` — the job is submitted into the queue, but the execution has not started yet.

F.52.4.4. Views

`pgpro_scheduler` provides several views for monitoring execution status of one-time jobs.

F.52.4.4.1. job_status View

Shows the status of one-time jobs belonging to the current user.

Table F.35. job_status View

Column Name	Column Type	Description
`id`	`bigint`	Job ID.
`node`	`text`	Name of the node on which the job is being executed.
`name`	`text`	Name of the job.
`comments`	`text`	Comments about the job.
`run_after`	`timestamp with time zone`	Timestamp after which the job execution must start.
`query`	`text`	SQL commands executed by the job.

Column Name	Column Type	Description
params	text[]	An array of parameters for the SQL query.
depends_on	bigint[]	An array of job IDs on which the job execution depends.
run_as	text	User or role whose rights are used to execute the job.
attempt	bigint	The number of execution attempts.
resubmit_limit	bigint	The maximum number of allowed job resubmissions.
max_wait_interval	interval	The maximum time interval to postpone the job execution if all background workers are busy at the scheduled moment.
max_duration	interval	Time interval during which the job can be executed.
submit_time	timestamp with time zone	Time when the job was submitted to the execution queue.
canceled	boolean	Specifies whether the job was canceled by user.
start_time	timestamp with time zone	Job execution start time.
is_success	boolean	• true — job execution completed successfully. • false — job execution completed with errors.
error	text	Error message.
done_time	timestamp with time zone	Time when the job execution completed.
status	job_at_status_t	Job status. See the Section F.52.4.3.4 for details.

F.52.4.4.2. all_job_status View

Shows the status of all one-time jobs. You must have superuser rights to access this view.

Table F.36. all_job_status View

Column Name	Column Type	Description
id	bigint	Job ID.
node	text	Name of the node on which the job is being executed.
name	text	Name of the job.
comments	text	Comments about the job.
run_after	timestamp with time zone	Timestamp after which the job execution must start.
query	text	SQL commands executed by the job.
params	text[]	An array of parameters for the SQL query.

Column Name	Column Type	Description
depends_on	bigint[]	An array of job IDs on which the job execution depends.
run_as	text	User or role whose rights are used to execute the job.
owner	text	The user who created the job.
attempt	bigint	The number of execution attempts.
resubmit_limit	bigint	The maximum number of allowed job resubmissions.
max_wait_interval	interval	The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment.
max_duration	interval	Time interval during which the job can be executed.
submit_time	timestamp with time zone	Time when the job was submitted to the execution queue.
canceled	boolean	Specifies whether the job was canceled by user.
start_time	timestamp with time zone	Job execution start time.
is_success	boolean	• true — job execution completed successfully. • false — job execution completed with errors.
error	text	Error message.
done_time	timestamp with time zone	Time when the job execution completed.
status	job_at_status_t	Job status. See the Section F.52.4.3.4 for details.

F.52.4.5. Audit Tables

The following tables store all schedule changes if the schedule.enable_history parameter is set to true. If you later disable the schedule.enable_history parameter, the history of the already recorded changes is preserved.

F.52.4.5.1. schedule.cron_history Table

Registers job scheduling changes. Whenever a new job is scheduled, or the schedule for an existing job is changed, a new row is inserted into this table to record the following information:

- All details about the scheduled job, as defined by the cron_rec data type. For details on the cron_rec type, see Section F.52.4.3.
- submitter — name of the user who updated the schedule.
- version_id — a unique ID for each registered change in the schedule.
- submit_time — time when the schedule was updated.

F.52.4.5.2. schedule.cron_deleted Table

Registers all jobs that were removed from the schedule:

- cron — ID of the deleted job.

- `submitter` — name of the user who deleted the job.
- `submit_time` — time when the job was deleted.

F.52.4.6. Functions

`pgpro_scheduler` provides two separate sets of functions for managing scheduled and one-time jobs, as well as several common functions that can toggle `pgpro_scheduler` on and off for your database and show the current status of the extension:

- Section F.52.4.6.1
- Section F.52.4.6.2
- Section F.52.4.6.3
- Section F.52.4.6.4

> **Important**
>
> With each job, you can only use the function specifically tailored for this job type.

F.52.4.6.1. Common Functions

These functions facilitate `pgpro_scheduler` management.

`schedule.enable()`

Enables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if the command has failed.

`schedule.is_enabled()`

Checks whether `pgpro_scheduler` is enabled.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if `pgpro_scheduler` is not currently running.

`schedule.disable()`

Disables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is disabled.
- `false` if the command has failed.

`schedule.start()`

Launches `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` started successfully.
- `false` — if the command has failed, or `pgpro_scheduler` is already started.

`schedule.stop()`

Stops `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` is stopped.
- `false` — if the command has failed, or `pgpro_scheduler` is not running.

`schedule.status()`

Returns the status of `pgpro_scheduler` background workers:

- `pid` — process ID of the background worker. If the process ID is `NULL`, the background worker is not running.
- `database` — name of the database to which the background worker is connected.
- `type` — type of the background worker:
  - `supervisor` — distributes the scheduled jobs between the databases.
  - `database manager` distributes the scheduled jobs within the database.
  - `cron job executor` executes a scheduled job.
  - `at job executor` executes a one-time job.

`schedule.version()`

Returns `pgpro_scheduler` version.

F.52.4.6.2. Functions for Managing Scheduled Jobs

`schedule.create_job(`*`options`* `jsonb)`

Creates an active job and returns the job ID.

Alternative Syntax:

```
schedule.create_job(cron text, commands text [, node text])
schedule.create_job(cron text, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone, commands text [, node text])
schedule.create_job(dates timestamp with time zone, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone[], commands text [, node text])
schedule.create_job(dates timestamp with time zone[], commands text[] [, node text])
```

Arguments:

- *`options`* — a `jsonb` object defining all the job properties. You do not need to define other parameters if the *`data`* is set. All the available `jsonb` keys are listed in Table F.37.

  Type: `jsonb`

- *`cron`* — a crontab-like string defining the job schedule.

  Type: `text`

- *`dates`* — the exact date or an array of dates for job execution.

  Type: `timestamp with time zone`, `timestamp with time zone[]`

- *`commands`* — SQL statement to execute. You can pass one or more SQL commands separated by semicolons, or an array of SQL commands. When passed as an array, SQL commands are executed in separate transactions.

  Type: `text`, `text[]`

- *`node`* — the name of the node on which the scheduled jobs run. Optional. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.

  Type: `text`

Return values:

- ID of the created job.

Table F.37. `jsonb` Keys for Job Scheduling

Key	Type	Description
`cron`	`text`	A crontab-like string defining the job schedule. A traditional five-field or nonstandard six-field (seconds in the first field) `crontab` format may be used. You can combine `cron` with `rule` and `dates` keys, but at least one of them is mandatory. Alternatively, the following keywords can be used instead of a `crontab` string to specify when the job will be started: • `@every_second` — each second • `@hourly` — at the beginning of each hour • `@daily` — at the beginning of each day • `@midnight` — at the beginning of each day • `@weekly` — at the beginning of each week • `@monthly` — at the beginning of each month • `@yearly` — at the beginning of each year • `@annually` — at the beginning of each year
`dates`	`timestamp with time zone`, `timestamp with time zone[]`	The exact date or an array of dates when the scheduled job will be executed. You can combine `dates` with `rule` and `cron` keys, but at least one of them is mandatory.
`rule`	`jsonb`	A `jsonb` object defining the job schedule. Mandatory, if both `cron` and `dates` keys are undefined. The `rule` object includes one or more of the following keys: • `seconds` — seconds; an array of integers in range [0, 59] • `minutes` — minutes; an array of integers in range [0, 59] • `hours` — hours; an array of integers in range [0, 23]

Key	Type	Description
		• days — days of the month; an array of integers in range [1, 31] • months — months; an array of integers in range [1, 12] • wdays — days of the week; an array of integers in range [0, 6], where 0 is Sunday. • onstart — integer value 0 or 1. If onstart is set to 1, the job is executed only once when pgpro_scheduler is started.
commands	text, text[]	SQL statements to execute. You can pass one or more SQL statements separated by semicolons, or an array of SQL statements. When passed as an array, SQL statements are executed in separate transactions by default. You can change this behavior by setting the use_same_transaction key.
name	text	Optional. Job name.
node	text	Optional. The name of the node on which the scheduled jobs run. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.
comments	text	Optional. Comments about the scheduled job.
run_as	text	Optional. The user whose rights are used to execute the job.
start_date	timestamp with time zone	Optional. The start of the timeframe when the scheduled job can be executed. This key can be NULL.
end_date	timestamp with time zone	Optional. The end of the timeframe when the scheduled job can be executed. This key can be NULL.
use_same_transaction	boolean	Optional. If set to true, forces an array of SQL statements to be executed in a single transaction. Default: false
last_start_available	interval	Optional. The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if

Key	Type	Description
		this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is NULL or not set, the job can wait forever. Default: NULL.
max_instances	integer	Optional. The maximum number of job instances that can be executed simultaneously. Default: 1.
max_run_time	interval	Optional. The maximum time interval during which the scheduled job can be executed. If this key is NULL or not set, there are no time limits. Default: NULL.
onrollback	text	Optional. SQL statement to be executed if the main transaction fails.
next_time_statement	text	Optional. SQL statement to calculate the start time for the next job execution. For details, see Section F.52.3.1.3.

`schedule.set_job_attributes(`*`job_id`* `integer, `*`data`* `jsonb)`

Updates properties of the existing job.

Arguments:

- *`job_id`* — identifier of the existing job.
- *`data`* — a `jsonb` object with properties to be edited. For the list of keys and their structure, see Table F.37.

Return values:

- *`true`* — job properties were updated successfully.
- *`false`* — job properties were not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

`schedule.set_job_attribute(`*`job_id`* `integer, `*`name`* `text, `*`value`* `text || anyarray)`

Updates a property of the existing job.

Arguments:

- *`job_id`* — identifier of the existing job.
- *`name`* — property name.
- *`value`* — property value.

See Table F.37 for the list of job properties you can update. Some values are of array types. They should be passed as an array. If a value of a wrong type is passed, an exception is raised.

Return values:

- *`true`* — job property was updated successfully.
- *`false`* — job property was not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

`schedule.deactivate_job(`*`job_id`* `integer)`

Deactivates the job and suspends its further scheduling and execution.

Arguments:

- *`job_id`* — identifier of the existing job.

Return values:

- `true` — the job is deactivated successfully.
- `false` — job deactivation failed.

`schedule.activate_job(`*`job_id`* `integer)`

Activates a job and starts its scheduling and execution.

Arguments:

- *`job_id`* — identifier of the existing job.

Return values:

- `true` — the job was activated successfully.
- `false` — job activation failed.

`schedule.drop_job(`*`job_id`* `integer)`

Deletes a job.

Arguments:

- *`job_id`* — identifier of the existing job.

Return values:

- `true` — the job was deleted successfully.
- `false` — job was not deleted.

`schedule.get_job(`*`job_id`* `integer)`

Returns information about the specified job.

Arguments:

- *`job_id`* — identifier of the existing job.

Return values:

- An object of type `cron_rec`.

For details on the `cron_rec` type, see Section F.52.4.3.

`schedule.get_owned_cron(`*`username`* `text)`

Retrieves the list of jobs owned by the specified user.

Arguments:

- *`username`* — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs owned by the specified user. If the *`username`* is omitted, the session username is used. You must have superuser rights to retrieve jobs owned by another user.

For details on the `cron_rec` type, see Section F.52.4.3.

`schedule.get_cron()`

Retrieves the list of jobs executed by the session user.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs executed by the session user. You must have superuser rights to retrieve the jobs.

For details on the `cron_rec` type, see Section F.52.4.3.

`schedule.get_active_jobs(`*`username`* `text)`

Returns the list of jobs currently being executed by the specified user.

Arguments:

- *`username`* — username, optional.

If *`username`* is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see Section F.52.4.3.

`schedule.get_active_jobs()`

Returns the list of jobs being currently executed. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see Section F.52.4.3.

`schedule.get_log()`

Returns the list of all completed jobs. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see Section F.52.4.3.

`schedule.get_user_log(`*`username`* `text)`

Returns the list of completed jobs executed by the specified user.

Arguments:

- *`username`* — username, optional.

If *`username`* is omitted, the session username is used. You must have superuser rights to retrieve the list of jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see Section F.52.4.3.

`schedule.clean_log()`

Deletes all records with information about the completed jobs. You must have superuser rights to call this function.

Return values:

- The number of records deleted.

`schedule.nodename()`

Returns the current node name.

F.52.4.6.3. Functions for Managing One-Time Jobs

`schedule.submit_job(`*`query`* `text [`*`options...`*`])`

Submits a job for immediate or delayed one-time execution. By default, the job is scheduled for immediate execution and can run in parallel with other scheduled jobs. To submit a job with a delayed start, you can set the execution start time using the *`run_after`* argument, or pass an array of job IDs in the *`depends_on`* argument to schedule job execution right after these jobs are complete.

Arguments:

- *`query`* — SQL commands to execute.

  Type: `text`

- *`params`* — an array of parameters for the SQL query that can substitute numbered placeholders in the *`query`* argument, such as $1, $2, etc. Default: `NULL`

  Type: `text[]`

- *`run_after`* — a timestamp after which the job execution starts. If this argument is set to `NULL`, the job is scheduled for immediate execution. You can also use the *`depends_on`* argument to delay the job start. Default: `NULL`

  Type: `timestamp with time zone`

- *`node`* — the name of the node on which to execute the job. Default: `NULL`

  Type: `text`

- *`max_duration`* — the maximum time interval during which the job can be executed. If this time is exceeded, the job is forced to stop. If this argument is `NULL` or not set, there are no time limits. Default: `NULL`

  Type: `interval`

- *`max_wait_interval`* — the maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is `NULL` or not set, the job can wait forever. Default: `NULL`

  Type: `interval`

- *`run_as`* — user or role whose rights are used to execute the job. If *`run_as`* is set to `NULL`, the job is executed with the rights of the current user. You must have superuser rights to set this argument. Default: `NULL`

  Type: `text`

- *depends_on* — an array of job IDs. The created job starts immediately after the specified jobs complete the execution. This argument is an alternative to *run_after*. Default: NULL

  Type: bigint[]

- *name* — name of the job. Default: NULL

  Type: text

- *comments* — comments about the job.

  Type: text

- *resubmit_limit* — maximum number of times the job can be resubmitted for execution. See the schedule.resubmit() function for details. Default: 100

  Type: bigint

Return values:

- ID of the created job.

  Type: bigint

schedule.get_self_id()

Returns the ID of the job, in the context of which it was called. The returned ID is of the bigint type. This function must be called inside the *query* of the schedule.submit_job() function. Otherwise, an exception is raised.

Return values:

- Job ID.

schedule.cancel_job(*job_id* bigint)

Cancels all subsequent runs of the specified job. If the job is currently being executed, it will not be interrupted, but cannot be resubmitted. You must have superuser rights or be the owner of the job to call this function.

Arguments:

- *job_id* — identifier of the job to cancel.

Return values:

- true if the operation completed successfully.
- false if the operation failed.

schedule.resubmit(*run_after* interval default NULL)

Sets the start time for the next execution of the job, without interrupting the current job run. This function must be called inside the *query* argument of the schedule.submit_job() function. Otherwise, an exception is raised. If this function is called several times within a single job execution, only the last function call is taken into account.

Arguments:

- *run_after* — time interval after which the job will be resubmitted for execution. If the time interval is less than a second but greater than zero, it is rounded to 1 second. Intervals longer than 1 second are rounded to integral values. If 0 is passed, the job is resubmitted immediately after execution. Default: 1 second

  Type: interval

Return values:

- The number of seconds after which the job will be resubmitted for execution.

F.52.4.6.4. Functions for Managing Scheduled and One-Time Jobs

`schedule.timetable(`*`start_time`* `timestamp with time zone, `*`end_time`*`timestamp with time zone)`

Returns a table, which describes all the jobs, both repeated and one-time, that are scheduled to execute within the specified time interval.

Table F.38. schedule.timetable Columns

Column Name	Column Type	Description
`id`	`bigint`	Job ID, which is unique for the jobs of this type.
`type`	`timetable_job_type_t`	Job type. See Section F.52.4.3.5 for details.
`node`	`text`	Name of the node on which the job is being executed.
`name`	`text`	Name of the job.
`comments`	`text`	Comments about the job.
`commands`	`text[]`	An array of SQL commands executed by the job.
`scheduled_at`	`timestamp with time zone`	Scheduled job execution time.
`start_time`	`timestamp with time zone`	Job execution start time.
`done_time`	`timestamp with time zone`	Time when the job execution completed.
`status`	`timetable_job_status_t`	Job status. See Section F.52.4.3.6 for details.
`error`	`text`	Error message.

F.52.5. Authors

Postgres Professional, Moscow, Russia

F.53. pgpro_sfile — storage for large objects

The pgpro_sfile module allows storing multiple large objects. It is similar to Oracle LOBs. pgpro_sfile provides an engine for storing large objects in a set of tables controlled by the extension. Each object consists of chunks, or blocks. Blocks are split into pages of ~8kB size. The maximum number of objects, number of blocks and object size in bytes are limited by the size of the bigint type (2^63 - 1). A pgpro_sfile large object is called *sfile object*.

F.53.1. Storage Engine

sfile objects are stored in tables created and controlled by pgpro_sfile. Regular tables only store the identifier of each sfile object as a reference to tables created by pgpro_sfile. Once an sfile object is created, it can be loaded, read, truncated and deleted, and these operations do not affect regular tables where it is used.

The storage engine is a set of the following storage tables:

- SF_DESCRIPTOR — a registry where descriptors of all sfile objects are stored.
- SF_PARTITION — a registry of storage tables (partitions). Stores information about SF_PAGE_XX tables.
- SF_BLOCK — a registry of sfile object blocks. Each block can include several pages of sfile objects.
- SF_PAGE_XX — tables with sfile object data pages.
- SF_OPTION — a table with sfile object options. Currently there is one option TABLESPACE, which allows setting the tablespace where sfile objects are stored.

All the tables, except SF_OPTION, are created in a special pgpro_sfile_data schema. The SF_OPTION table is created during the pgpro_sfile installation. SF_DESCRIPTOR, SF_PARTITION, and SF_BLOCK tables are created during the pgpro_sfile initialization, and SF_PAGE_XX tables are created when an sfile object is written to the database and are tracked in the SF_PARTITION registry.

Next sections describe the structure of the storage tables.

F.53.1.1. SF_OPTION

The SF_OPTION table has the following fields:

opt_type	smallint	Option type: GLOBAL = 0, TABLE = 1, or OBJECT = 2. Currently GLOBAL is only supported.
opt_name	name	Unique option name.
opt_value	name	Option value.

F.53.1.2. SF_DESCRIPTOR

The SF_DESCRIPTOR table has the following fields:

sf_id	bigint	Unique sfile object identifier.
sf_name	name	sfile object name.
sf_persistence	smallint	Storage type of the sfile object: RELPERSISTENCE_PERMANENT="p" or RELPERSISTENCE_UNLOGGED="u".
sf_state	smallint	Set of bits that describe the sfile object state. For example: SF_STATE_DELETED =1.

sys_creation_date	timestamp	Date and time of the sfile object creation.
sys_update_date	timestamp	Date and time of the last update of the sfile object.
sf_json_opts	text	Options of the sfile object in the text or JSON format.
sf_type	text	Manually set sfile object type.
tbs_identity	text	Name of the tablespace where the sfile object will be stored.

F.53.1.3. SF_PARTITION

The SF_PARTITION table has the following fields:

part_id	int	Unique partition identifier.
part_data_size	bigint	Number of blocks that are currently stored in the partition.
part_persistence	smallint	Data storage type in the partition: RELPERSISTENCE_PERMANENT="p" or RELPERSISTENCE_UNLOGGED="u".
rel_identity	text	Name of the table that stores the partition data.
tbs_identity	text	Name of the tablespace that stores the partition data.

F.53.1.4. SF_BLOCK

The SF_BLOCK table has the following fields:

sf_id	bigint	Unique sfile object identifier.
block_id	bigint	Unique identifier of the block in the sfile object. The value of the *a_sf_index* argument of sf_write is written here.
part_id	int	Identifier of the partition where the block data is stored.
block_size	int	Block size, in bytes.
block_start_page	int	Sequential number of the block first page, the block numbering starts at 1.
block_end_page	int	Sequential number of the block last page, the block numbering starts at 1.
sys_creation_date	timestamp	Date and time of the block creation .
sys_update_date	timestamp	Date and time of the block last update.

F.53.1.5. SF_PAGE_XX

Each SF_PAGE_XX table has the following fields:

sf_id	bigint	Unique sfile object identifier.
block_id	bigint	Unique identifier of the block that includes the page.
page_no	int	Sequential number of the page in the block.
data	bytea	The buffer to store the sfile object data. The maximum data size to store in the data buffer is 8096 bytes.

F.53.2. Installation

The pgpro_sfile extension is included in Postgres Pro Enterprise. To enable pgpro_sfile, create the extension using the following query:

```
CREATE EXTENSION pgpro_sfile;
```

F.53.3. Functions

The pgpro_sfile functions allow performing various operations with sfile objects, such as creating, writing, reading, deleting and more. To access IDs of sfile objects, these functions use the sfile data type. To store object IDs, a new column of the sfile data type must be added to the table.

`sf_initialize()` returns `void`

Initializes the storage of sfile objects. The function creates the pgpro_sfile_data schema and then creates the needed tables and sequences in this schema. Call this function right after installation of the extension.

`sf_deinitialize()` returns `void`

Performs cascading delete of the pgpro_sfile_data schema. Call this function before deleting the extension to delete all the sfile object data. Superuser privileges are required to call this function.

`sf_create(`*a_sf_name* `text, `*a_sf_persistence* `text, `*a_sf_json_options* `text[, `*a_sf_tablespace* `text])` returns `sfile`

Creates a new sfile object with the name *a_sf_name* and returns the ID of the object. The object will be logged or unlogged depending on the value of *a_sf_persistence*, which must be LOGGED or UNLOGGED, and the *a_sf_json_options* argument must contain JSON with options. The *a_sf_tablespace* argument allows you to specify the tablespace where the sfile object will be stored, otherwise, the default tablespace is used.

This function adds a descriptor of the sfile object with the zero size to the SF_DESCRIPTOR relation. So a call to sf_is_empty on a newly created object returns TRUE, as well as sf_is_valid. No blocks or partitions are created by sf_create.

`sf_create_empty([`*a_sf_tablespace* `text]) returns sfile`

Creates a new empty sfile object with an autogenerated name (sf_gen_XX) and empty options and returns the ID of the object. The *a_sf_tablespace* argument allows you to specify the tablespace where the sfile object will be stored, otherwise, the default tablespace is used.

`sf_write(`*a_sf* `sfile, `*a_sf_data* `bytea[, `*a_sf_index* `bigint])` returns `integer`

Inserts the new data block *a_sf_data* with the index specified by the *a_sf_index* argument into the sfile object specified by its ID *a_sf* and returns the number of bytes added. The current timestamp is used as the default index. Passing *a_sf_index* <= 0 results in an error.

This function first checks whether the sfile object was already written in order to figure out whether the partition table SF_PAGE_XX is available and has enough free space to write the block. If the

partition is not available or it is the first write, all other partitions are checked and the first available is locked for writing. If no partition is available, a new one is created and added to the SF_PARTITION registry. Then a new block entry is initialized in SF_BLOCK, the block is divided into pages of ~8kB size, and these pages are written to the previously locked SF_PAGE_XX partition. When the block is written, the size of the data is adjusted in the part_data_size field of the SF_PARTITION table.

`sf_read(a_sf sfile[, a_offset bigint, a_length integer])` returns `bytea`

Reads the number of bytes specified by the *a_length* from the `sfile` object specified by its ID *a_sf* at the offset specified by the *a_offset* argument. Up to ~1 GB can be read due to the `varlena` limitation. The default is ~1 GB. The default offset is 0. Returns the buffer with the data read.

`sf_size(a_sf sfile)` returns `bigint`

Retrieves the `sfile` object size.

`sf_truncate(a_sf sfile)` returns `bigint`

Truncates the `sfile` object, that is, deletes all data (blocks) but leaves the object intact, and returns the new `sfile` object size, that is, 0. So a subsequent call to sf_is_valid for this object continues to return `TRUE`, and a call to sf_is_empty also returns `TRUE`.

`sf_delete(a_sf sfile)` returns `bigint`

Deletes the `sfile` object and returns the amount of data deleted. The function deletes all the blocks of data and then removes the object descriptor from SF_DESCRIPTOR. Since then, the object is not available, so a call to sf_is_valid for this object returns `FALSE`.

`sf_describe(a_sf sfile)` returns `cstring`

Retrieves the `sfile` object descriptor data and returns it as text.

`sf_get_json_options(a_sf sfile)` returns `cstring`

Retrieves JSON with options provided when the `sfile` object was created (see sf_create).

`sf_find(a_sf_name text)` returns `sfile`
`sf_find(a_sf_id bigint)` returns `sfile`

Searches the `sfile` object by the specified name or by the specified unique ID of the `bigint` type and returns the `sfile` object ID. See also Example F.7 for more information.

`sf_set_option(a_opt_name text, [a_opt_value text, a_opt_type text])` returns `void`

Sets the option (pgpro_sfile setting) specified by the *a_opt_name* argument in SF_OPTION. The only argument values that are currently supported are `TABLESPACE` for *a_opt_name* and `GLOBAL` for *a_opt_type*. The default for *a_opt_value* is NULL, and the default for *a_opt_type* is `GLOBAL`. The pgpro_sfile behavior with the `TABLESPACE` option, is to check whether the specified tablespace exists and if it does not, raise an error.

`sf_get_option(a_opt_name text)` returns `cstring`

Retrieves the option (pgpro_sfile setting) with the specified name from SF_OPTION.

`sf_delete_option(a_opt_name text)` returns `void`

Deletes the option (pgpro_sfile setting) with the specified name from SF_OPTION.

`sf_is_valid(a_sf sfile)` returns `bool`

Returns `TRUE` if the argument specifies a valid `sfile` object and `FALSE` otherwise.

`sf_is_empty(a_sf sfile)` returns `bool`

Returns `TRUE` if the argument specifies a valid and empty `sfile` object and `FALSE` otherwise.

`sf_is_logged(a_sf sfile)` returns `bool`

Returns `TRUE` if the argument specifies a logged (permanent) `sfile` object and `FALSE` otherwise.

`sf_trim(a_sf sfile, a_length bigint)` returns `bigint`

Trims the `sfile` object specified by the `a_sf` argument to the size specified by the `a_length` argument. The trimmed data is deleted. Returns the new object size. If the `sfile` object size is less than `a_length`, returns the actual object size.

`sf_set_type(a_sf sfile, a_type text)` returns `void`

Sets the custom type specified in the `a_type` argument to the `sfile` object specified by `a_sf`.

`sf_get_type(a_sf sfile)` returns `cstring`

Retrieves the custom object type of the specified `sfile` object as text.

`sf_md5(a_sf sfile)` returns `text`

Calculates MD5 hash for the specified `sfile` object.

F.53.4. Parallel Processing

To speed up interactions with large objects, read functions sf_read/sf_size and write function the sf_write can be performed in parallel. These functions take an `AccessShareLock` lock for the `sfile` object, which does not forbid reading the object. Each of `sf_read`/`sf_size` functions releases this lock right after execution of the operation, while `sf_write` holds the lock up to the end of the transaction to prevent deletion/trunction/trimming of the `sfile` object before the end of the transaction. In more detail, the changes made by `sf_write` to the SF_BLOCK and SF_PAGE_XX tables are not visible to a parallel session, and if the `AccessShareLock` lock is removed before the end of the transaction, the `sfile` object can be deleted by another session, which is unaware of the rows added to `SF_BLOCK` and `SF_PAGE_XX`. As a result, the `sfile` object will be deleted while these rows will remain intact.

While writing, blocks of one object can be written from several sessions, and the block write sequence depends on the time of the `sf_write` call. To control the block write sequence, pass the `a_sf_index` argument. If it is not passed, the call timestamp is used instead, which is the default. Each call to `sf_write` takes an `AccessExclusiveLock` for partitions where blocks are written, which means that it is not permitted to write blocks in the same partition from different sessions as it is not possible to simultaneously modify the `part_data_size` field of the SF_PARTITION table. However, writing `sfile` object blocks from several sessions into different partitions is permitted.

sf_trim, sf_truncate and sf_delete functions cannot be performed in parallel as they take an `AccessExclusiveLock` for the `sfile` object.

F.53.5. Examples

Example F.6. Basic Usage of pgpro_sfile

```
-- Create pgpro_sfile extension
CREATE EXTENSION pgpro_sfile;

-- Initialize sfile object storage
SELECT sf_initialize();

-- Create test table
CREATE TABLE test_sfile (id int, l sfile);

-- Create and store sfile object
INSERT INTO test_sfile VALUES (1, sf_create('sf', 'LOGGED', NULL));

-- Write data to sfile object and check data written
```

```
SELECT sf_write(t.l, '1234567890'::bytea) FROM test_sfile t WHERE id = 1;
SELECT encode(b, 'escape'), length(b) FROM (SELECT sf_read(t.l, 0, NULL) b FROM
 test_sfile t WHERE id = 1) x;

-- Trim sfile object and check data
SELECT sf_trim(t.l, 5) FROM test_sfile t WHERE id = 1;
SELECT encode(b, 'escape'), length(b) FROM (SELECT sf_read(t.l, 0, NULL) b FROM
 test_sfile t WHERE id = 1) x;

-- Remove table
DROP TABLE test_sfile;

-- Delete data of all sfile objects
SET client_min_messages = WARNING;
SELECT sf_deinitialize();
RESET client_min_messages;

-- Delete pgpro_sfile extension
DROP EXTENSION pgpro_sfile;
```

This example produces the following output:

```
CREATE EXTENSION
 sf_initialize
---------------

(1 row)

CREATE TABLE
INSERT 0 1
 sf_write
----------
       10
(1 row)

   encode   | length
------------+--------
 1234567890 |     10
(1 row)

 sf_trim
---------
       5
(1 row)

 encode | length
--------+--------
 12345  |      5
(1 row)

DROP TABLE
SET
 sf_deinitialize
-----------------
```

```
(1 row)
```

Example F.7. Usage of Type Cast Instead of `sf_find`

```
-- Create pgpro_sfile extension
CREATE EXTENSION pgpro_sfile;

-- Initialize sfile object storage
SELECT sf_initialize();

-- Create sfile object
SELECT sf_create('test', 'LOGGED', NULL);

-- Write to sfile using sfile name
SELECT sf_write(sf_find('test'), '1234567890'::bytea);

-- Write to sfile using sfile identifier
SELECT sf_write(1::bigint::sfile, '1234567890'::bytea);
```

This example produces the following output:

```
CREATE EXTENSION
 sf_initialize
---------------
(1 row)
 sf_create
-----------
 1
(1 row)
 sf_write
----------
       10
(1 row)
 sf_write
----------
       10
(1 row)
```

F.53.6. Authors

Postgres Professional, Moscow, Russia

F.54. pg_query_state — a facility to know the current state of query execution on working backend

The pg_query_state module provides facility to know the current state of query execution on working backend.

F.54.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

F.54.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

F.54.3. Installation

To install pg_query_state run in psql:

```
CREATE EXTENSION pg_query_state;
```

Then modify shared_preload_libraries parameter in postgres.conf as following:

```
shared_preload_libraries = 'pg_query_state'
```

It will require to restart the Postgres Pro instance.

F.54.4. Function pg_query_state

```
pg_query_state(integer  pid,
               verbose  boolean DEFAULT FALSE,
               costs    boolean DEFAULT FALSE,
               timing   boolean DEFAULT FALSE,
               buffers  boolean DEFAULT FALSE,
               triggers boolean DEFAULT FALSE,
               format   text    DEFAULT 'text')
  returns TABLE (pid integer,
                 frame_number integer,
                 query_text text,
                 plan text,
                 leader_pid integer)
```

Extract current query state from backend with specified pid. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of pg_query_state has type TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer). It represents tree structure consisting of leader

process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in EXPLAIN ANALYZE output and statistics for current loop if node have not finished.

Optional arguments:

- verbose - use EXPLAIN VERBOSE for plan printing;
- costs - costs for each node;
- timing - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain WARNING message `timing statistics disabled`;
- buffers - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain WARNING message `buffers statistics disabled`;
- triggers - include triggers statistics in result plan trees;
- format - EXPLAIN format to be used for plans printing, possible values: text, xml, json, yaml.

If callable backend is not executing any query the function prints INFO message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints ERROR message `permission denied`.

F.54.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- pg_query_state.enable - disable (or enable) pg_query_state completely, default value is `true`
- pg_query_state.enable_timing - collect timing data for each node, default value is `false`
- pg_query_state.enable_buffers - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. `WARNING`: if pg_query_state.enable_timing is turned off the calling side cannot get time statistics, similarly for pg_query_state.enable_buffers parameter.

F.54.6. Examples

Set maximum number of parallel workers on `gather`

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
 1 ]+-----------------------------------------------------------------------------------------
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
                                                +
             |   ->  Gather (Current loop: actual rows=0, loop number=1)
                                                +
             |         Workers Planned: 2
                                                +
             |         Workers Launched: 2
                                                +
             |         ->  Partial Aggregate (Current loop: actual rows=0, loop
 number=1)                                        +
             |               ->  Nested Loop (Current loop: actual rows=12, loop
 number=1)                                       +
             |                     Join Filter: (foo.c1 = bar.c1)
                                                +
             |                     Rows Removed by Join Filter: 5673232
                                                +
             |                     ->  Parallel Seq Scan on foo (Current loop: actual
 rows=12, loop number=1)                          +
             |                     ->  Seq Scan on bar (actual rows=500000 loops=11)
 (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
 2 ]+-----------------------------------------------------------------------------------------
pid          | 49324
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
                                                +
             |   ->  Nested Loop (Current loop: actual rows=10, loop number=1)
                                                +
             |         Join Filter: (foo.c1 = bar.c1)
                                                +
             |         Rows Removed by Join Filter: 4896779
                                                +
             |         ->  Parallel Seq Scan on foo (Current loop: actual rows=10, loop
 number=1)                                      +
             |         ->  Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
 actual rows=396789, loop number=10)
leader_pid   | 49265
-[ RECORD
 3 ]+-----------------------------------------------------------------------------------------
pid          | 49323
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
                                                +
             |   ->  Nested Loop (Current loop: actual rows=11, loop number=1)
                                                +
```

```
             |         Join Filter: (foo.c1 = bar.c1)
                                                  +
             |         Rows Removed by Join Filter: 5268783
                                                  +
             |         ->  Parallel Seq Scan on foo (Current loop: actual rows=11, loop
 number=1)                                        +
             |         ->  Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
 actual rows=268794, loop number=11)
leader_pid   | 49265
```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their `leader_pid` column's values clarify that these workers belong to the main backend. `Seq Scan` node has statistics on passed loops (average number of rows delivered to `Nested Loop` and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```
postgres=# select * from pg_query_state(49265);
-[ RECORD
 1 ]+-----------------------------------------------------------------------------------------
pid          | 49265
frame_number | 0
query_text   | select n_join_foo_bar();
plan         | Result (Current loop: actual rows=0, loop number=1)
leader_pid   | (null)
-[ RECORD
 2 ]+-----------------------------------------------------------------------------------------
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | Result (Current loop: actual rows=0, loop number=1)
                                       +
             |   InitPlan 1 (returns $0)
                                       +
             |     ->  Aggregate (Current loop: actual rows=0, loop number=1)
                                       +
             |           ->  Nested Loop (Current loop: actual rows=51, loop number=1)
                                       +
             |                 Join Filter: (foo.c1 = bar.c1)
                                       +
             |                 Rows Removed by Join Filter: 51636304
                                       +
             |                 ->  Seq Scan on bar (Current loop: actual rows=52, loop
 number=1)                                  +
             |                 ->  Materialize (actual rows=1000000 loops=51) (Current
 loop: actual rows=636355, loop number=52)+
             |                       ->  Seq Scan on foo (Current loop: actual
 rows=1000000, loop number=1)
leader_pid   | (null)
```

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+------------------------------------------------------------
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {                                                          +
             |   "Plan": {                                                +
             |     "Node Type": "Function Scan",                          +
             |     "Parallel Aware": false,                               +
             |     "Function Name": "n_join_foo_bar",                     +
             |     "Alias": "n_join_foo_bar",                             +

F.55. pgrowlocks — show a table's row locking information

The pgrowlocks module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, roles with privileges of the pg_stat_scan_tables role, and users with SELECT permissions on the table.

F.55.1. Overview

```
pgrowlocks(text) returns setof record
```

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F.39.

Table F.39. pgrowlocks Output Columns

Name	Type	Description
locked_row	tid	Tuple ID (TID) of locked row
locker	xid	Transaction ID of locker, or multixact ID if multitransaction; see Section 75.1
multi	boolean	True if locker is a multitransaction
xids	xid[]	Transaction IDs of lockers (more than one if multitransaction)
modes	text[]	Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.
pids	integer[]	Process IDs of locking backends (more than one if multitransaction)

pgrowlocks takes AccessShareLock for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an ACCESS EXCLUSIVE lock is taken on the table, pgrowlocks will be blocked.
2. pgrowlocks is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

pgrowlocks does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
  WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

F.55.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
 locked_row | locker | multi | xids  |     modes      |  pids
------------+--------+-------+-------+----------------+--------
 (0,1)      |    609 | f     | {609} | {"For Share"}  | {3161}
 (0,2)      |    609 | f     | {609} | {"For Share"}  | {3161}
 (0,3)      |    607 | f     | {607} | {"For Update"} | {3107}
```

```
 (0,4)      |     607 | f      | {607} | {"For Update"} | {3107}
(4 rows)
```

Tatsuo Ishii

F.56. pg_stat_statements — track statistics of SQL planning and execution

The pg_stat_statements module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding pg_stat_statements to shared_preload_libraries in postgresql.conf, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if compute_query_id is set to auto or on, or any third-party module that calculates query identifiers is loaded.

When pg_stat_statements is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views pg_stat_statements and pg_stat_statements_info, and the utility functions pg_stat_statements_reset and pg_stat_statements. These are not available globally but can be enabled for a specific database with CREATE EXTENSION pg_stat_statements.

F.56.1. The pg_stat_statements View

The statistics gathered by the module are made available via a view named pg_stat_statements. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F.40.

Table F.40. pg_stat_statements Columns

Column Type Description
userid oid (references pg_authid .oid) OID of user who executed the statement
dbid oid (references pg_database .oid) OID of database in which the statement was executed
toplevel bool True if the query was executed as a top-level statement (always true if pg_stat_statements.track is set to top)
queryid bigint Hash code to identify identical normalized queries.
query text Text of a representative statement
plans bigint Number of times the statement was planned (if pg_stat_statements.track_planning is enabled, otherwise zero)
total_plan_time double precision Total time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
min_plan_time double precision Minimum time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
max_plan_time double precision Maximum time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
mean_plan_time double precision

Column Type Description
Mean time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
stddev_plan_time double precision Population standard deviation of time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
calls bigint Number of times the statement was executed
total_exec_time double precision Total time spent executing the statement, in milliseconds
min_exec_time double precision Minimum time spent executing the statement, in milliseconds
max_exec_time double precision Maximum time spent executing the statement, in milliseconds
mean_exec_time double precision Mean time spent executing the statement, in milliseconds
stddev_exec_time double precision Population standard deviation of time spent executing the statement, in milliseconds
rows bigint Total number of rows retrieved or affected by the statement
shared_blks_hit bigint Total number of shared block cache hits by the statement
shared_blks_read bigint Total number of shared blocks read by the statement
shared_blks_dirtied bigint Total number of shared blocks dirtied by the statement
shared_blks_written bigint Total number of shared blocks written by the statement
local_blks_hit bigint Total number of local block cache hits by the statement
local_blks_read bigint Total number of local blocks read by the statement
local_blks_dirtied bigint Total number of local blocks dirtied by the statement
local_blks_written bigint Total number of local blocks written by the statement
temp_blks_read bigint Total number of temp blocks read by the statement
temp_blks_written bigint Total number of temp blocks written by the statement
blk_read_time double precision Total time the statement spent reading data file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time double precision Total time the statement spent writing data file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
temp_blk_read_time double precision

Column Type Description
Total time the statement spent reading temporary file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
temp_blk_write_time double precision Total time the statement spent writing temporary file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
wal_records bigint Total number of WAL records generated by the statement
wal_fpi bigint Total number of WAL full page images generated by the statement
wal_bytes numeric Total amount of WAL generated by the statement in bytes
jit_functions bigint Total number of functions JIT-compiled by the statement
jit_generation_time double precision Total time spent by the statement on generating JIT code, in milliseconds
jit_inlining_count bigint Number of times functions have been inlined
jit_inlining_time double precision Total time spent by the statement on inlining functions, in milliseconds
jit_optimization_count bigint Number of times the statement has been optimized
jit_optimization_time double precision Total time spent by the statement on optimizing, in milliseconds
jit_emission_count bigint Number of times code has been emitted
jit_emission_time double precision Total time spent by the statement on emitting code, in milliseconds

For security reasons, only superusers and roles with privileges of the pg_read_all_stats role are allowed to see the SQL text and queryid of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, SELECT, INSERT, UPDATE, DELETE, and MERGE) and utility commands are combined into a single pg_stat_statements entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query.

> **Note**
>
> The following details about constant replacement and queryid only apply when compute_query_id is enabled. If you use an external module instead to compute queryid, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as $1, in the pg_stat_statements display. The rest of the query text is that of the first query that had the particular queryid hash value associated with the pg_stat_statements entry.

Queries on which normalization can be applied may be observed with constant values in pg_stat_statements, especially when there is a high rate of entry deallocations. To reduce the likelihood of this hap-

pening, consider increasing `pg_stat_statements.max`. The `pg_stat_statements_info` view, discussed below in Section F.56.2, provides statistics about entry deallocations.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that `queryid` values are stable between minor version releases of PostgreSQL, providing that instances are running on the same machine architecture and the catalog metadata details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

F.56.2. The `pg_stat_statements_info` View

The statistics of the `pg_stat_statements` module itself are tracked and made available via a view named `pg_stat_statements_info`. This view contains only a single row. The columns of the view are shown in Table F.41.

Table F.41. `pg_stat_statements_info` Columns

Column Type Description
`dealloc` bigint

Column Type Description
Total number of times pg_stat_statements entries about the least-executed statements were deallocated because more distinct statements than pg_stat_statements.max were observed
stats_reset timestamp with time zone Time at which all statistics in the pg_stat_statements view were last reset.

F.56.3. Functions

pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint) returns void

pg_stat_statements_reset discards statistics gathered so far by pg_stat_statements corresponding to the specified userid, dbid and queryid. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. If all statistics in the pg_stat_statements view are discarded, it will also reset the statistics in the pg_stat_statements_info view. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

pg_stat_statements(showtext boolean) returns setof record

The pg_stat_statements view is defined in terms of a function also named pg_stat_statements. It is possible for clients to call the pg_stat_statements function directly, and by specifying showtext := false have query text be omitted (that is, the OUT argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all pg_stat_statements itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the pg_stat_statements data.

F.56.4. Configuration Parameters

pg_stat_statements.max (integer)

pg_stat_statements.max is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the pg_stat_statements view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the pg_stat_statements_info view. The default value is 5000. This parameter can only be set at server start.

pg_stat_statements.track (enum)

pg_stat_statements.track controls which statements are counted by the module. Specify top to track top-level statements (those issued directly by clients), all to also track nested statements (such as statements invoked within functions), or none to disable statement statistics collection. The default value is top. Only superusers can change this setting.

pg_stat_statements.track_utility (boolean)

pg_stat_statements.track_utility controls whether utility commands are tracked by the module. Utility commands are all those other than SELECT, INSERT, UPDATE, DELETE, and MERGE. The default value is on. Only superusers can change this setting.

pg_stat_statements.track_planning (boolean)

pg_stat_statements.track_planning controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of pg_stat_statements entries. The default value is off. Only superusers can change this setting.

`pg_stat_statements.save` (`boolean`)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

F.56.5. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

F.56.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.57. pgstattuple — obtain tuple-level statistics

The pgstattuple module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role pg_stat_scan_tables has EXECUTE privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue GRANT commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the pg_stat_scan_tables role instead.

F.57.1. Functions

```
pgstattuple(regclass) returns record
```

pgstattuple returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]------+-------
table_len          | 458752
tuple_count        | 1470
tuple_len          | 438896
tuple_percent      | 95.67
dead_tuple_count   | 11
dead_tuple_len     | 3157
dead_tuple_percent | 0.69
free_space         | 8932
free_percent       | 1.95
```

The output columns are described in Table F.42.

Table F.42. pgstattuple Output Columns

Column	Type	Description
table_len	bigint	Physical relation length in bytes
tuple_count	bigint	Number of live tuples
tuple_len	bigint	Total length of live tuples in bytes
tuple_percent	float8	Percentage of live tuples
dead_tuple_count	bigint	Number of dead tuples
dead_tuple_len	bigint	Total length of dead tuples in bytes
dead_tuple_percent	float8	Percentage of dead tuples
free_space	bigint	Total free space in bytes
free_percent	float8	Percentage of free space

> **Note**
>
> The table_len will always be greater than the sum of the tuple_len, dead_tuple_len and free_space. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

pgstattuple acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text) returns record`

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass) returns record`

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]------+------
version            | 2
tree_level         | 0
index_size         | 16384
root_block_no      | 1
internal_pages     | 0
leaf_pages         | 1
empty_pages        | 0
deleted_pages      | 0
avg_leaf_density   | 54.27
leaf_fragmentation | 0
```

The output columns are:

Column	Type	Description
`version`	`integer`	B-tree version number
`tree_level`	`integer`	Tree level of the root page
`index_size`	`bigint`	Total index size in bytes
`root_block_no`	`bigint`	Location of root page (zero if none)
`internal_pages`	`bigint`	Number of “internal” (upper-level) pages
`leaf_pages`	`bigint`	Number of leaf pages
`empty_pages`	`bigint`	Number of empty pages
`deleted_pages`	`bigint`	Number of deleted pages
`avg_leaf_density`	`float8`	Average density of leaf pages
`leaf_fragmentation`	`float8`	Leaf page fragmentation

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages + leaf_pages + empty_pages + deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text) returns record`

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass) returns record`

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+--
version        | 1
pending_pages  | 0
pending_tuples | 0
```

The output columns are:

Column	Type	Description
version	integer	GIN version number
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

`pgstathashindex(regclass) returns record`

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-----------------
version        | 4
bucket_pages   | 33081
overflow_pages | 0
bitmap_pages   | 1
unused_pages   | 32455
live_items     | 10204006
dead_items     | 0
free_percent   | 61.8005949100872
```

The output columns are:

Column	Type	Description
version	integer	HASH version number
bucket_pages	bigint	Number of bucket pages
overflow_pages	bigint	Number of overflow pages
bitmap_pages	bigint	Number of bitmap pages
unused_pages	bigint	Number of unused pages
live_items	bigint	Number of live tuples
dead_tuples	bigint	Number of dead tuples
free_percent	float	Percentage of free space

`pg_relpages(regclass) returns bigint`

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text) returns bigint`

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass) returns record`

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]--------+-------
table_len            | 573440
scanned_percent      | 2
approx_tuple_count   | 2740
approx_tuple_len     | 561210
approx_tuple_percent | 97.87
dead_tuple_count     | 0
dead_tuple_len       | 0
dead_tuple_percent   | 0
approx_free_space    | 11996
approx_free_percent  | 2.09
```

The output columns are described in Table F.43.

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates pg_class.reltuples).

Table F.43. `pgstattuple_approx` Output Columns

Column	Type	Description
`table_len`	`bigint`	Physical relation length in bytes (exact)
`scanned_percent`	`float8`	Percentage of table scanned
`approx_tuple_count`	`bigint`	Number of live tuples (estimated)
`approx_tuple_len`	`bigint`	Total length of live tuples in bytes (estimated)
`approx_tuple_percent`	`float8`	Percentage of live tuples
`dead_tuple_count`	`bigint`	Number of dead tuples (exact)
`dead_tuple_len`	`bigint`	Total length of dead tuples in bytes (exact)
`dead_tuple_percent`	`float8`	Percentage of dead tuples
`approx_free_space`	`bigint`	Total free space in bytes (estimated)
`approx_free_percent`	`float8`	Percentage of free space

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.57.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

F.58. pg_surgery — perform low-level surgery on relation data

The pg_surgery module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause UNIQUE or FOREIGN KEY constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

F.58.1. Functions

heap_force_kill(regclass, tid[]) returns void

heap_force_kill marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or directory.

test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
 heap_force_kill
-----------------

(1 row)

test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

heap_force_freeze(regclass, tid[]) returns void

heap_force_freeze marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```
test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"

test=# select ctid from t1 where xmin = 507;
 ctid
-------
 (0,3)
(1 row)

test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
 heap_force_freeze
-------------------

(1 row)

test=# select ctid from t1 where xmin = 2;
 ctid
-------
 (0,3)
(1 row)
```

Ashutosh Sharma <ashu.coek88@gmail.com>

F.59. pg_transfer — quick transfer of tables between instances

The pg_transfer extension enables quick transfer of tables between Postgres Pro Enterprise instances.

It may sometimes be required to load large volumes of data into a database, for example, when consolidating data from regional servers into a central one. If your data needs to be uploaded to a server under heavy load, you can use a temporary database on another server to accumulate the data and then transfer it all at once when the main server load is minimal.

If you use pg_dump and pg_restore applications to transfer data, the load on the receiving server is usually higher than that on the sending server. Since the data is loaded using INSERT or COPY commands, it creates a significant impact on the disk subsystem. Besides, you will have to re-build indexes in the target database once all the data is loaded, which will also contribute to the server load.

To achieve a much higher load speed for read-only data, you can use the pg_transfer extension while doing dump/restore, which allows to copy data files directly, without using COPY/INSERT commands. pg_transfer also provides auxiliary functions for pg_dump and pg_restore to transfer tables together with pre-built indexes and collected statistics, so you can avoid extra load on the target server incurred by statistics re-collection.

> **Note**
>
> Postgres Pro Enterprise configuration and the architectures of source and target servers must provide binary-compatible file formats. When restoring data, pg_transfer checks that source and target servers have the same alignment, page and segment sizes, etc.

F.59.1. Installation

pg_transfer is included into Postgres Pro Enterprise. To enable pg_transfer, create its extension in your database using the following SQL command:

```
CREATE EXTENSION pg_transfer;
```

You must create pg_transfer extension in both source and target databases.

F.59.2. Usage

To transfer data using the pg_transfer module, do the following:

1. **Prepare source and target systems for data transfer**

   Before the actual data transfer, you first need to transfer data schema to the target server:

   1. In the source database, mark the table to be transferred as read-only:

      ```
      ALTER TABLE table_name SET CONSTANT;
      ```

   2. Run the VACUUM (ANALYZE) command to remove dead tuples and refresh statistics:

      ```
      VACUUM (ANALYZE) table_name;
      ```

   3. Take a logical dump of the data schema on the source server and restore it on the target server:

      ```
      pg_dump -Fc -t table_name --schema-only -f transfer_dir/archive.out old_database
      pg_restore -d new_database --schema-only transfer_dir/archive.out
      ```

2. **Prepare TOAST identifiers for the transfer**

   This step is only required if the tables to be transferred have toasted values.

   1. Determine TOAST identifiers (*reltoastid*) in the new database:

```
psql new_database -c "SELECT reltoastrelid FROM pg_class WHERE
 relname='table_name';"
```

2. Using the received *reltoastid* identifiers, prepare the table for the transfer and force data flush to disk:

```
psql -d old_database -c "SELECT
 pg_transfer_freeze('table_name'::regclass::oid, reltoastrelid::oid);"
```

3. **Transfer the data to the target system**

1. Copy the data into a separate directory using pg_dump utility:

```
pg_dump -Fc -t table_name --transfer-dir transfer_dir/ -f transfer_dir/
archive.out old_database
```

2. Restore the data in the target database:

```
pg_restore -d new_database --data-only --transfer-dir transfer_dir/ --copy-mode-
transfer transfer_dir/archive.out
```

When source and target databases are located in the same file system, the `--copy-mode-transfer` option must be specified at least once (for either pg_dump or pg_restore command) to get an independent copy of data. When restoring data on the primary server, `--generate-wal` option must be specified for pg_restore for changes to be replicated to a standby server.

F.59.3. Compatibility

The `pg_transfer` extension is only supported on Linux systems.

Postgres Professional, Moscow, Russia

F.60. pg_trgm — support for similarity of text using trigram matching

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.60.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

> **Note**
>
> pg_trgm ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string "cat" is " c", " ca", "cat", and "at ". The set of trigrams in the string "foo|bar" is " f", " fo", "foo", "oo ", " b", " ba", "bar", and "ar ".

F.60.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F.44, the operators in Table F.45.

Table F.44. pg_trgm Functions

Function Description
similarity (text, text) → real Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
show_trgm (text) → text[] Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
word_similarity (text, text) → real Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.
strict_word_similarity (text, text) → real Same as word_similarity , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.
show_limit () → real Returns the current similarity threshold used by the % operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. (*Deprecated*; instead use SHOW pg_trgm.similarity_threshold .)
set_limit (real) → real

Function Description
Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. (*Deprecated*; instead use `SET pg_trgm.similarity_threshold` .)

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
 word_similarity
-----------------
             0.8
(1 row)
```

In the first string, the set of trigrams is `{" w"," wo","wor","ord","rd "}`. In the second string, the ordered set of trigrams is `{" t"," tw","two","wo "," w"," wo","wor","ord","rds","ds "}`. The most similar extent of an ordered set of trigrams in the second string is `{" w"," wo","wor","ord"}`, and the similarity is `0.8`.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word `'words'`, whose set of trigrams is `{" w"," wo","wor","ord","rds","ds "}`.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
 strict_word_similarity | similarity
------------------------+------------
               0.571429 |   0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

Table F.45. `pg_trgm` Operators

Operator Description
`text % text → boolean` Returns `true` if its arguments have a similarity that is greater than the current similarity threshold set by `pg_trgm.similarity_threshold` .
`text <% text → boolean` Returns `true` if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by `pg_trgm.word_similarity_threshold` parameter.
`text %> text → boolean` Commutator of the `<%` operator.
`text <<% text → boolean` Returns `true` if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the `pg_trgm.strict_word_similarity_threshold` parameter.
`text %>> text → boolean`

Operator Description
Commutator of the <<% operator.
text <-> text → real Returns the “distance” between the arguments, that is one minus the similarity() value.
text <<-> text → real Returns the “distance” between the arguments, that is one minus the word_similarity() value.
text <->> text → real Commutator of the <<-> operator.
text <<<-> text → real Returns the “distance” between the arguments, that is one minus the strict_word_similarity() value.
text <->>> text → real Commutator of the <<<-> operator.

F.60.3. GUC Parameters

pg_trgm.similarity_threshold (real)

Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

pg_trgm.word_similarity_threshold (real)

Sets the current word similarity threshold that is used by the <% and %> operators. The threshold must be between 0 and 1 (default is 0.6).

pg_trgm.strict_word_similarity_threshold (real)

Sets the current strict word similarity threshold that is used by the <<% and %>> operators. The threshold must be between 0 and 1 (default is 0.5).

F.60.4. Index Support

The pg_trgm module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for LIKE, ILIKE, ~, ~* and = queries. The similarity comparisons are case-insensitive in a default build of pg_trgm. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

gist_trgm_ops GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
  FROM test_trgm
  WHERE t % 'word'
  ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
  FROM test_trgm
  ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
  FROM test_trgm
  WHERE 'word' <% t
  ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
  FROM test_trgm
  WHERE 'word' <<% t
  ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
  FROM test_trgm
  ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
  FROM test_trgm
  ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.60.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
        ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

> **Note**
>
> Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.61. pg_tsparser — an extension for text search

pg_tsparser is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, pg_tsparser also returns the whole word.

F.61.1. Installation and Setup

pg_tsparser is included into the Postgres Pro distribution. To enable pg_tsparser, once Postgres Pro is installed, create the pg_tsparser extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once pg_tsparser is enabled, you can create your own text search configuration. In addition to pg_tsparser, you can use any available dictionary.

For example, you can create english_ts configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (
    PARSER = tsparser
);

COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for
 english language';

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,
    numhword, numword, sfloat, uint, url, url_path, version
    WITH simple;

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,
    word, hword, hword_part
    WITH english_stem;
```

F.61.2. Examples

The following examples illustrate the difference in search results returned by pg_tsparser and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,
       to_tsvector('english_ts', 'pg_trgm')  as new_parser;
   def_parser    |         new_parser
-----------------+----------------------------
 'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3
(1 row)

SELECT to_tsvector('english', '123-abc') as def_parser,
       to_tsvector('english_ts', '123-abc')  as new_parser;
   def_parser    |         new_parser
-----------------+----------------------------
 '123':1 'abc':2 | '123':2 '123-abc':1 'abc':3
(1 row)

SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,
       to_tsvector('english_ts', 'rel-3.2-A')  as new_parser;
```

```
    def_parser    |           new_parser
------------------+-------------------------------
 '-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1
(1 row)
```

F.62. pg_variables — functions for working with variables of various types

The pg_variables module provides functions for working with variables of various types. The created variables are only available in the current user session.

> **Note**
>
> This extension cannot be used while built-in connection pooling is enabled.

F.62.1. Installation

The pg_variables extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the CREATE EXTENSION command to enable pg_variables, as follows:

```
CREATE EXTENSION pg_variables;
```

F.62.2. Usage

The pg_variables module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- Section F.62.3.1 describes functions for scalar variables.
- Section F.62.3.2 describes functions for collections of record variables.
- Section F.62.3.3 describes functions for array variables.
- Section F.62.3.4 describes functions for general collection variables.
- Section F.62.3.5 describes functions for using iterators to traverse collection variables.
- Section F.62.3.6 lists functions you can use to manage all variables in your current session.

For detailed usage examples, see Section F.62.5.

F.62.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;

SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
---------+------+------------------
 vars    | int1 | f
 vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional is_transactional flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
```

```
SELECT pgv_get('vars', 'trans_int', NULL::int);
 pgv_get
---------
     101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
 package |   name    | is_transactional
---------+-----------+------------------
 pack    | var_trans | t
```

F.62.3. Functions

F.62.3.1. Scalar Variables

The following functions support scalar variables:

Function	Returns
`pgv_set(package text, name text, value anynonarray, is_transactional bool default false)`	`void`
`pgv_get(package text, name text, var_type anynonarray, strict bool default true)`	`anynonarray`

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized package "vars"

SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR:  variable "int1" requires "integer" value
```

F.62.3.2. Collections of Records

The following functions support collections of record variables:

Function	Returns	Description
`pgv_insert(package text, name text, r record, is_transactional bool default false)`	`void`	Inserts a record into a collection variable for the specified package. If the package or variable does not exist, it is created automatically. The first column of `r` is the primary key. If a record with the same primary key already exists or this collection variable has a different structure, an error is raised.
`pgv_update(package text, name text, r record)`	`boolean`	Updates a record with the corresponding primary key (the first column of `r` is the primary key). Returns `true` if the record was found. If this collection variable has a different structure, an error is raised.
`pgv_delete(package text, name text, value anynonarray)`	`boolean`	Deletes a record with the corresponding primary key (the first column of `r` is the primary key). Returns `true` if the record was found and `false` otherwise.
`pgv_select(package text, name text)`	`set of records`	Returns the collection variable records.
`pgv_select(package text, name text, value anynonarray)`	`record`	Returns the record with the corresponding primary key (the first column of `r` is a primary key).
`pgv_select(package text, name text, value anyarray)`	`set of records`	Returns the collection variable records with the corresponding primary keys (the first column of `r` is a primary key).

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

F.62.3.3. Arrays

The following functions support array variables:

Function	Returns
`pgv_set(package text, name text, value anyarray, is_transactional bool default false)`	`void`
`pgv_get(package text, name text, var_type anyarray, strict bool default true)`	`anyarray`

Usage instructions for these functions are the same as those provided in Section F.62.3.1 for scalar variables.

F.62.3.4. General Collections

The following functions support general collection variables:

Function	Returns	Description
`pgv_set_elem(package text, name text, key int, value anyelement, is_transactional bool default false)` `pgv_set_elem(package text, name text, key text, value anyelement, is_transactional bool default false)`	`void`	Sets a value for the element with the key `key` of the collection variable `name` in the package `package`. If the package or variable does not exist, it is created automatically. Inside one collection, only keys of the same type are allowed. The `key` argument can have either `int` or `text` type. If an element with the specified key already exists, its value is set to the new one. `is_transactional` shows whether the new variable is transactional and equals `false` by default. So if the variable already exists, it must be transactional/non-transactional as indicated by `is_transactional`, otherwise an error is raised. If the collection already exists and its value type does not match the type of the new value, an error is also raised.
`pgv_get_elem(package text, name text, key int, val_type anyelement)` `pgv_get_elem(package text, name text, key text, val_type anyelement)`	`anyelement`	Returns the value of the element with the key `key` of the collection variable `name` in the package `package`. If there is no element with the specified key in this collection, returns NULL. The `key` argument can have either `int` or `text` type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised. The `val_type` argument is required to properly determine the return type.
`pgv_exists_elem(package text, name text, key int)` `pgv_exists_elem(package text, name text, key text)`	`bool`	Returns `true` if an element with the key `key` exists in the collection variable `name` in the package `package` and `false` otherwise. If the package or variable does not exist, also returns `false`. The `key` argument can have either `int` or `text` type. If the specified variable is not a collection, an error is raised.
`pgv_remove_elem(package text, name text, key int)`	`void`	Removes the element with the key `key` from the collection variable `name` in the package `package`. If there is no element with

Function	Returns	Description
pgv_remove_elem(package text, name text, key text)		the specified key in this collection, does nothing. The key argument can have either int or text type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised.

Important

Collections initialized with pgv_set_elem() and with pgv_insert() are not considered compatible.

F.62.3.5. Iterators

The following functions are provided to use iterators to traverse collection variables. These functions work with collections initialized with both pgv_set_elem() and pgv_insert().

Function	Returns	Description
pgv_first(package text, name text, key_type anyelement)	anyelement	Returns the first key from the collection variable. Collections are sorted by the key in ascending order. key_type is required to determine the return value. If the name passed is the name of a non-collection variable, an error is raised.
pgv_last(package text, name text, key_type anyelement)	anyelement	Returns the last key from the collection variable. Collections are sorted by the key in ascending order. key_type is required to determine the return value. If the name passed is the name of a non-collection variable, an error is raised.
pgv_next(package text, name text, key anyelement)	anyelement	Returns the next key from the collection variable. The key passed may not exist in the collection. Returns NULL if used for the last key in the collection. Collections are sorted by the key in ascending order. If the name passed is the name of a non-collection variable, an error is raised.
pgv_prior(package text, name text, key anyelement)	anyelement	Returns the previous key from the collection variable. The key passed may not exist in the collection. Returns NULL if used for the first key in the collection. Collections are sorted by the key in ascending order. If the name passed is the name of a

Function	Returns	Description
		non-collection variable, an error is raised.
pgv_count(package text, name text)	integer	Returns the number of elements in the collection. If the name passed is the name of a non-collection variable, an error is raised.

F.62.3.6. Miscellaneous Functions

Function	Returns	Description
pgv_exists(package text, name text)	bool	Returns true if the specified package and variable exist and false otherwise.
pgv_exists(package text)	bool	Returns true if the specified package exists and false otherwise.
pgv_remove(package text, name text)	void	Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.
pgv_remove(package text)	void	Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.
pgv_free()	void	Removes all packages and variables.
pgv_list()	table(package text, name text, is_transactional bool)	Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.
pgv_stats()	table(package text, allocated_memory bigint)	Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a ROLLBACK. This function only supports Postgres Pro 9.6 or higher.

F.62.3.7. Deprecated Functions

F.62.3.7.1. Integer Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_int(package text, name text, value int, is_transactional bool default false)	void

Function	Returns
pgv_get_int(package text, name text, strict bool default true)	int

F.62.3.7.2. Text Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_text(package text, name text, value text, is_transactional bool default false)	void
pgv_get_text(package text, name text, strict bool default true)	text

F.62.3.7.3. Numeric Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)	void
pgv_get_numeric(package text, name text, strict bool default true)	numeric

F.62.3.7.4. Timestamp Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)	void
pgv_get_timestamp(package text, name text, strict bool default true)	timestamp

F.62.3.7.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_timestamptz(package text, name text, value timestamptz, is_transactional bool default false)	void
pgv_get_timestamptz(package text, name text, strict bool default true)	timestamptz

F.62.3.7.6. Date Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_date(package text, name text, value date, is_transactional bool default false)	void

Function	Returns
pgv_get_date(package text, name text, strict bool default true)	date

F.62.3.7.7. Jsonb Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)	void
pgv_get_jsonb(package text, name text, strict bool default true)	jsonb

F.62.4. Important Notes

F.62.4.1. Collations in Collections

Collections are stored in ascending order. In the case of `text` keys, you need a collation to determine the order of elements. If no collation is specified when inserting the first element of a collection, the default collation is used. Otherwise, the specified collation is used.

F.62.4.2. Cursors for Set-Returning Functions

All set-returning functions except `pgv_select(package, variable)` fix their return results at first `FETCH` from the cursor and are not affected by further data manipulation.

The results of `pgv_select(package, variable)` are received dynamically and are affected by transactions/changes in the collection. For `pgv_select()` called for a transactional collection, cursors look at the snapshot of the collection when the first `FETCH` was executed, but consider changes that were made in that transaction and in committed subtransactions.

F.62.5. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);

SELECT pgv_get('vars', 'int1', NULL::int);
 pgv_get
-------------
         101

SELECT pgv_get('vars', 'int2', NULL::int);
 pgv_get
-------------
         102

SELECT pgv_get('vars', 'text1', NULL::text);
 pgv_get
---------------
 text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;

SELECT pgv_select('vars', 'r1');
 pgv_select
------------
 (1,str11)
 (0,str00)

SELECT pgv_select('vars', 'r1', 1);
 pgv_select
------------
 (1,str11)

SELECT pgv_select('vars', 'r1', 0);
 pgv_select
------------
 (0,str00)

SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
 pgv_select
------------
 (1,str11)
 (0,str00)

SELECT pgv_delete('vars', 'r1', 1);

SELECT pgv_select('vars', 'r1');
 pgv_select
------------
 (0,str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
    pgv_get
---------------
 savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
     pgv_get
------------------
 before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
```

```
         pgv_get
-------------------------
 before transaction block
```

If you create a variable after `BEGIN` or `SAVEPOINT` statements and than rollback to the previous state, the transactional variable is removed:

```
BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
---------
     122

ROLLBACK TO sp1;
SELECT pgv_get('pack','var_int', NULL::int);
ERROR:  unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
 package |   name   | is_transactional
---------+----------+------------------
 pack    | var_text | t
 vars    | int1     | f
 vars    | int2     | f
 vars    | r1       | f
 vars    | text1    | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
 package | allocated_memory
---------+------------------
 pack    |            16384
 vars    |            32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

These examples show usage of collection variables and iterator functions:

```
sql
SELECT pgv_set_elem('pack', 'var', 1, 1);
SELECT pgv_set_elem('pack', 'var', 5, 5);
SELECT pgv_set_elem('pack', 'var', 10, 10);

SELECT pgv_first('pack', 'var', NULL::int);
 pgv_first
-----------
         1
```

```
SELECT pgv_last('pack', 'var', NULL::int);
 pgv_last
----------
       10

SELECT pgv_next('pack', 'var', pgv_first('pack', 'var', NULL::int));
 pgv_next
----------
        5

SELECT pgv_prior('pack', 'var', pgv_last('pack', 'var', NULL::int));
 pgv_prior
-----------
         5

SELECT pgv_prior('pack', 'var', pgv_first('pack', 'var', NULL::int));
 pgv_prior
-----------

SELECT pgv_next('pack', 'var', pgv_last('pack', 'var', NULL::int));
 pgv_prior
-----------

SELECT pgv_next('pack', 'var', 3);
 pgv_next
----------
        5

SELECT pgv_prior('pack', 'var', 3);
 pgv_prior
-----------
         1

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
 pgv_get_elem
--------------
           10

SELECT pgv_remove_elem('pack', 'var', pgv_last('pack', 'var', NULL::int));
 pgv_remove_elem
-----------------

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
 pgv_get_elem
--------------
           5
(1 row)
```

These examples show how the collation affects the order of elements in a collection. They also show how to iterate over a whole collection with PL/pgSQL loops:

```
sql
SELECT pgv_set_elem('pack', 'var1', 'a' COLLATE "ru_RU", 'a'::text);
SELECT pgv_set_elem('pack', 'var1', 'д' COLLATE "ru_RU", 'д'::text);
SELECT pgv_set_elem('pack', 'var1', 'e' COLLATE "ru_RU", 'e'::text);
SELECT pgv_set_elem('pack', 'var1', 'ё' COLLATE "ru_RU", 'ё'::text);
SELECT pgv_set_elem('pack', 'var1', 'ж' COLLATE "ru_RU", 'ж'::text);
SELECT pgv_set_elem('pack', 'var1', 'я' COLLATE "ru_RU", 'я'::text);
```

```
DO
$$
DECLARE
        iter text;
BEGIN
        iter := pgv_first('pack', 'var1', NULL::text);
        WHILE iter IS NOT NULL LOOP
          RAISE NOTICE '%', pgv_get_elem('pack', 'var1', iter, NULL::text);
          iter := pgv_next('pack', 'var1', iter);
        END LOOP;
END;
$$;
NOTICE:  a
NOTICE:  д
NOTICE:  e
NOTICE:  ё
NOTICE:  ж
NOTICE:  я

SELECT pgv_set_elem('pack', 'var2', 'a' COLLATE "C", 'a'::text);
SELECT pgv_set_elem('pack', 'var2', 'д' COLLATE "C", 'д'::text);
SELECT pgv_set_elem('pack', 'var2', 'e' COLLATE "C", 'e'::text);
SELECT pgv_set_elem('pack', 'var2', 'ё' COLLATE "C", 'ё'::text);
SELECT pgv_set_elem('pack', 'var2', 'ж' COLLATE "C", 'ж'::text);
SELECT pgv_set_elem('pack', 'var2', 'я' COLLATE "C", 'я'::text);
DO

F.63. pg_visibility — visibility map information and utilities

The pg_visibility module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's PD_ALL_VISIBLE bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after pg_visibility examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about PD_ALL_VISIBLE bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.63.1. Functions

pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the PD_ALL_VISIBLE bit of that block.

pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the PD_ALL_VISIBLE bit of each block.

pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint) returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

pg_check_frozen(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_check_visible(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass) returns void`

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and roles with privileges of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

Robert Haas `<rhaas@postgresql.org>`

F.64. pg_wait_sampling — collecting sampling-based statistics on wait events

pg_wait_sampling is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Enterprise provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The pg_wait_sampling extension automates wait events sampling by launching a special background worker. With pg_wait_sampling enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time (per wait event type).
- Current wait events for all processes, including background workers.

Using pg_wait_sampling, you can troubleshoot dependencies for queries that process longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see Table 28.4.

In combination with pg_stat_statements, this extension can also provide per query statistics.

See Also

Viewing Statistics on Wait Events

Reference

F.64.1. Installation

The pg_wait_sampling extension is included into Postgres Pro Enterprise and requires no special prerequisites.

To enable pg_wait_sampling, do the following:

1. Add pg_wait_sampling to the shared_preload_libraries variable in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pg_wait_sampling'
   ```

   Important

   When using the pg_wait_sampling with the pg_stat_statements extension, place pg_stat_statements before pg_wait_sampling in the shared_preload_libraries variable. This ensures that the pg_stat_statements extension does not overwrite query IDs that are used by pg_wait_sampling.

2. Create the pg_wait_sampling extension using the following query:

   ```
   CREATE EXTENSION pg_wait_sampling;
   ```

3. Restart the server. Since pg_wait_sampling requires additional shared memory and launches a background worker, you must restart the server after adding or removing pg_wait_sampling.

Once the extension is created, pg_wait_sampling starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using GUC variables.

If you want to stop collecting statistics, drop the pg_wait_sampling extension, remove the pg_wait_sampling from the shared_preload_libraries variable, and restart the server again.

F.64.2. Usage

F.64.2.1. Viewing Statistics on Wait Events

When pg_wait_sampling is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the pg_wait_sampling_current view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run pg_wait_sampling_get_current() function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the pg_wait_sampling_history view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the pg_wait_sampling.history_size variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the pg_wait_sampling_profile view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the pg_wait_sampling_reset_profile() function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

> **Important**
>
> Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the pg_wait_sampling.profile_pid variable to false. In this case, the pid value for each process is set to zero, and wait samples for all the processes are stored together.

F.64.3. Reference

F.64.3.1. GUC Variables

The pg_wait_sampling extension is configured with GUC variables. They are stored in the local memory and can be changed in the postgresql.conf file or using the ALTER SYSTEM command. For the changes to take effect, reload the server configuration. You can do it, for example, by calling the pg_reload_conf() function or executing the pg_ctl reload command.

pg_wait_sampling.history_size (int4)

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

pg_wait_sampling.history_period (int4)

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period` (`int4`)

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid` (`bool`)

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

`pg_wait_sampling.profile_queries` (`enum`)

Sampling mode for the waits profile. If `pg_wait_sampling.profile_queries` is set to `none`, the `queryid` field in views will be zero. If it is set to `top`, query IDs of only the top level statements are recorded. If it is set to `all`, query IDs of nested statements are recorded. To collect the waits profile per query, ensure that the pg_stat_statements extension is configured and set `pg_wait_sampling.profile_queries` to `top`. For version 14 or higher, you can compute query IDs by configuring the `compute_query_id` parameter and set the `pg_wait_sampling.profile_queries` value to `top` or `all`. For details, see Section 19.9.2.

Default: `top`

`pg_wait_sampling.sample_cpu` (`bool`)

The sampling mode that determines whether to perform sampling of on-CPU backends. If `pg_wait_sampling.sample_cpu` is set to `true`, then sampling also includes processes that are not waiting for anything. The wait event columns for such processes will have a `NULL` value.

Default: `true`

F.64.3.2. pg_wait_sampling Views

F.64.3.2.1. pg_wait_sampling_current View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

Table F.46. pg_wait_sampling_current View

Column Name	Column Type	Description
`pid`	`int4`	Process ID
`event_type`	`text`	Name of wait event type
`event`	`text`	Name of wait event
`queryid`	`int8`	Query ID

F.64.3.2.2. pg_wait_sampling_history View

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

Table F.47. pg_wait_sampling_history View

Column Name	Column Type	Description
`pid`	`int4`	Process ID

Column Name	Column Type	Description
ts	timestamptz	Sample timestamp
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID

F.64.3.2.3. pg_wait_sampling_profile View

The pg_wait_sampling_profile view provides the profile of wait events. This data is stored as an in-memory hash table.

Table F.48. pg_wait_sampling_profile View

Column Name	Column Type	Description
pid	int4	Process ID
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID
count	int8	Number of samples

F.64.3.3. Functions

pg_wait_sampling_get_current(*pid* int4)

Returns the pg_wait_sampling_current view with the list of current wait events. If you set the *pid* argument, the view is filtered for the process with this *pid*.

Arguments:

- *pid* — Optional. The process ID for which to display the current wait events.

pg_wait_sampling_reset_profile()

Resets the waits profile and clears the memory.

- Alexander Korotkov
- Ildus Kurbangaliev <i.kurbangaliev@gmail.com>

F.65. pg_walinspect — low-level WAL inspection

The pg_walinspect module provides SQL functions that allow you to inspect the contents of write-ahead log of a running Postgres Pro database cluster at a low level, which is useful for debugging, analytical, reporting or educational purposes. It is similar to pg_waldump, but accessible through SQL rather than a separate utility.

All the functions of this module will provide the WAL information using the server's current timeline ID.

> **Note**
>
> The pg_walinspect functions are often called using an LSN argument that specifies the location at which a known WAL record of interest *begins*. However, some functions, such as pg_logical_emit_message, return the LSN *after* the record that was just inserted.

> **Tip**
>
> All of the pg_walinspect functions that show information about records that fall within a certain LSN range are permissive about accepting *end_lsn* arguments that are after the server's current LSN. Using an *end_lsn* "from the future" will not raise an error.
>
> It may be convenient to provide the value FFFFFFFF/FFFFFFFF (the maximum valid pg_lsn value) as an *end_lsn* argument. This is equivalent to providing an *end_lsn* argument matching the server's current LSN.

By default, use of these functions is restricted to superusers and members of the pg_read_server_files role. Access may be granted by superusers to others using GRANT.

F.65.1. General Functions

pg_get_wal_record_info(in_lsn pg_lsn) returns record

Gets WAL record information about a record that is located at or after the *in_lsn* argument. For example:

```
postgres=# SELECT * FROM pg_get_wal_record_info('0/E419E28');
-[ RECORD 1 ]----+-----------------------------------------------
start_lsn        | 0/E419E28
end_lsn          | 0/E419E68
prev_lsn         | 0/E419D78
xid              | 0
resource_manager | Heap2
record_type      | VACUUM
record_length    | 58
main_data_length | 2
fpi_length       | 0
description      | nunused: 5, unused: [1, 2, 3, 4, 5]
block_ref        | blkref #0: rel 1663/16385/1249 fork main blk 364
```

If *in_lsn* isn't at the start of a WAL record, information about the next valid WAL record is shown instead. If there is no next valid WAL record, the function raises an error.

pg_get_wal_records_info(start_lsn pg_lsn, end_lsn pg_lsn) returns setof record

Gets information of all the valid WAL records between *start_lsn* and *end_lsn*. Returns one row per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_records_info('0/1E913618', '0/1E913740') LIMIT
 1;
```

```
-[ RECORD 1 ]----+-----------------------------------------------------------
start_lsn        | 0/1E913618
end_lsn          | 0/1E913650
prev_lsn         | 0/1E9135A0
xid              | 0
resource_manager | Standby
record_type      | RUNNING_XACTS
record_length    | 50
main_data_length | 24
fpi_length       | 0
description      | nextXid 33775 latestCompletedXid 33774 oldestRunningXid 33775
block_ref        |
```

The function raises an error if *start_lsn* is not available.

```
pg_get_wal_block_info(start_lsn pg_lsn, end_lsn pg_lsn, show_data boolean DEFAULT true)
returns setof record
```

Gets information about each block reference from all the valid WAL records between *start_lsn* and *end_lsn* with one or more block references. Returns one row per block reference per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_block_info('0/1230278', '0/12302B8');
-[ RECORD 1 ]-----+----------------------------------
start_lsn         | 0/1230278
end_lsn           | 0/12302B8
prev_lsn          | 0/122FD40
block_id          | 0
reltablespace     | 1663
reldatabase       | 1
relfilenode       | 2658
relforknumber     | 0
relblocknumber    | 11
xid               | 341
resource_manager  | Btree
record_type       | INSERT_LEAF
record_length     | 64
main_data_length  | 2
block_data_length | 16
block_fpi_length  | 0
block_fpi_info    |
description       | off: 46
block_data        | \x00002a000700104026300000070696400
block_fpi_data    |
```

This example involves a WAL record that only contains one block reference, but many WAL records contain several block references. Rows output by `pg_get_wal_block_info` are guaranteed to have a unique combination of *start_lsn* and *block_id* values.

Much of the information shown here matches the output that `pg_get_wal_records_info` would show, given the same arguments. However, `pg_get_wal_block_info` unnests the information from each WAL record into an expanded form by outputting one row per block reference, so certain details are tracked at the block reference level rather than at the whole-record level. This structure is useful with queries that track how individual blocks changed over time. Note that records with no block references (e.g., `COMMIT` WAL records) will have no rows returned, so `pg_get_wal_block_info` may actually return *fewer* rows than `pg_get_wal_records_info`.

The `reltablespace`, `reldatabase`, and `relfilenode` parameters reference `pg_tablespace.oid`, `pg_database.oid`, and `pg_class.relfilenode` respectively. The `relforknumber` field is the fork number within the relation for the block reference; see `common/relpath.h` for details.

> **Tip**
>
> The `pg_filenode_relation` function (see Table 9.98) can help you to determine which relation was modified during original execution.

It is possible for clients to avoid the overhead of materializing block data. This may make function execution significantly faster. When *`show_data`* is set to `false`, `block_data` and `block_fpi_data` values are omitted (that is, the `block_data` and `block_fpi_data OUT` arguments are `NULL` for all rows returned). Obviously, this optimization is only feasible with queries where block data isn't truly required.

The function raises an error if *`start_lsn`* is not available.

```
pg_get_wal_stats(start_lsn pg_lsn, end_lsn pg_lsn, per_record boolean DEFAULT false)
returns setof record
```

Gets statistics of all the valid WAL records between *`start_lsn`* and *`end_lsn`*. By default, it returns one row per *`resource_manager`* type. When *`per_record`* is set to `true`, it returns one row per *`record_type`*. For example:

```
postgres=# SELECT * FROM pg_get_wal_stats('0/1E847D00', '0/1E84F500')
           WHERE count > 0 AND
                 "resource_manager/record_type" = 'Transaction'
           LIMIT 1;
-[ RECORD 1 ]----------------+-------------------
resource_manager/record_type | Transaction
count                        | 2
count_percentage             | 8
record_size                  | 875
record_size_percentage       | 41.23468426013195
fpi_size                     | 0
fpi_size_percentage          | 0
combined_size                | 875
combined_size_percentage     | 2.8634072910530795
```

The function raises an error if *`start_lsn`* is not available.

F.66. plantuner — hints for the planner to disable or enable indexes for query execution

The plantuner module provides hints for the planner that can disable or enable indexes for query execution.

F.66.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of plantuner provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the plantuner.fix_empty_table GUC variable is set to true, plantuner sets to zero the number of pages/tuples of the table that has no blocks in a file.

F.66.2. GUC Variables

plantuner.disable_index — list of indexes invisible to planner.

plantuner.enable_index — list of indexes visible to planner even if they are hidden by plantuner.disable_index.

F.66.3. Example

To enable the module, you can either load plantuner shared library in a psql session or specify shared_preload_libraries option in postgresql.conf.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
     Table "public.test"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
                              QUERY PLAN
-----------------------------------------------------------------------
 Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
   Recheck Cond: (id = 1)
   ->  Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
         Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
                              QUERY PLAN
-----------------------------------------------------------------------
 Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
   Recheck Cond: (id = 1)
   ->  Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
         Index Cond: (id = 1)
```

```
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
                              QUERY PLAN
-----------------------------------------------------------------------
 Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
   Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
                             QUERY PLAN
--------------------------------------------------------------------
 Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
   Recheck Cond: (id = 1)
   ->  Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
         Index Cond: (id = 1)
(4 rows)
```

F.67. postgres_fdw — access data stored in external Postgres Pro servers

The postgres_fdw module provides the foreign-data wrapper postgres_fdw, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older dblink module. But postgres_fdw provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using postgres_fdw:

1. Install the postgres_fdw extension using CREATE EXTENSION.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want to connect to. Specify connection information, except user and password, as options of the server object.
3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as user and password options of the user mapping.
4. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only SELECT from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using INSERT, UPDATE, DELETE, COPY, or TRUNCATE. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the ONLY option specified in SELECT, UPDATE, DELETE or TRUNCATE has no effect when accessing or modifying the remote table.

Note that postgres_fdw currently lacks support for INSERT statements with an ON CONFLICT DO UPDATE clause. However, the ON CONFLICT DO NOTHING clause is supported, provided a unique index inference specification is omitted. Note also that postgres_fdw supports row movement invoked by UPDATE statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an UPDATE target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although postgres_fdw is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.67.1. FDW Options of postgres_fdw

F.67.1.1. Connection Options

A foreign server using the postgres_fdw foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 37.1.2, except that these options are not allowed or have special handling:

- user, password and sslpassword (specify these in a user mapping, instead, or use a service file)
- client_encoding (this is automatically set from the local server encoding)
- application_name - this may appear in *either or both* a connection and postgres_fdw.application_name. If both are present, postgres_fdw.application_name overrides the connection setting.

Unlike libpq, postgres_fdw allows application_name to include “escape sequences”. See postgres_fdw.application_name for details.

- fallback_application_name (always set to postgres_fdw)
- sslkey and sslcert - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the sslcert or sslkey settings.

Non-superusers may connect to foreign servers using password authentication or with GSSAPI delegated credentials, so specify the password option for user mappings belonging to non-superusers where password authentication is required.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option password_required 'false', e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set password_required=false on the public role. Keep in mind that the mapped user can potentially use any client certificates, .pgpass, .pg_service.conf etc. in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like peer or ident authentication.

F.67.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

schema_name (string)

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

table_name (string)

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

column_name (string)

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.67.1.3. Cost Estimation Options

postgres_fdw retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So postgres_fdw provides the following options to control how cost estimation is done:

use_remote_estimate (boolean)

This option, which can be specified for a foreign table or a foreign server, controls whether postgres_fdw issues remote EXPLAIN commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is false.

`fdw_startup_cost` (`floating point`)

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is `100`.

`fdw_tuple_cost` (`floating point`)

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is `0.01`.

When `use_remote_estimate` is true, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is false, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running ANALYZE on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

The following option controls how such an `ANALYZE` operation behaves:

`analyze_sampling` (`string`)

This option, which can be specified for a foreign table or a foreign server, determines if `ANALYZE` on a foreign table samples the data on the remote side, or reads and transfers all data and performs the sampling locally. The supported values are `off`, `random`, `system`, `bernoulli` and `auto`. `off` disables remote sampling, so all data are transferred and sampled locally. `random` performs remote sampling using the `random()` function to choose returned rows, while `system` and `bernoulli` rely on the built-in `TABLESAMPLE` methods of those names. `random` works on all remote server versions, while `TABLESAMPLE` is supported only since 9.5. `auto` (the default) picks the recommended sampling method automatically; currently it means either `bernoulli` or `random` depending on the remote server version.

F.67.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions` (`string`)

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size` (`integer`)

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is `100`.

batch_size (integer)

This option specifies the number of rows postgres_fdw should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows postgres_fdw inserts at once depends on the number of columns and the provided batch_size value. The batch is executed as a single query, and the libpq protocol (which postgres_fdw uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns * batch_size exceeds the limit, the batch_size will be adjusted to avoid an error.

This option also applies when copying into foreign tables. In that case the actual number of rows postgres_fdw copies at once is determined in a similar way to the insert case, but it is limited to at most 1000 due to implementation restrictions of the COPY command.

F.67.1.5. Asynchronous Execution Options

postgres_fdw supports asynchronous execution, which runs multiple parts of an Append node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

async_capable (boolean)

This option controls whether postgres_fdw allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is false.

In order to ensure that the data being returned from a foreign server is consistent, postgres_fdw will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an Append node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using postgres_fdw, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

F.67.1.6. Transaction Management Options

As described in the Transaction Management section, in postgres_fdw transactions are managed by creating corresponding remote transactions, and subtransactions are managed by creating corresponding remote subtransactions. When multiple remote transactions are involved in the current local transaction, by default postgres_fdw commits or aborts those remote transactions serially when the local transaction is committed or aborted. When multiple remote subtransactions are involved in the current local subtransaction, by default postgres_fdw commits or aborts those remote subtransactions serially when the local subtransaction is committed or aborted. Performance can be improved with the following options:

parallel_commit (boolean)

This option controls whether postgres_fdw commits, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is committed. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is false.

parallel_abort (boolean)

This option controls whether postgres_fdw aborts, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is aborted. This setting also applies

to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

If multiple foreign servers with these options enabled are involved in a local transaction, multiple remote transactions on those foreign servers are committed or aborted in parallel across those foreign servers when the local transaction is committed or aborted.

When these options are enabled, a foreign server with many remote transactions may see a negative performance impact when the local transaction is committed or aborted.

F.67.1.7. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable` (`boolean`)

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.67.1.8. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

`truncatable` (`boolean`)

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

F.67.1.9. Importing Options

`postgres_fdw` is able to import foreign table definitions using IMPORT FOREIGN SCHEMA. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate` (`boolean`)

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default` (`boolean`)

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated` (`boolean`)

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null` (`boolean`)

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see CREATE FOREIGN TABLE.

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from IMPORT FOREIGN SCHEMA. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

F.67.1.10. Connection Management Options

By default, all connections that `postgres_fdw` establishes to foreign servers are kept open in the local session for re-use.

`keep_connections` (`boolean`)

This option controls whether `postgres_fdw` keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is `on`. If set to `off`, all connections to this foreign server will be discarded at the end of each transaction.

F.67.2. Functions

`postgres_fdw_get_connections(OUT server_name text, OUT valid boolean) returns setof record`

This function returns the foreign server names of all the open connections that `postgres_fdw` established from the local session to the foreign servers. It also returns whether each connection is valid or not. `false` is returned if the foreign server connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be `NULL` if the server is dropped), and then such invalid connection will be closed at the end of that transaction. `true` is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

```
postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
 server_name | valid
-------------+-------
 loopback1   | t
```

```
 loopback2   | f
```

`postgres_fdw_disconnect(server_name text) returns boolean`

This function discards the open connections that are established by `postgres_fdw` from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect('loopback1');
 postgres_fdw_disconnect
-------------------------
 t
```

`postgres_fdw_disconnect_all() returns boolean`

This function discards all the open connections that are established by `postgres_fdw` from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect_all();
 postgres_fdw_disconnect_all
-----------------------------
 t
```

F.67.3. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using `keep_connections` option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

F.67.4. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ`

isolation level, but it might be surprising for a READ COMMITTED local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by postgres_fdw to prepare the remote transaction for two-phase commit.

F.67.5. Remote Query Optimization

postgres_fdw attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query WHERE clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, WHERE clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's extensions option. Operators and functions in such clauses must be IMMUTABLE as well. For an UPDATE or DELETE query, postgres_fdw attempts to optimize the query execution by sending the whole query to the remote server if there are no query WHERE clauses that cannot be sent to the remote server, no local joins for the query, no row-level local BEFORE or AFTER triggers or stored generated columns on the target table, and no CHECK OPTION constraints from parent views. In UPDATE, expressions to assign to target columns must use only built-in data types, IMMUTABLE operators, or IMMUTABLE functions, to reduce the risk of misexecution of the query.

When postgres_fdw encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the JOIN clauses, it takes the same precautions as mentioned above for the WHERE clauses.

The query that is actually sent to the remote server for execution can be examined using EXPLAIN VERBOSE.

F.67.6. Remote Query Execution Environment

In the remote sessions opened by postgres_fdw, the search_path parameter is set to just pg_catalog, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by postgres_fdw itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach SET search_path options (see CREATE FUNCTION) to such functions to establish their expected search path environment.

postgres_fdw likewise establishes remote session settings for various parameters:

- TimeZone is set to UTC
- DateStyle is set to ISO
- IntervalStyle is set to postgres
- extra_float_digits is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than search_path, but can be handled with function SET options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause postgres_fdw to malfunction.

F.67.7. Cross-Version Compatibility

postgres_fdw can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that postgres_fdw generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a WHERE clause for a foreign table. Thus, a built-in function that was added since the remote server's

release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-SELECT with OFFSET 0 as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

F.67.8. Configuration Parameters

postgres_fdw.application_name (string)

Specifies a value for application_name configuration parameter used when postgres_fdw establishes a connection to a foreign server. This overrides application_name option of the server object. Note that change of this parameter doesn't affect any existing connections until they are re-established.

postgres_fdw.application_name can be any string of any length and contain even non-ASCII characters. However when it's passed to and used as application_name in a foreign server, note that it will be truncated to less than NAMEDATALEN characters. Anything other than printable ASCII characters are replaced with C-style hexadecimal escapes. See application_name for details.

% characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the application name. Note that it's not allowed to specify a plus/minus sign or a numeric literal after the % and before the option, for alignment and padding.

Escape	Effect
%a	Application name on local server
%c	Session ID on local server (see log_line_prefix for details)
%C	Cluster name on local server (see cluster_name for details)
%u	User name on local server
%d	Database name on local server
%p	Process ID of backend on local server
%%	Literal %

For example, suppose user local_user establishes a connection from database local_db to foreign_db as user foreign_user, the setting 'db=%d, user=%u' is replaced with 'db=local_db, user=local_user'.

F.67.9. Examples

Here is an example of creating a foreign table with postgres_fdw. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using CREATE SERVER. In this example we wish to connect to a Postgres Pro server on host 192.83.123.89 listening on port 5432. The database to which the connection is made is named foreign_db on the remote server:

```
CREATE SERVER foreign_server
        FOREIGN DATA WRAPPER postgres_fdw
        OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with CREATE USER MAPPING, is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
        SERVER foreign_server
        OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with CREATE FOREIGN TABLE. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
        id integer NOT NULL,
        data text
)
        SERVER foreign_server
        OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

F.68. ptrack — a block-level incremental backup engine for Postgres Pro

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like pg_probackup can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

F.68.1. Setting up PTRACK

Once you complete Postgres Pro Enterprise installation, do the following:

1. Add `ptrack` to the shared_preload_libraries parameter in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'ptrack'
   ```

2. Set ptrack.map_size parameter to a positive integer.

   For optimal performance, it is recommended to set `ptrack.map_size` to *`N / 1024`*, where *`N`* is the size of the Postgres Pro cluster, in `MB`. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

   Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3 MB` of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with *`N`* > 1 `TB`, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the wal_level setting. When using PTRACK, it is required to set the wal_level parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.

4. Restart the Postgres Pro Enterprise instance for the changes to take effect, and then create the PTRACK extension:

   ```
   CREATE EXTENSION ptrack;
   ```

   As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

> **Note**
>
> The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

F.68.2. PTRACK Configuration Parameters

`ptrack.map_size` (`integer`)

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in `MB`. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The 0 value disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: 0

F.68.3. PTRACK Functions

`ptrack_init_lsn() returns pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(`*`start_lsn`* `pg_lsn) returns setof record`

Returns a list of data files changed since the specified *`start_lsn`* with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset('0/185C8C0');
        path         | pagecount |                pagemap
---------------------+-----------+----------------------------------------
 base/16384/1255     |         3 | \x0010000000050000000000
 base/16384/2674     |         3 | \x00000009000100000000000000000
 base/16384/2691     |         1 | \x00004000000000000000000000
 base/16384/2608     |         1 | \x000000000000000040000000000000000000
 base/16384/2690     |         1 | \x00040000000000000000000
```

`ptrack_get_change_stat(`*`start_lsn`* `pg_lsn) returns record`

Returns the statistics of changes (number of files, number of changed pages and their total size in `MB`) since the specified *`start_lsn`*.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat('0/285C8C8');
 files | pages |        size, MB
-------+-------+------------------------
    20 |    25 | 0.19531250000000000000
```

`ptrack_version() returns text`

Returns PTRACK version.

F.69. referee — manage quorum settings with an even number of nodes configured with multimaster

`referee` is a Postgres Pro Enterprise extension for managing quorum settings in clusters with an even number of nodes configured with multimaster. Installed on a separate system, the `referee` extension provides a voting node to assign the quorum status to a subset of nodes if only half of the cluster nodes remain connected to each other.

If a multi-master cluster is split into equal parts, or half of the cluster nodes fail, each subset of nodes that equals half of the cluster tries to access the referee. The first subset that gets connected to the referee wins the voting and continues working, while all the other nodes are excluded from the cluster to avoid split-brain problems.

The referee node does not store any cluster data, so it is very lightweight and can be located on systems with limited resources. For details on how to set up and use a referee node with `multimaster`, see Section F.37.3.3.

F.70. rum — an access method to work with the RUM indexes

F.70.1. Introduction

The **rum** module provides access method to work with the RUM indexes. It is based on the GIN access method code.

GIN index allows you to perform fast full-text search using tsvector and tsquery types. However, full-text search with GIN index has some performance issues because positional and other additional information is not stored.

RUM solves these issues by storing additional information in a posting tree. As compared to GIN, RUM index has the following benefits:

- Faster ranking. Ranking requires positional information. And after the index scan we do not need an additional heap scan to retrieve lexeme positions because RUM index stores them.
- Faster phrase search. This improvement is related to the previous one as phrase search also needs positional information.
- Faster ordering by timestamp. RUM index stores additional information together with lexemes, so it is not necessary to perform a heap scan.
- A possibility to perform depth-first search and therefore return first results immediately.

The drawback of RUM is that it has slower build and insert time as compared to GIN because RUM stores additional information together with keys and uses generic WAL records.

F.70.2. Installation

rum is a Postgres Pro Enterprise extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

F.70.3. Common Operators

The operators provided by the rum module are shown in Table F.49:

Table F.49. rum Operators

Operator	Returns	Description
tsvector <=> tsquery	float4	Returns distance between tsvector and tsquery values.
timestamp <=> timestamp	float8	Returns distance between two timestamp values.
timestamp <=| timestamp	float8	Returns distance only for ascending timestamp values.
timestamp |=> timestamp	float8	Returns distance only for descending timestamp values.

> **Note**
>
> rum introduces its own ranking function that is executed inside the <=> operator. It calculates the score (inverted distance) using the specified normalization method. This function is a combination of ts_rank and ts_rank_cd (see Section 9.13 for details). While ts_rank does not support logical

operators and ts_rank_cd works poorly with OR queries, the rum-specific ranking function overcomes these drawbacks.

F.70.4. Operator Classes

The rum extension provides the following operator classes:

rum_tsvector_ops

Stores tsvector lexemes with positional information. Supports ordering by <=> operator and prefix search.

rum_tsvector_hash_ops

Stores hash of tsvector lexemes with positional information. Supports ordering by <=> operator, but does not support prefix search.

rum_tsvector_addon_ops

Stores tsvector lexemes with additional data of any type supported by RUM.

> **Note**
>
> To use the rum_tsvector_addon_ops operator class, when creating the RUM index with CREATE INDEX, specify the attach and to storage parameters in the WITH clause.

rum_tsvector_hash_addon_ops

Stores tsvector lexemes with additional data of any type supported by RUM. Does not support prefix search.

rum_tsquery_ops

Stores branches of query tree in additional information.

rum_anyarray_ops

Stores anyarray elements with length of the array. Supports ordering by **<=>** operator.

Indexable operators: && @> <@ = %

rum_anyarray_addon_ops

Stores anyarray elements with additional data of any type supported by RUM.

rum_*type*_ops

Stores lexemes of the corresponding type with positional information. The *type* placeholder in the class name must be substituted by one of the following type names: int2, int4, int8, float4, float8, money, oid, timestamp, timestamptz, time, timetz, date, interval, macaddr, inet, cidr, text, varchar, char, bytea, bit, varbit, numeric.

rum_*type*_ops supports ordering by <=>, <=|, and |=> operators. This operator class can be used together with rum_tsvector_addon_ops, rum_tsvector_hash_addon_ops, and rum_anyarray_addon_ops operator classes.

Supported indexable operators depend on the data type:

- < <= = >= > <=> <=| |=> are supported for int2, int4, int8, float4, float8, money, oid, timestamp, timestamptz.

- `< <= = >= >` are supported for `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

> **Note**
>
> The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestamptz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestamptz_ops`.

F.70.5. Examples

F.70.5.1. rum_tsvector_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
    FROM test_rum
    WHERE a @@ to_tsquery('english', 'beautiful | place')
    ORDER BY a <=> to_tsquery('english', 'beautiful | place');
                t                |   rank
---------------------------------+-----------
 The situation is most beautiful | 0.0303964
 It is a beautiful               | 0.0303964
 It looks like a beautiful place | 0.0607927
(3 rows)

SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
    FROM test_rum
    WHERE a @@ to_tsquery('english', 'place | situation')
    ORDER BY a <=> to_tsquery('english', 'place | situation');
                t                |   rank
---------------------------------+-----------
 The situation is most beautiful | 0.0303964
 It looks like a beautiful place | 0.0303964
(2 rows)
```

F.70.5.2. rum_tsvector_addon_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'
```

```
CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
    WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
    SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
 <=> '2016-05-16 14:21:25' LIMIT 5;
                                    QUERY PLAN
-------------------------------------------------------------------------------
 Limit
   ->  Index Scan using tsts_idx on tsts
         Index Cond: (t @@ '''wr'' & ''qh'''::tsquery)
         Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp without time zone)
(4 rows)

SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d <=>
 '2016-05-16 14:21:25' LIMIT 5;
 id  |                d                |   ?column?
-----+---------------------------------+---------------
 355 | Mon May 16 14:21:22.326724 2016 |      2.673276
 354 | Mon May 16 13:21:22.326724 2016 |   3602.673276
 371 | Tue May 17 06:21:22.326724 2016 |  57597.326724
 406 | Wed May 18 17:21:22.326724 2016 | 183597.326724
 415 | Thu May 19 02:21:22.326724 2016 | 215997.326724
(5 rows)
```

F.70.5.3. rum_tsquery_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
    ('black', 'color'),
    ('big & bang & black & hole', 'bang'),
    ('spiral & galaxy', 'shape'),
    ('black & hole', 'color');

CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
    WHERE to_tsvector('black holes never exists before we think about them') @@ q;
        q         |  tag
------------------+-------
 'black'          | color
 'black' & 'hole' | color
(2 rows)
```

F.70.5.4. rum_anyarray_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
 ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
                QUERY PLAN
------------------------------------------
 Index Scan using idx_array on test_array
   Index Cond: (i && '{1}'::smallint[])
   Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
     i
-----------
 {1}
 {1,2}
 {1,2,3}
 {1,2,3,4}
(4 rows)
```

F.71. seg — a datatype for line segments or floating point intervals

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered "trusted", that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.71.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
 pH
---
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
          pH
------------
6.25 .. 6.50
(1 row)
```

F.71.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F.50 gives an overview of allowed representations; Table F.51 shows some examples.

In Table F.50, *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

Table F.50. `seg` External Representations

x	Single value (zero-length interval)

x `..` *y*	Interval from *x* to *y*
x `(+-)` *delta*	Interval from *x* - *delta* to *x* + *delta*
x `..`	Open interval with lower bound *x*
`..` *x*	Open interval with upper bound *x*

Table F.51. Examples of Valid `seg` Input

`5.0`	Creates a zero-length segment (a point, if you will)
`~5.0`	Creates a zero-length segment and records `~` in the data. `~` is ignored by `seg` operations, but is preserved as a comment.
`<5.0`	Creates a point at 5.0. `<` is ignored but is preserved as a comment.
`>5.0`	Creates a point at 5.0. `>` is ignored but is preserved as a comment.
`5(+-)0.3`	Creates an interval `4.7 .. 5.3`. Note that the `(+-)` notation isn't preserved.
`50 ..`	Everything that is greater than or equal to 50
`.. 0`	Everything that is less than or equal to 0
`1.5e-2 .. 2E-2`	Creates an interval `0.015 .. 0.02`
`1 ... 2`	The same as `1...2`, or `1 .. 2`, or `1..2` (spaces around the range operator are ignored)

Because the `...` operator is widely used in data sources, it is allowed as an alternative spelling of the `..` operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in `0...23` is meant to be `23` or `0.23`. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example `5 .. 2`.

F.71.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.71.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in Table F.52.

Table F.52. Seg GiST Operators

Operator **Description**
`seg << seg → boolean` Is the first `seg` entirely to the left of the second? [a, b] << [c, d] is true if b < c.
`seg >> seg → boolean` Is the first `seg` entirely to the right of the second? [a, b] >> [c, d] is true if a > d.
`seg &< seg → boolean` Does the first `seg` not extend to the right of the second? [a, b] &< [c, d] is true if b <= d.

Operator Description
`seg &> seg` → `boolean` Does the first `seg` not extend to the left of the second? [a, b] &> [c, d] is true if a >= c.
`seg = seg` → `boolean` Are the two `seg`s equal?
`seg && seg` → `boolean` Do the two `seg`s overlap?
`seg @> seg` → `boolean` Does the first `seg` contain the second?
`seg <@ seg` → `boolean` Is the first `seg` contained in the second?

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

F.71.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
---------
9.0 .. 11             -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

F.71.6. Credits

Original author: Gene Selkov, Jr. `<selkovjr@mcs.anl.gov>`, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (*https://dsf.berkeley.edu/jmh/*) for elucidating the gist of the GiST (*http://gist.cs.berkeley.edu/*). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

F.72. shared_ispell — a shared ispell dictionary

The shared_ispell module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

F.72.1. Functions

The functions provided by the shared_ispell module are shown in Table F.53.

Table F.53. shared_ispell Functions

Function	Returns	Description
shared_ispell_reset()	void	Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.
shared_ispell_mem_used()	int	Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.
shared_ispell_mem_available()	int	Returns a value of available memory of the shared segment.
shared_ispell_dicts()	setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)	Returns a list of dictionaries loaded in the shared segment.
shared_ispell_stoplists()	setof(stop_name varchar, words int, bytes int)	Returns a list of stopwords loaded in the shared segment.

F.72.2. GUC Parameters

shared_ispell.max_size (int)

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

F.72.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the shared_ispell_mem_used() function to find out how much memory was actually used (and set the shared_ispell.max_size GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC max_size limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
    ( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                      word, hword, hword_part
    WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
   alias   |   description   |   token   |         dictionaries          |   dictionary
   |  lexemes
-----------+-----------------+-----------+-------------------------------
+----------------+-----------
 asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
 english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                      word, hword, hword_part
    WITH english_shared, english_stem;
```

F.73. spi — Server Programming Interface features/examples

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.73.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in `refint.example`.

F.73.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

F.73.3. insert_username — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

F.73.4. moddatetime — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

F.74. sslinfo — obtain client SSL information

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

F.74.1. Functions Provided

`ssl_is_used() returns boolean`

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version() returns text`

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

`ssl_cipher() returns text`

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present() returns boolean`

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial() returns numeric`

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn() returns text`

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn() returns text`

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text) returns text`

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text) returns text`

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info() returns setof record`

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

F.75. tablefunc — functions that return tables (crosstab and others)

The tablefunc module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.75.1. Functions Provided

Table F.54 summarizes the functions provided by the tablefunc module.

Table F.54. tablefunc Functions

Function Description
normal_rand (*numvals* integer, *mean* float8, *stddev* float8) → setof float8 Produces a set of normally distributed random values.
crosstab (*sql* text) → setof record Produces a "pivot table" containing row names plus *N* value columns, where *N* is determined by the row type specified in the calling query.
crosstab*N* (*sql* text) → setof table_crosstab_ *N* Produces a "pivot table" containing row names plus *N* value columns. crosstab2, crosstab3, and crosstab4 are predefined, but you can create additional crosstab*N* functions as described below.
crosstab (*source_sql* text, *category_sql* text) → setof record Produces a "pivot table" with the value columns specified by a second query.
crosstab (*sql* text, *N* integer) → setof record Obsolete version of crosstab(text) . The parameter *N* is now ignored, since the number of value columns is always determined by the calling query.
connectby (*relname* text, *keyid_fld* text, *parent_keyid_fld* text [, *orderby_fld* text], *start_with* text, *max_depth* integer [, *branch_delim* text]) → setof record Produces a representation of a hierarchical tree structure.

F.75.1.1. normal_rand

```
normal_rand(int numvals, float8 mean, float8 stddev) returns setof float8
```

normal_rand produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
     normal_rand
---------------------
     1.56556322244898
     9.10040991424657
     5.36957140345079
   -0.369151492880995
    0.283600703686639
```

```
        .
        .
        .
     4.82992125404908
     9.71308014517282
     2.49639286969028
(1000 rows)
```

F.75.1.2. crosstab(text)

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce "pivot" displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11   val12   val13   ...
row2    val21   val22   val23   ...
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The *`sql`* parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. *`N`* is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

```
 row_name    cat    value
----------+-------+-------
  row1      cat1    val1
  row1      cat2    val2
  row1      cat3    val3
  row1      cat4    val4
  row2      cat1    val5
  row2      cat2    val6
  row2      cat3    val7
  row2      cat4    val8
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
           <== value  columns  ==>
 row_name   category_1   category_2
----------+------------+------------
  row1        val1         val2
```

```
  row2        val5        val6
```

The FROM clause must define the output as one row_name column (of the same data type as the first result column of the SQL query) followed by N value columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The crosstab function produces one output row for each consecutive group of input rows with the same row_name value. It fills the output value columns, left to right, with the value fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify ORDER BY 1,2 to ensure that the input rows are properly ordered, that is, values with the same row_name are brought together and correctly ordered within the row. Notice that crosstab itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);

 row_name | category_1 | category_2 | category_3
----------+------------+------------+------------
 test1    | val2       | val3       |
 test2    | val6       | val7       |
(2 rows)
```

You can avoid always having to write out a FROM clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required FROM clause in a view definition.

> **Note**
>
> See also the \crosstabview command in psql, which provides functionality similar to crosstab().

F.75.1.3. crosstabN(text)

```
crosstabN(text sql)
```

The crosstabN functions are examples of how to set up custom wrappers for the general crosstab function, so that you need not write out column names and types in the calling SELECT query. The tablefunc module includes crosstab2, crosstab3, and crosstab4, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
        .
        .
        .
    category_N TEXT
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *
FROM crosstab3(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab` C function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

  ```
  CREATE TYPE my_crosstab_float8_5_cols AS (
      my_row_name text,
      my_category_1 float8,
      my_category_2 float8,
      my_category_3 float8,
      my_category_4 float8,
      my_category_5 float8
  );

  CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
      RETURNS setof my_crosstab_float8_5_cols
      AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
  ```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

  ```
  CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
      IN text,
      OUT my_row_name text,
      OUT my_category_1 float8,
      OUT my_category_2 float8,
      OUT my_category_3 float8,
      OUT my_category_4 float8,
      OUT my_category_5 float8)
    RETURNS setof record
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
  ```

F.75.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, *`source_sql`* might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;

 row_name    extra_col   cat    value
----------+------------+-----+---------
  row1         extra1    cat1    val1
  row1         extra1    cat2    val2
  row1         extra1    cat4    val4
  row2         extra2    cat1    val5
  row2         extra2    cat2    val6
  row2         extra2    cat3    val7
  row2         extra2    cat4    val8
```

`category_sql` is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. *`category_sql`* might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
    cat
  -------
    cat1
    cat2
    cat3
    cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
    AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

```
                  <==  value  columns   ==>
row_name   extra   cat1   cat2   cat3   cat4
---------+-------+------+------+------+------
  row1     extra1  val1   val2          val4
  row2     extra2  val5   val6   val7   val8
```

The `FROM` clause must define the proper number of output columns of the proper data types. If there are *`N`* columns in the *`source_sql`* query's result, the first *`N`*-2 of them must match up with the first *`N`*-2 output columns. The remaining output columns must have the type of the last column of the *`source_sql`* query's result, and there must be exactly as many of them as there are rows in the *`category_sql`* query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching

`category` values. If a row's `category` does not match any output of the *`category_sql`* query, its `value` is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *`source_sql`* query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the *`category_sql`* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,

(2 rows)
```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

F.75.1.5. connectby

```
connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])
```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.55 explains the parameters.

Table F.55. `connectby` Parameters

Parameter	Description
relname	Name of the source relation
keyid_fld	Name of the key field
parent_keyid_fld	Name of the parent-key field
orderby_fld	Name of the field to order siblings by (optional)
start_with	Key value of the row to start at
max_depth	Maximum depth to descend to, or zero for unlimited depth
branch_delim	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
    AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be

of type `integer`. If a *`branch_delim`* parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an *`orderby_fld`* parameter was given, the last output column is a serial number, and must be of type `integer`.

The "branch" output column shows the path of keys taken to reach the current row. The keys are separated by the specified *`branch_delim`* string. If no branch display is wanted, omit both the *`branch_delim`* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the *`orderby_fld`* parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if *`orderby_fld`* is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the *`branch_delim`* string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if *`branch_delim`* is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);

-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
 AS t(keyid text, parent_keyid text, level int, branch text);
 keyid | parent_keyid | level |       branch
-------+--------------+-------+--------------------
 row2  |              |     0 | row2
 row4  | row2         |     1 | row2~row4
 row6  | row4         |     2 | row2~row4~row6
 row8  | row6         |     3 | row2~row4~row6~row8
 row5  | row2         |     1 | row2~row5
 row9  | row5         |     2 | row2~row5~row9
(6 rows)

-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
 AS t(keyid text, parent_keyid text, level int);
 keyid | parent_keyid | level

 row4  | row2         |     1 |   4
 row6  | row4         |     2 |   5
 row8  | row6         |     3 |   6
(6 rows)
```

F.75.2. Author

Joe Conway

F.76. tcn — a trigger function to notify listeners of changes to table content

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER` trigger `FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test-#   (
test(#     a int not null,
test(#     b date not null,
test(#     c text,
test(#     primary key (a, b)
test(#   );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test-#   after insert or update or delete on tcndata
test-#   for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test-#                            (1, date '2012-12-23', 'another'),
test-#                            (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
 received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
 received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
 received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
 received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
 received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
 received from server process with PID 22770.
```

F.77. test_decoding — SQL-based test/example module for WAL logical decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 location  | xid |                       data
-----------+-----+------------------------------------------------
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```
postgres[33712]=#* SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL,
 'stream-changes', '1');
    lsn    | xid |                       data
-----------+-----+------------------------------------------------
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16B21F8 | 503 | streaming change for TXN 503
 0/16B2300 | 503 | streaming change for TXN 503
 0/16B2408 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16BECA8 | 503 | streaming change for TXN 503
 0/16BEDB0 | 503 | streaming change for TXN 503
 0/16BEEB8 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
(10 rows)
```

F.78. tsm_system_rows — the SYSTEM_ROWS sampling method for TABLESAMPLE

The tsm_system_rows module provides the table sampling method SYSTEM_ROWS, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in SYSTEM sampling method, SYSTEM_ROWS performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

SYSTEM_ROWS does not support the REPEATABLE clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.78.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_ROWS. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a SELECT command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table my_table (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.79. tsm_system_time — the SYSTEM_TIME sampling method for TABLESAMPLE

The tsm_system_time module provides the table sampling method SYSTEM_TIME, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in SYSTEM sampling method, SYSTEM_TIME performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

SYSTEM_TIME does not support the REPEATABLE clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.79.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_TIME. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a SELECT command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of my_table as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

F.80. unaccent — a text search dictionary which removes diacritics

unaccent is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of unaccent cannot be used as a normalizing dictionary for the thesaurus dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.80.1. Configuration

An unaccent dictionary accepts the following options:

- RULES is the base name of the file containing the list of translation rules. This file must be stored in $SHAREDIR/tsearch_data/ (where $SHAREDIR means the Postgres Pro installation's shared-data directory). Its name must end in .rules (which is not to be included in the RULES parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

  ```
  À       A
  Á       A
  Â       A
  Ã       A
  Ä       A
  Å       A
  Æ       AE
  ```

  The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.
- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so unaccent dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in unaccent.rules, which is installed in $SHAREDIR/tsearch_data/ when the unaccent module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, Æ to AE).

F.80.2. Usage

Installing the unaccent extension creates a text search template unaccent and a dictionary unaccent based on it. The unaccent dictionary has the default parameter setting RULES='unaccent', which makes it immediately usable with the standard unaccent.rules file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----------
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
    to_tsvector
-------------------
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
 ?column?
----------
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
      ts_headline
------------------------
 <b>Hôtel</b> de la Mer
(1 row)
```

F.80.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([`*`dictionary`* `regdictionary, ] `*`string`* `text) returns text`

If the *`dictionary`* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.81. uuid-ossp — a UUID generator

The uuid-ossp module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core Postgres Pro. See Section 9.14 for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.81.1. uuid-ossp Functions

Table F.56 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and *RFC 4122* specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.56. Functions for UUID Generation

Function Description
uuid_generate_v1 () → uuid Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
uuid_generate_v1mc () → uuid Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.
uuid_generate_v3 (*namespace* uuid, *name* text) → uuid Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the uuid_ns_*() functions shown in Table F.57. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: `SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');` The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.
uuid_generate_v4 () → uuid Generates a version 4 UUID, which is derived entirely from random numbers.
uuid_generate_v5 (*namespace* uuid, *name* text) → uuid Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

Table F.57. Functions Returning UUID Constants

Function Description
uuid_nil () → uuid Returns a “nil” UUID constant, which does not occur as a real UUID.
uuid_ns_dns () → uuid Returns a constant designating the DNS namespace for UUIDs.

Function Description
uuid_ns_url () → uuid Returns a constant designating the URL namespace for UUIDs.
uuid_ns_oid () → uuid Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.)
uuid_ns_x500 () → uuid Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.

F.81.2. Building uuid-ossp

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at *http://www.ossp.org/pkg/lib/uuid/*, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. uuid-ossp can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core libc library. On Linux, macOS, and some other platforms, suitable functions are provided in the libuuid library, which originally came from the e2fsprogs project (though on modern Linux it is considered part of util-linux-ng). When invoking configure, specify --with-uuid=bsd to use the BSD functions, or --with-uuid=e2fs to use e2fsprogs' libuuid, or --with-uuid=ossp to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so configure does not automatically choose one.

F.81.3. Author

Peter Eisentraut <peter_e@gmx.net>

F.82. vops — support for vector operations

> **Important**
>
> The vops extension is considered deprecated. It is not recommended to use it.

The vops module is an experimental Postgres Pro Enterprise extension that provides support for vector operations, which allows to speed up OLAP queries with filtering and aggregation more than 10 times. Performance improvements are achieved by implementing a vertical data model that allows storing data in *tiles*, or groups of column values. Such a storage format is also called *Parquet* in some analytical databases. Reducing the overhead of unpacking tuples, vertical data model allows to speed up query execution without any radical changes in Postgres Pro planner and executor.

vops provides its own set of vector functions that can be used inside predicates and aggregate expressions. To avoid learning new syntax, you can use postgres_fdw as an abstraction layer and run regular SQL queries on vectorized data. For query types other than filtering and aggregation, vops can also use postgres_fdw to present vectorized data as a regular table with scalar column types and process this data as regular tuples. For ease of use, vops also provides an automated way of generating and accessing vectorized data, as explained in Section F.82.5.5.

F.82.1. Limitations

- Tile-based tables only allow INSERT and APPEND operations. Once imported, vectorized data cannot be updated.
- Vector operations are only available for filtering and aggregation. Other query types are supported via postgres_fdw.
- Aggregate expressions must be of the same type.
- JOIN operations are not supported for vector types. You have to use postgres_fdw to transform vectorized data back to regular tuples to run such queries.
- Since postgres_fdw does not support parallel query execution, you can only run parallel queries when using vector operators directly.

F.82.2. Installation and Setup

The vops extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable vops:

1. Add vops to the shared_preload_libraries parameter in the postgresql.conf file:

   ```
   shared_preload_libraries = 'vops'
   ```

   > **Note**
   >
   > If the extension library is not added to the shared_preload_libraries list, it will be loaded on demand after the first function invocation of this extension. In this case, the first time you execute a vectorized query, it will not be processed correctly and can return a wrong result.

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.
3. Create vops extension:

   ```
   CREATE EXTENSION vops;
   ```

Once vops is enabled, you can create vectorized tables and query data using vector operations in your database.

If you would like to use regular SQL syntax for vector types, you must also enable postgres_fdw.

F.82.3. Motivation

For OLTP workloads, Postgres Pro looks very competitive as compared to other mainstream databases. However, for OLAP queries, which require processing larger volumes of data, analytics-oriented database management systems can provide a much better speed. There are several main factors that limit Postgres Pro performance:

- Tuple unpacking overhead. To access column values, Postgres Pro needs to unpack the tuple. As tables can have columns of variable-length data types, to extract the N-th column, the preceding N-1 columns need to be unpacked. Thus, deforming a tuple is quite an expensive operation, especially for tables with a large number of attributes. Besides, values can be compressed or stored in another page (TOAST). In queries like Query 6 of the *TPC-H benchmark*, deforming tuples takes about 40% of the total query execution time.
- Interpretation overhead. Postgres Pro planner and optimizer build a tree representing the query execution plan. Query executor recursively calls functions that evaluate the nodes of this tree. Some nodes may also contain switches used to select the requested action. Thus, query plan is interpreted by Postgres Pro query executor rather than directly executed. The interpreter is usually about 10 times slower than the native code. If you eliminate interpretation overhead, you can increase query speed several times, especially for queries with complex predicates that have high evaluation costs.
- Abstraction penalty. Support for abstract (user-defined) types and operations is one of the key features of Postgres Pro. However, the price of such flexibility is that each operation requires a separate function call. Instead of adding two integers directly, Postgres Pro executor invokes a function that performs addition. In this case, function call overhead is much higher than the cost the operation itself. Function call overhead is also increased because Postgres Pro requires passing parameter values through memory.
- Pull model overhead. In Postgres Pro, operators pull the operand values. This approach simplifies the implementation of operators and the executor, but has a negative impact on performance. In this model, leaf nodes that fetch a tuple from the heap or index pages have to do a lot of extra work while saving and restoring their context.
- MVCC overhead. Postgres Pro provides multi-version concurrency control, which allows multiple transactions to work with the same record in parallel without blocking each other. It is good for frequently updated data (OLTP), but for read-only or append-only data in OLAP scenarios it only adds both space overhead (about 20 extra bytes per tuple) and CPU overhead (checking visibility of each tuple).

Vector operations can address most of these issues without radical changes in the Postgres Pro executor, as explained in Section F.82.4.

F.82.4. Architecture

The `vops` extension implements a *vertical data model* for Postgres Pro. In this model, vertical columns are used as a data storing unit, with the values of the corresponding table attribute forming a vector.

The vertical data model used by `vops` has the following advantages:

- Reduces the size of fetched data: only the columns used in the query need to be fetched.
- Achieves higher compression rates: storing all values of the same attribute together makes it possible to compress them much better and faster. For example, you can use delta encoding.
- Minimizes interpretation overhead: a set of values can be processed by a single operation instead of running separate operations for each value.
- Uses CPU vector instructions (SIMD) to process data.

A traditional Postgres Pro query executor deals with a single row of data at each moment of time. For example, to evaluate an expression `(x+y)`, it first fetches the value of `x`, then fetches the value of `y`, performs the addition, and returns the result value to the upper node. In contrast, a vectorized executor can process multiple values within a single operation. In this case, `x` and `y` represent vectors of values

instead of single scalars. The returned result is also a vector. In vector execution model, interpretation and function call overhead is divided by the vector size. The price of performing a function call is the same, but as the function processes N values instead of a single one, this overhead becomes less critical. The larger the vector, the smaller the per-row overhead.

However, performing an operation on the whole column may also turn out to be ineffective. Working with large vectors prevents efficient utilization of CPU cache levels. If the table is very large, the vector may not fit in memory at all. To avoid these issues, `vops` splits the columns into relatively small chunks, or *tiles*. The size of a tile is currently set to 64 elements. It allows to keep all operands of vector operations in cache, even for complex expressions.

The `vops` extension implements special vector types to be used instead of scalar types for table columns. The available types are listed in Section F.82.6.1. To use `vops`, you have to create vectorized projections of original tables, with at least some attributes using these tile types, as explained in Section F.82.5.1.

The original table can be treated as a write-optimized storage: if it has no indexes, Postgres Pro can provide a very fast insertion speed, comparable to raw disk write speed. Vectorized projection can be treated as a read-optimized storage, which is most efficient for running OLAP queries.

Once all the data is in the tile-based format, you can run vectorized queries on this data. `vops` provides a set of vector operators to work with vector types. Using these operators, you can write queries for filtering and aggregation, similar to SQL queries. For details, see Section F.82.5.2.

For other query types, `vops` allows to work with vectorized data via `postgres_fdw`. You can add vectorized data to your database cluster as a foreign table and use regular SQL for running any types of queries on this data. Using the implicit type casts and post-parse `ANALYZE` hook, the `vops` extension either transforms the query to use vector operators for filtering and aggregation, or processes the data using scalar operators for other query types. For details, see Section F.82.5.3.

F.82.5. Usage

F.82.5.1. Converting Data into Vectorized Format

To start using vector operations, you have to convert your data into a vectorized format, as explained below.

1. **Create an empty vectorized table.**

   To use vector operations, you need to load data into a tile-based vectorized table, which can be treated as a *projection* of the original table. It can map all columns of the original table, or include some of the most frequently used columns only. To create a vectorized table, you can use the regular CREATE TABLE syntax, but at least some of the columns must be of vector types.

   For example, suppose you have the following table from the TPC-H benchmark:

```
CREATE TABLE lineitem(
   l_orderkey integer,
   l_partkey integer,
   l_suppkey integer,
   l_linenumber integer,
   l_quantity double precision,
   l_extendedprice double precision,
   l_discount double precision,
   l_tax double precision,
   l_returnflag "char",
   l_linestatus "char",
   l_shipdate date,
   l_commitdate date,
   l_receiptdate date,
```

```
    l_shipinstruct char(25),
    l_shipmode char(10),
    l_comment char(44));
```

To create a vectorized projection that includes only a subset of the original columns, you can run:

```
CREATE TABLE vops_lineitem(
    l_shipdate vops_date not null,
    l_quantity vops_float8 not null,
    l_extendedprice vops_float8 not null,
    l_discount vops_float8 not null,
    l_tax vops_float8 not null,
    l_returnflag vops_char not null,
    l_linestatus vops_char not null
);
```

Alternatively, you can keep the scalar type for some of the columns. In this case, you can sort the data by these columns when loading the data. For example, let's create another vectorized projection where `l_returnflag` and `l_linestatus` fields remain scalar:

```
CREATE TABLE vops_lineitem_projection(
    l_shipdate vops_date not null,
    l_quantity vops_float8 not null,
    l_extendedprice vops_float8 not null,
    l_discount vops_float8 not null,
    l_tax vops_float8 not null,
    l_returnflag "char" not null,
    l_linestatus "char" not null
);
```

In this table, `l_returnflag` and `l_linestatus` fields are scalar, while all the other fields are of the vector types that can be used in vector operations.

2. **Load the data into the vectorized table.**

   - If the data to load is already stored in your database, use the populate() function to preprocess the data and unite attribute values of several rows inside a single tile. This function loads the data from the original table into its vectorized projection, using vector types instead of scalar types, as specified in the created empty table.

     For example:

     ```
     SELECT populate(destination := 'vops_lineitem'::regclass, source :=
      'lineitem'::regclass);
     ```

     Once the table is populated, you can start running queries performing sequential scan.

     Optionally, you can sort the data by one or more scalar columns when loading the data:

     ```
     SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=
      'lineitem'::regclass, sort := 'l_returnflag,l_linestatus');
     ```

     If you sort the original table by the scalar columns that have a lot of duplicates, `vops` can effectively collapse them and store the corresponding attribute values in tiles, which can reduce the occupied space, speed up queries, and facilitate index creation on these scalar columns.

   - If your data is not yet loaded into the database and you would like to avoid having two copies of the same dataset, you can import the data into a vectorized table directly from a CSV file using the import() function, bypassing creation of a regular table. For example:

     ```
     SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/
     lineitem.csv', separator := '|');
     ```

For detailed description and syntax of the `populate()` and `import()` functions, see Section F.82.6.4.

Once your data is in the tile-based format, you can run queries on this data using vector operators, as described in Section F.82.5.2. If you create a foreign vectorized table, you can also run regular SQL queries. See Section F.82.5.3 for details.

F.82.5.2. Running Queries on Vectorized Data

`vops` implements its own vector functions and operators for working with vectorized data. See Section F.82.6 for the full list of vector functions and operators and their usage specifics.

F.82.5.2.1. Aggregating Vectorized Data

OLAP queries often aggregate large volumes of data. To enable aggregate operations for vector types, `vops` implements the following aggregate functions for vectorized data: `count`, `min`, `max`, `avg`, `var_pop`, `var_sampl`, `variance`, `stddev_pop`, `stddev_samp`, `stddev`. Besides, `vops` provides the `wavg` aggregate function that calculates volume-weighted average price (VWAP).

The `vops` extension supports the following types of aggregates:

- grand aggregates calculated for the whole table
- aggregates for subsets of table rows defined by the `GROUP BY` clause

F.82.5.2.1.1. Calculating Grand Aggregates

To calculate grand aggregates, you can use the provided vector aggregate functions exactly like in regular SQL queries.

Examples:

To calculate volume-weighted average price, run the following query:

```
SELECT wavg(l_extendedprice,l_quantity) FROM vops_lineitem;
```

To calculate the company revenue for the year 1996 based on discounted prices of the shipped goods, run:

```
SELECT sum(l_extendedprice*l_discount) AS revenue
  FROM vops_lineitem
  WHERE filter(betwixt(l_shipdate, '1996-01-01', '1997-01-01')
        & betwixt(l_discount, 0.08, 0.1)
        & (l_quantity < 24));
```

F.82.5.2.1.2. Calculating Grouped Aggregates

To support grouped aggregates, `vops` provides `map()` and `reduce()` functions:

- The `map()` function collects aggregate states for all groups in a hash table. Its syntax is as follows:

  ```
  map(group_by_expression,
        aggregate_list, expr {,
        expr })
  ```
- The `reduce()` function iterates through the hash table constructed by `map` and returns the set. The `reduce` function is needed because the result of aggregation in Postgres Pro cannot be a set.

Consider the following example:

```
SELECT reduce(map(l_returnflag||l_linestatus, 'sum,sum,sum,sum,avg,avg,avg',
    l_quantity,
    l_extendedprice,
    l_extendedprice*(1-l_discount),
    l_extendedprice*(1-l_discount)*(1+l_tax),
    l_quantity,
    l_extendedprice,
```

```
    l_discount))
FROM vops_lineitem
WHERE filter(l_shipdate <= '1998-12-01'::date);
```

The concatenation operator `||` performs grouping by two columns. The `vops` extension supports grouping only by an integer type. The `map` function accepts aggregation arguments as a variadic array, so all elements of this array should have the same type. For example, you cannot calculate aggregates for `vops_float4` and `vops_int8` columns in a single operation.

An aggregate string in `map` function should contain the list of aggregate functions to call, in a comma-separated format. Standard lowercase names should be used: `count`, `sum`, `agg`, `min`, `max`. Count is executed for the particular column: `count(x)`. There is no need to explicitly specify `count(*)` because the number of records in each group is returned by `reduce` function in any case.

`reduce` function returns set of the `vops_aggregate` type. It contains three components: the value of the `GROUP BY` expression, the number of records in the group, and an array of floats with aggregate values. The values of all aggregates, including `count` and `min/max`, are returned as floats.

Alternatively, you can partition the vectorized table by the `GROUP BY` fields to calculate grouped aggregates. In this case, grouping keys are stored as regular scalar values, while other fields are stored inside tiles. Now Postgres Pro executor will execute vops aggregates for each group:

```
SELECT
    l_returnflag,
    l_linestatus,
    sum(l_quantity) as sum_qty,
    sum(l_extendedprice) AS sum_base_price,
    sum(l_extendedprice*(1-l_discount)) AS sum_disc_price,
    sum(l_extendedprice*(1-l_discount)*(1+l_tax)) AS sum_charge,
    avg(l_quantity) AS avg_qty,
    avg(l_extendedprice) AS avg_price,
    avg(l_discount) AS avg_disc,
    count(*) AS count_order
FROM
    vops_lineitem_projection
WHERE
    filter(l_shipdate <= '1998-12-01'::date)
GROUP BY
    l_returnflag,
    l_linestatus
ORDER BY
    l_returnflag,
    l_linestatus;
```

In this example, `l_returnflag` and `l_linestatus` fields of the `vops_lineitem_projection` table have the `char` type, while all the other used fields are of vector types. The query above is executed even faster than query with the `map()` and `reduce()` functions. The main problem with this approach is that you have to create a separate projection for each combination of the `GROUP BY` keys to be used in queries.

F.82.5.2.2. Using Vector Window Functions

The `vops` extension provides limited support for Postgres Pro window functions. It provides `mcount`, `msum`, `mmin`, `mmax`, `mavg`, and `lag` functions that correspond to the standard Postgres Pro window functions `count`, `sum`, `min`, `max`, `avg`, and `lag` functions, respectively.

Note the following important restrictions:

1. Filtering, grouping, and sorting can be done only by scalar attributes.
2. Vector window functions only support window frames specified with `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

Examples:

```
SELECT vops_unnest(t.*)
  FROM (SELECT mcount(*) over w,mcount(x) over w,msum(x) over w,mavg(x) over w,mmin(x)
 over w,mmax(x) over w,x - lag(x) over w
  FROM v window w
  AS (rows between unbounded preceding and current row)) t;
```

F.82.5.2.3. Converting Results to Horizontal Format

A query from the `vops` projection returns a set of tiles. The output function of a tile type can print the tile contents. However, if you want to convert the result to the horizontal format where each tuple represents a single record, use the vops-unnest function. For example:

```
SELECT vops_unnest(l.*)
  FROM vops_lineitem l
  WHERE filter(l_shipdate >= '1998-12-01'::date);
```

F.82.5.3. Using Standard SQL for Vector Operations

Vector operators can efficiently execute only filtering and aggregation queries. For other query types, you have to run regular SQL queries. The `vops` extension offers the following options:

- Use the original table, if any.
- Enable a foreign data wrapper (FDW) using `postgres_fdw` to present a vectorized table to Postgres Pro as a regular table with scalar column types.

If you use `postgres_fdw` with the `vops` extension, vectorized data is not really foreign: it is stored inside the database in an alternative vectorized format. FDW allows to hide specifics of the vectorized format and provides the following opportunities for working with vectorized data:

1. Extract the data from a vectorized table and present it in the horizontal format, so that it can be processed by upper nodes in the query execution plan.
2. Push filtering and aggregation queries down to vector operations.
3. Get statistic for the underlying table by running `ANALYZE` for the foreign table. The collected statistic can be used by the query optimizer, so query execution plan should be almost the same as for regular tables.

Thus, by placing a vectorized projection under FDW, you can use standard SQL without any `vops`-specific functions to perform sequential scan and aggregation queries as if they are explicitly written for the `vops` table, and execute any other queries on this data at the same time, including `JOIN` operations, common table expressions (CTE), etc. The queries that can be efficiently executed by vector operations will be pushed by Postgres Pro query optimizer to `vops` FDW and will be executed using vector operators. For other queries, the data is fetched from vectorized tables as standard tuples. If it is determined that vector operations are required, `vops` uses a post-parse `ANALYZE` hook that replaces scalar boolean operations with vector boolean operations:

Original Expression	Transformed Expression
`NOT filter(o1)`	`filter(vops_bool_not(o1))`
`filter(o1) AND filter(o2)`	`filter(vops_bool_and(o1, o2))`
`filter(o1) OR filter(o2)`	`filter(vops_bool_or(o1, o2))`

There is only one difference between standard SQL and its vectorized extension. You still have to perform explicit type cast for string literals. For example, `l_shipdate <= '1998-12-01'` will not work for the `l_shipdate` column with vector type. Postgres Pro Enterprise has two overloaded versions of the **<=** operator to choose the appropriate scalar or vector type:

- `vops_date` **<=** `vops_date`

- vops_date **<=** date

The example below shows creation of a vectorized table via postgres_fdw and some queries on it:

```
CREATE FOREIGN TABLE lineitem_fdw (
   l_suppkey int4 not null,
   l_orderkey int4 not null,
   l_partkey int4 not null,
   l_shipdate date not null,
   l_quantity float8 not null,
   l_extendedprice float8 not null,
   l_discount float8 not null,
   l_tax      float8 not null,
   l_returnflag "char" not null,
   l_linestatus "char" not null
) SERVER vops_server OPTIONS (table_name 'vops_lineitem');

EXPLAIN SELECT
   sum(l_extendedprice*l_discount) AS revenue
FROM
   lineitem_fdw
WHERE
   l_shipdate BETWEEN '1996-01-01' AND '1997-01-01'
   AND l_discount BETWEEN 0.08 AND 0.1
   AND l_quantity < 24;
                        QUERY PLAN
-----------------------------------------------------------
 Foreign Scan  (cost=1903.26..1664020.23 rows=1 width=4)
(1 row)

-- Filter was pushed down to FDW

EXPLAIN SELECT

                                        ->  Hash Join  (cost=40.97..2790.80 rows=7702
width=44)
                                              Hash Cond: (supplier_fdw.s_nationkey =
nation.n_nationkey)
                                              ->  Foreign Scan on supplier_fdw
(cost=0.00..2174.64 rows=100032 width=8)
                                              ->  Hash  (cost=40.79..40.79 rows=15
width=36)
                                                    ->  Hash Join  (cost=20.05..40.79
rows=15 width=36)
                                                          Hash Cond: (nation.n_regionkey
= region.r_regionkey)
                                                          ->  Seq Scan on nation
(cost=0.00..17.70 rows=770 width=40)
                                                          ->  Hash  (cost=20.00..20.00
rows=4 width=4)
                                                                ->  Seq Scan on region
(cost=0.00..20.00 rows=4 width=4)
                                                                      Filter:
((r_name)::text = 'ASIA'::text)
                            ->  Hash  (cost=294718.76..294718.76 rows=2284376 width=8)
                                  ->  Foreign Scan on orders_fdw  (cost=0.00..294718.76
rows=2284376 width=8)
                      ->  Hash  (cost=32605.64..32605.64 rows=1500032 width=8)
                            ->  Foreign Scan on customer_fdw  (cost=0.00..32605.64
rows=1500032 width=8)

-- filter on orders range is pushed to FDW
```

F.82.5.4. Building Indexes for Vectorized Tables

Analytic queries are usually performed on the data for which no indexes are defined. Vector operations on tiles are most effective in this case. However, you can still use indexes with vectorized data.

Since each tile represents multiple values, an index can be used only for some preliminary, non-precise filtering of data. The `vops` extension provides the following pairs of functions to obtain boundary values stored in the tile:

- `first()` and `last()` functions should be used for sorted dataset. In this case, the first and the last values in the tile are the smallest and the largest values in the tile, respectively.
- `high()` and `low()` functions should be used for unsorted data. These functions are more expensive because they need to inspect all tile values.

Using the returned values, you can construct functional indexes for vectorized data. The BRIN index seems to be the best choice:

```
CREATE INDEX low_boundary ON trades
USING brin(first(day)); -- trades table is ordered by day
CREATE INDEX high_boundary ON trades
USING brin(last(day)); -- trades table is ordered by day
```

Now you can use the created indexes in queries. However, you have to recheck the precise condition because such an index only gives an approximate result:

```
SELECT sum(price) FROM trades
WHERE first(day) >= '2015-01-01' AND last(day) <= '2016-01-01'
AND filter(betwixt(day, '2015-01-01', '2016-01-01'));
```

F.82.5.5. Automating Projection Usage

`vops` can automate most of the operations required to create and maintain vectorized data projections. In this case, you do not have to use postgres_fdw: `vops` can redirect regular SQL queries to projection tables automatically. However, these queries must satisfy the following criteria to get redirected:

- The query does not contain joins.
- The query performs aggregation of vector columns.
- All other expressions in the target list, as well as `ORDER BY` and `GROUP BY` clauses refer only to scalar columns.

To enable automatic query redirection to a vectorized projection of your data, do the following:

1. **Create a vectorized projection of the table using the create_projection() function.**

   For example, to create a projection for the `lineitem` table shown above, similar to the `vops_lineitem`, run:

   ```
   SELECT create_projection('auto_vops_lineitem','lineitem',

    array['l_shipdate','l_quantity','l_extendedprice','l_discount','l_tax'],
                            array['l_returnflag','l_linestatus']);
   ```

   In this example, the first two arguments specify the projection table and the original table, respectively, the first array defines all the vector columns to be included into the projection, and the second array specifies the scalar columns that will be used for grouping vectorized data into tiles.

   Additionally, you can provide an optional `order_by` parameter to speed up subsequent projection refresh operations. The `order_by` values should be unique. For example, to sort all table entries by `l_shipdate`, you can create a projection table as follows:

   ```
   SELECT create_projection('auto_vops_lineitem_ordered','lineitem',

    array['l_shipdate','l_quantity','l_extendedprice','l_discount','l_tax'],
                            array['l_returnflag','l_linestatus'],
                            'l_shipdate');
   ```

2. **Set the vops.auto_substitute_projections parameter to `on`.**

   Now all queries that `vops` can redirect to the `auto_vops_lineitem` projection table will be run on the vectorized data.

Projections are not updated automatically, so once the original table gets updated, implicitly redirected queries can start returning inaccurate results. To avoid this, you have to refresh the projections before running queries on the vectorized data. For this purpose, `vops` provides the *pname*`_refresh()` functions, where the *pname* prefix is the name of the projection you need to refresh. For example, to refresh the `auto_vops_lineitem` projection, run:

```
SELECT auto_vops_lineitem_refresh();
```

This function calls the `populate()` method to update all the fields present in the projection. If you have specified the optional `order_by` parameter when creating the projection, only the new data will be im-

ported from the original table, selecting only the rows with the `order_by` column value greater than the maximal value of this column in the projection. Otherwise, the whole table will be re-written. The `populate()` method also takes the grouping columns into account to efficiently group the imported data in tiles.

If you have specified the `order_by` attribute when creating a projection, `vops` also creates the following indexes:

- Two functional BRIN indexes on `first()` and `last()` functions of this attribute. Such indexes allow to efficiently select time slices. For example, if the original query contains predicates like `(l_shipdate between '01-01-2017' and '01-01-2018')`, `vops` adds the `(first(l_shipdate) >= '01-01-2017' and last(l_shipdate) >= '01-01-2018')` conjuncts when redirecting the query, so that Postgres Pro optimizer can quickly locate the affected pages using BRIN indexes.
- A BRIN index for scalar columns used for grouping. Such index allows to efficiently select groups and perform index joins.

F.82.6. Reference

F.82.6.1. Vector Types

The `vops` extension supports all basic Postgres Pro numeric types: 1-, 2-, 4-, 8-byte integers, as well as 4- and 8-byte floats. The `date` and `timestamp` types are using the same implementation as `int4` and `int8`, respectively. The table below illustrates the available vector types, as compared to the corresponding SQL and C types.

SQL Type	C Type	vops Vector Type
bool	bool	vops_bool
"char"	char	vops_char
date	DateADT	vops_date
int2	int16	vops_int2
int4	int32	vops_int4
int8	int64	vops_int8
float4	float4	vops_float4
float8	float8	vops_float8
timestamp	Timestamp	vops_timestamp
char(*N*), varchar(*N*)	text	vops_text(*N*)

> **Note**
>
> For performance reasons, using `vops_text` for single-character strings is not recommended. If you are using strings as identifiers, you can place them in a dictionary and use integer identifiers instead of the original strings.

F.82.6.2. Vector Operators

The `vops` extension provides a set of operators for vector types.

F.82.6.2.1. Mathematical Operators

For mathematical operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

Operator	Description
+	Addition

Operator	Description
-	Binary subtraction or unary negation
*	Multiplication
/	Division
||	Concatenation. This operator is only supported for `char`, `int2`, and `int4` types. It returns an integer type of a doubled size: `(char || char) -> int2` `(int2 || int2) -> int4` `(int4 || int4) -> int8`

F.82.6.2.2. Comparison Operators

For comparison operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

Operator	Description
=	Equals
<>	Not equals
<	Less than
<=	Less than or equals
>	Greater than
>=	Greater than or equals

F.82.6.2.3. Boolean Operators

Boolean operators `AND`, `OR`, and `NOT` cannot be overloaded, so `vops` provides its own implementation of boolean operators for vector types:

Operator	Description
&	Boolean AND
|	Boolean OR
!	Boolean NOT

Vector boolean operators have the following usage specifics:

- The precedence of vector boolean operators is different from `AND`, `OR`, and `NOT`, so you have to enclose the operands into parentheses. For example:

  ```
  (x=1) | (x=2)
  ```
- The result of vector boolean operations is `vops_bool`. Since Postgres Pro requires predicate expressions to have a regular boolean type, you have to convert the result to the `bool` type using the `filter()` function. Taking a vector boolean expression, this function calculates a `filter_mask` value that defines the result of this boolean operation for each vector element. If all mask bits are zero (the predicate is false for all vector elements), then `filter()` returns `false`, and Postgres Pro executor skips this record. Otherwise, `true` is returned, so vector operators will check the `filter_mask` value for the selected vector elements in subsequent operations.
- When using vector boolean operators, you have to use explicit cast of string constants to the required data type.

F.82.6.3. Comparison Functions

Function	Description
`bitwixt(x,low,high)`	Same as the *x* `BETWEEN` *low* `AND` *high* predicate.

Function	Description
is_null(x)	Same as the *expression* IS NULL predicate.
is_not_null(x)	Same as the *expression* IS NOT NULL predicate.
ifnull(x,subst)	Same as the COALESCE function.

F.82.6.4. Conversion Functions

create_projection(*projection_name* text, *source_table* regclass, *vector_columns* text[], *scalar_columns* text[] DEFAULT null, *order_by* text DEFAULT null)

Creates a projection table with specified name and attributes and updates the vops_projections table to include the information about this projection, so that the optimizer can automatically redirect queries from the original table to its projection. It also creates the pname_refresh() function that can update the projection.

Arguments:

- *projection_name* — the name of the projection table.
- *source_table* — the original Postgres Pro table for which to create a vectorized projection.
- *vector_columns* — an array of column names that will be stored as vops tiles.
- *scalar_columns* — an array of column names that will preserve its original scalar type. These columns will be used to group table rows into vops tiles. vops automatically builds a BRIN index over such columns.
- *order_by* — an optional vector column that can be used to sort data in the projection table. Sorting can be useful to incrementally update the projection after the original table updates using the pname_refresh() function. This column should contain unique timestamp values, such as trade dates. vops automatically builds a functional BRIN index for first() and last() functions of this column.

Examples:

```
SELECT
 create_projection('vops_lineitem','lineitem',array['l_shipdate','l_quantity','l_extended
```

*pname*_refresh()

Refreshes the *pname* projection table.

Examples:

Refresh the vops_lineitem projection:

```
SELECT vops_lineitem_refresh();
```

drop_projection(*projection_name* text)

Drops the specified projection and the corresponding refresh function, as well as removes the information about this projection from the vops_projections table.

Examples:

Drop the vops_lineitem projection:

```
SELECT drop_projection(vops_lineitem);
```

populate(*destination* regclass, *source* regclass, *predicate* cstring DEFAULT null, *sort* cstring DEFAULT null)

Copies the data from an existing table to its vectorized projection and returns the number of imported rows (bigint).

Arguments:

- *destination* — target table to copy the data into.

  Type: regclass

- *source* — source table to copy the data from.

  Type: regclass

- *predicate* — restricts the amount of imported data (optional). Using this argument, you can upload only the most recent records.

  Type: cstring

- *sort* — sorts the source data to define the order in which the data needs to be loaded (optional).

  Type: cstring

Examples:

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=
 'lineitem'::regclass);

SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=
 'lineitem_projection'::regclass, sort := 'l_returnflag,l_linestatus');
```

import(*destination* regclass, *csv_path* cstring, *separator* cstring DEFAULT ',' *skip* integer DEFAULT 0)

Loads the data into a vops table directly from a CSV file, bypassing creation of a regular table, and returns the number of imported rows (bigint). Use this function to avoid storing two copies of the same dataset.

Arguments:

- *destination* — target table to copy the data into.

  Type: regclass

- *csv_path* — the path to the CSV file to copy the data from.

  Type: cstring

- *separator* — specifies the field separator used in the CSV file (optional). By default, the comma is assumed to be the field separator.

  Type: cstring

- *skip* — specifies the number of rows in the CSV header that do not need to be imported (optional).

  Default: 0

  Type: cstring

Examples:

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/
lineitem.csv', separator := '|');
```

vops_unnest(anyelement)

Scatters records with vops types into records with scalar types.

F.82.6.5. Configuration Parameters

`vops.auto_substitute_projections` (`boolean`)

Enables automatic query redirection to projection tables. For correct results, you have to ensure that the projection is synchronized with the original table.

Default: `off`

Postgres Professional, Moscow, Russia

F.83. xml2 — XPath querying and XSLT functionality

The xml2 module provides XPath querying and XSLT functionality.

F.83.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that the deficiency can be addressed.

F.83.2. Description of Functions

Table F.58 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

Table F.58. xml2 Functions

Function Description
xml_valid (*document* text) → boolean Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function xml_is_well_formed() . The name xml_valid() is technically incorrect since validity and well-formedness have different meanings in XML.)
xpath_string (*document* text, *query* text) → text Evaluates the XPath query on the supplied document, and casts the result to text.
xpath_number (*document* text, *query* text) → real Evaluates the XPath query on the supplied document, and casts the result to real.
xpath_bool (*document* text, *query* text) → boolean Evaluates the XPath query on the supplied document, and casts the result to boolean.
xpath_nodeset (*document* text, *query* text, *toptag* text, *itemtag* text) → text Evaluates the query on the document and wraps the result in XML tags. If the result is multi-valued, the output will look like: <toptag> <itemtag>Value 1 which could be an XML fragment</itemtag> <itemtag>Value 2....</itemtag> </toptag> If either *toptag* or *itemtag* is an empty string, the relevant tag is omitted.
xpath_nodeset (*document* text, *query* text, *itemtag* text) → text Like xpath_nodeset(document, query, toptag, itemtag) but result omits *toptag*.
xpath_nodeset (*document* text, *query* text) → text Like xpath_nodeset(document, query, toptag, itemtag) but result omits both tags.
xpath_list (*document* text, *query* text, *separator* text) → text Evaluates the query on the document and returns multiple values separated by the specified separator, for example Value 1,Value 2,Value 3 if *separator* is , .
xpath_list (*document* text, *query* text) → text This is a wrapper for the above function that uses , as the separator.

F.83.3. xpath_table

```
xpath_table(text key, text document, text relation, text xpaths, text criteria) returns
 setof record
```

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F.59.

Table F.59. `xpath_table` Parameters

Parameter	Description
key	the name of the "key" field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)
document	the name of the field containing the XML document
relation	the name of the table or view containing the documents
xpaths	one or more XPath expressions, separated by `|`
criteria	the contents of the WHERE clause. This cannot be omitted, so use `true` or `1=1` if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a `FROM` expression, with an `AS` clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The `AS` clause defines the names and types of the columns in the output table. The first is the "key" field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the `AS` clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling `SELECT` statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc.). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                 '/article/title|/article/author/@id',
                 'xpath_string(article_xml,''/article/@date'') > ''2003-03-20'' ')
       AS t(article_id integer, title text, author_id integer),
     tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

F.83.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
              '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num

 id | doc_num | line_num | val1 | val2 | val3
----+---------+----------+------+------+------
  1 | C1      | L1       |    1 |    2 |    3
  1 |         | L2       |   11 |   22 |   33
```

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
    AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
    AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

```
 id | line_num | val1 | val2 | val3 | doc_num
----+----------+------+------+------+---------
  1 | L1       |    1 |    2 |    3 | C1
  1 | L2       |   11 |   22 |   33 | C1
(2 rows)
```

F.83.4. XSLT Functions

The following functions are available if libxslt is installed:

F.83.4.1. xslt_process

```
xslt_process(text document, text stylesheet, text paramlist) returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

Appendix G. Postgres Pro Modules and Extensions Shipped as Individual Packages

This appendix contains Postgres Pro modules and extensions that are made available in Postgres Pro Enterprise as individual packages. These packages are listed in Section 17.1.4.1, and the documentation for each module explains which package to choose to install it. Appendix F and Appendix H cover more modules and extensions included in the Postgres Pro Enterprise distribution. Note also the pg_portal_modify extension, which is shipped as an individual package, and the `pgpro-orautl` package, which provides packages for utl_http, utl_mail, and utl_smtp (see Section 17.1.4.1 for details).

G.1. pgpro_anonymizer — mask or replace sensitive data

pgpro_anonymizer is an extension to mask or replace personally identifiable information (PII) or commercially sensitive data from a Postgres Pro database.

The project has a *declarative approach* of anonymization. This means you can declare the masking rules using the Data Definition Language (DDL) and specify your anonymization strategy inside the table definition itself.

Once the masking rules are defined, you can access the anonymized data in one of the following ways:

- Anonymous dumps: simply export the masked data into an SQL file.
- Static masking: remove the PII according to the rules.
- Dynamic masking: hide PII only for the masked users.

In addition, various functions are available to implement the following masking techniques: randomization, faking, partial scrambling, shuffling, noise. You can also create a custom function.

Beyond masking, you can also use another approach called generalization, which is useful for statistics and data analytics.

G.1.1. Terms and Definitions

The following main strategies are used:

- *Dynamic masking* offers an altered view of the real data without modifying it. Some users may only read the masked data, others may access the authentic version.
- *Static masking* is the definitive action of substituting the sensitive information with uncorrelated data. Once processed, the authentic data cannot be retrieved.

The data can be altered with several techniques:

- *Deletion* simply removes data.
- *Static substitution* consistently replaces the data with a generic value. For instance: replacing all values of a `text` column with the value “CONFIDENTIAL”.
- *Variance* “shifts” dates and numeric values. For example, by applying a +/- 10% variance to a salary column, the dataset will remain meaningful.
- *Generalization* reduces the accuracy of the data by replacing it with a range of values. Instead of saying “Bob is 28 years old”, you can say “Bob is between 20 and 30 years old”. This is useful for analytics because the data remains true.
- *Shuffling* mixes values within the same columns. This method is open to being reversed if the shuffling algorithm can be deciphered.

- *Randomization* replaces sensitive data with *random-but-plausible* values. The goal is to avoid any identification from the data record while remaining suitable for testing, data analysis and data processing.
- *Partial scrambling* is similar to static substitution but leaves out some part of the data. For instance: a credit card number can be replaced by “40XX XXXX XXXX XX96”.
- *Custom rules* are designed to alter data following specific needs (e.g., simultaneously randomize a zipcode and a city name while keeping them coherent).
- *Pseudonymization* is a way to *protect* personal information by hiding it using additional information. *Encryption* and *hashing* are two examples of pseudonymization techniques. However, pseudonymizated data is still linked to the original data.

G.1.2. Anonymization Example

Suppose you want to mask last names and phone numbers:

```
SELECT * FROM people;
 id | firstname | lastname |   phone
----+-----------+----------+------------
 T1 | Sarah     | Connor   | 0609110911
```

1. Activate the dynamic masking engine:

   ```
   SELECT anon.start_dynamic_masking();
   ```

2. Declare a masked user:

   ```
   CREATE ROLE skynet LOGIN;
   SECURITY LABEL FOR anon ON ROLE skynet IS 'MASKED';
   ```

3. Declare the masking rules:

   ```
   SECURITY LABEL FOR anon ON COLUMN people.lastname
   IS 'MASKED WITH FUNCTION anon.fake_last_name()';

   SECURITY LABEL FOR anon ON COLUMN people.phone
   IS 'MASKED WITH FUNCTION anon.partial(phone,2,$$******$$,2)';
   ```

4. Connect with the masked user:

   ```
   \connect - skynet
   SELECT * FROM people;
    id | firstname | lastname  |   phone
   ----+-----------+-----------+------------
    T1 | Sarah     | Stranahan | 06******11
   ```

G.1.3. Installation and Setup

The `pgpro_anonymizer` extension is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-anonymizer-ent-16` (for the detailed installation instructions, see Chapter 17). To enable `pgpro_anonymizer`, complete the following steps:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'anon'
   ```

2. Reload the database server for the changes to take effect.

> **Note**
>
> To verify that the library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Create the extension using the following query:

   ```
   CREATE EXTENSION anon CASCADE;
   ```

4. Initialize the extension:

   ```
   SELECT anon.init();
   ```

   The `init()` function imports a default dataset of random data (IBAN, names, cities, etc.). This dataset is in English and is very small (1000 values for each category).

G.1.4. Configuration

The extension has several options that can be defined for the entire instance (in `postgresql.conf` or with `ALTER SYSTEM`).

It is also possible and often a good idea to define them at the database level like this:

```
ALTER DATABASE customers SET anon.algorithm = sha512;
```

Only a superuser can change the parameters below:

`anon.algorithm`

The hashing method used by pseudonymizing functions. Checkout the pgcrypto documentation for the list of available options.

See `anon.salt` to learn why this parameter is a very sensitive information.

Type: `text`

Default: `sha256`

Visible: only to superusers

`anon.maskschema`

The schema (i.e. namespace) where the dynamic masking views will be stored.

Type: `text`

Default: `mask`

Visible: to all users

`anon.restrict_to_trusted_schemas`

When this parameter is enabled (by default), masking rules must be defined using functions located in a limited list of namespaces. By default, `pg_catalog` and `anon` are trusted.

This improves security by preventing users from declaring their custom masking filters.

This also means that the schema must be explicit inside the masking rules. For instance, the rules below would fail because the schema of the `lower` function is not declared.

```
SECURITY LABEL FOR anon ON COLUMN people.name
IS 'MASKED WITH FUNCTION lower(people.name)';
```

The correct way to declare it would be:

```
SECURITY LABEL FOR anon ON COLUMN people.name
IS 'MASKED WITH FUNCTION pg_catalog.lower(people.name)';
```

Type: `boolean`

Default: `on`

Visible: to all users

`anon.salt`

The salt used by pseudonymizing functions. It is very important to define a custom salt for each database like this:

```
ALTER DATABASE foo SET anon.salt = 'This_Is_A_Very_Secret_Salt';
```

If masked users can read the salt, they can run a brute force attack to retrieve the original data based on the following elements:

- The pseudonymized data
- The hashing algorithm (see `anon.algorithm`)
- The salt

The salt and the name of the hashing algorithm should be protected with the same level of security that the data itself. This is why the salt should be stored directly within the database with `ALTER DATABASE`.

Type: `text`

Default: (empty)

Visible: only to superusers

`anon.sourceshema`

The schema (i.e. namespace) where the tables are masked by the dynamic masking engine.

Change this value before starting dynamic masking.

```
ALTER DATABASE foo SET anon.sourceschema TO 'my_app';
```

Then reconnect so that the change takes effect and start the engine.

```
SELECT anon.start_dynamic_masking();
```

Type: `text`

Default: `public`

Visible: to all users

G.1.5. Declare Masking Rules

The main idea of this extension is to offer *anonymization by design*.

The data masking rules should be written by people who develop the application because they have the best knowledge of how the data model works. Therefore, masking rules must be implemented directly inside the database schema.

This allows to mask the data directly inside the Postgres Pro instance without using an external tool, and thus limiting the exposure and the risks of data leak.

The data masking rules are declared simply by using security labels:

```
CREATE TABLE player (id SERIAL, name TEXT, points INT);

INSERT INTO player VALUES
  ( 1, 'Kareem Abdul-Jabbar', 38387),
```

```
    ( 5, 'Michael Jordan', 32292 );

SECURITY LABEL FOR anon ON COLUMN player.name
  IS 'MASKED WITH FUNCTION anon.fake_last_name()';

SECURITY LABEL FOR anon ON COLUMN player.id
  IS 'MASKED WITH VALUE NULL';
```

> **Important**
>
> The masking rules are not inherited. If you have split a table into multiple partitions, you need to declare the masking rules for each partition.

G.1.5.1. Escaping String Literals

As you may have noticed, the masking rule definitions are placed between single quotes. Therefore, if you need to use a string inside a masking rule, use dollar quoting:

```
SECURITY LABEL FOR anon ON COLUMN player.name
  IS 'MASKED WITH VALUE $$CONFIDENTIAL$$';
```

G.1.5.2. Using Expressions

You can use more advanced expressions with the `MASKED WITH VALUE` syntax:

```
SECURITY LABEL FOR anon ON COLUMN player.name
  IS 'MASKED WITH VALUE CASE WHEN name IS NULL
                             THEN $$John$$
                             ELSE anon.random_string(LENGTH(name))
                             END';
```

G.1.5.3. Removing a Masking Rule

You can simply erase a masking rule like this:

```
SECURITY LABEL FOR anon ON COLUMN player.name IS NULL;
```

To remove all rules at once, you can use:

```
SELECT anon.remove_masks_for_all_columns();
```

G.1.6. Masking Functions

The extension provides functions to implement the following main anonymization strategies:

- Deletion
- Adding noise
- Randomization
- Faking
- Advanced faking
- Pseudonymization
- Generic hashing
- Partial scrambling
- Generalization

Depending on your data, you may need to use different strategies on different columns:

- For names and other “direct identifiers”, faking is often useful
- Shuffling is convenient for foreign keys
- Adding noise is interesting for numeric values and dates
- Partial scrambling is perfect for email addresses and phone numbers

G.1.6.1. Deletion

First of all, the fastest and safest way to anonymize a data is to delete it.

In many cases, the best approach to hide the content of a column is to replace all the values with a single static value.

For instance, you can replace an entire column with the word `CONFIDENTIAL` like this:

```
SECURITY LABEL FOR anon
  ON COLUMN users.address
  IS 'MASKED WITH VALUE $$CONFIDENTIAL$$';
```

G.1.6.2. Adding Noise

This is also called *Variance*. The idea is to "shift" dates and numeric values. For example, by applying a +/- 10% variance to a salary column, the dataset will remain meaningful.

`anon.noise(`*`noise_value`* `anyelement, `*`ratio`* `double precision)`

If *`ratio`* is 0.33, the return value will be the original value randomly shifted with a ratio of +/- 33%.

`anon.dnoise(`*`noise_value`* `anyelement, `*`noise_range`* `interval)`

If *`interval`* = "2 days", the return value will be the original value randomly shifted by +/- 2 days.

> **Important**
>
> The `noise()` masking functions are vulnerable to a form of repeat attack, especially with Dynamic Masking. A masked user can guess an original value by requesting its masked value multiple times and then simply use the `avg()` function to get a close approximation. In a nutshell, these functions are best fitted for Anonymous Dumps and Static Masking. They should be avoided when using Dynamic Masking.

G.1.6.3. Randomization

The extension provides a large choice of functions to generate purely random data:

G.1.6.3.1. Basic Random values

`anon.random_date()`

Returns a `date`.

`random_date_between(`*`d1`* `date, `*`d2`* `date)`

Returns a `date` between *`d1`* and *`d2`*.

`random_int_between(`*`i1`* `integer, `*`i2`* `integer)`

Returns an `integer` between *`i1`* and *`i2`*.

`random_bigint_between(`*`b1`* `bigint, `*`b2`* `bigint)`

Returns a `bigint` between *`b1`* and *`b2`*.

`anon.random_string(`*`n`* `integer)`

Returns a `text` value containing `n` letters.

`anon.random_zip()`

Returns a 5-digit code.

`anon.random_phone(`*`phone_prefix`* `text)`

Returns an 8-digit phone with `phone_prefix` as a prefix.

`anon.random_in(ARRAY[1,2,3])`

Returns an integer between `1` and `3`.

`anon.random_in(ARRAY['red','green','blue'])`

Returns a random text value from an array of ['red', 'green', 'blue'].

G.1.6.4. Faking

The idea of *Faking* is to replace sensitive data with *random-but-plausible* values. The goal is to avoid any identification from the data record while remaining suitable for testing, data analysis and data processing.

The following faking functions are available:

`anon.fake_address()`

Returns a complete postal address.

`anon.fake_city()`

Returns an existing city.

`anon.fake_country()`

Returns an existing country.

`anon.fake_company()`

Returns a generic company name.

`anon.fake_email()`

Returns a valid email address.

`anon.fake_first_name()`

Returns a generic first name.

`anon.fake_iban()`

Returns a valid IBAN.

`anon.fake_last_name()`

Returns a generic last name.

`anon.fake_postcode()`

Returns a valid zip code.

For `text` and `varchar` columns, you can use the classic *Lorem Ipsum* generator:

`anon.lorem_ipsum()`

Returns five paragraphs.

`anon.lorem_ipsum(2)`

Returns two paragraphs.

`anon.lorem_ipsum( paragraphs := 4 )`

Returns four paragraphs.

`anon.lorem_ipsum( words := 20 )`

Returns 20 words.

`anon.lorem_ipsum( characters := LENGTH(table.column) )`

Returns the same number of characters as the original string.

G.1.6.5. Advanced Faking

Generating fake data is a complex topic. The functions provided here are limited to basic use case. For more advanced faking methods, in particular if you are looking for *localized fake data*, take a look at *PostgreSQL Faker*, an extension based upon the well-known *Faker Python library*.

This extension provides an advanced faking engine with localization support.

For example:

```
CREATE SCHEMA faker;
CREATE EXTENSION faker SCHEMA faker;
SELECT faker.faker('de_DE');
SELECT faker.first_name_female();
 first_name_female
-------------------
 Mirja
```

G.1.6.6. Pseudonymization

Pseudonymization is similar to Faking in the sense that it generates realistic values. The main difference is that the pseudonymization is deterministic: the functions will always return the same fake value based on a seed and an optional salt.

The following pseudonymization functions are available:

`anon.pseudo_first_name(`*`seed`* `anyelement,` *`salt`* `text)`

Returns a generic first name.

`anon.pseudo_last_name(`*`seed`* `anyelement,` *`salt`* `text)`

Returns a generic last name.

`anon.pseudo_email(`*`seed`* `anyelement,` *`salt`* `text)`

Returns a valid email address.

`anon.pseudo_city(`*`seed`* `anyelement,` *`salt`* `text)`

Returns an existing city.

`anon.pseudo_country(`*`seed`* `anyelement,` *`salt`* `text)`

Returns an existing country.

`anon.pseudo_company(`*`seed`* `anyelement,` *`salt`* `text)`

Returns a generic company name.

`anon.pseudo_iban(`*`seed`* `anyelement,` *`salt`* `text)`

Returns a valid IBAN.

The second argument (*`salt`*) is optional. You can call each function only with the seed like this: `anon.pseudo_city('bob')`. The salt is here to increase complexity and avoid dictionary and brute force attacks. If a salt is not given, a random secret salt is used instead (see Generic Hashing for more details).

The seed can be any information related to the subject. For instance, we can consistently generate the same fake email address for a given person by using her login as the seed:

```
SECURITY LABEL FOR anon
  ON COLUMN users.emailaddress
```

```
IS 'MASKED WITH FUNCTION anon.pseudo_email(users.login)';
```

> **Note**
>
> You may want to produce unique values using a pseudonymization function. For instance, if you want to mask an `email` column that is declared as `UNIQUE`. In this case, you will need to initialize the extension with a fake dataset that is *way bigger* than the number of rows of the table. Otherwise, you may see some "collisions" happening, i.e. two different original values producing the same pseudo value.

> **Important**
>
> Pseudonymization is often confused with anonymization but in fact they serve two different purposes: pseudonymization is a way to *protect* the personal information but the pseudonymized data is still "linked" to the real data.

G.1.6.7. Generic Hashing

In theory, hashing is not a valid anonymization technique, however in practice it is sometimes necessary to generate a determinist hash of the original data.

For instance, when a pair of primary key / foreign key is a "natural key", it may contain actual information (like a customer number containing a birth date or something similar).

Hashing such columns allows to keep referential integrity intact even for relatively unusual source data.

`anon.hash(`*`value`* `text)`

Returns a text hash of the value using a secret salt and hash algorithm.

`anon.digest(`*`value`* `text, `*`salt`* `text, `*`algorithm`* `text)`

Lets you choose a salt and a hash algorithm. Supported algorithms are: `md5`, `sha1`, `sha224`, `sha256`, `sha384`, and `sha512`.

By default, a random secret salt is generated when the extension is initialized, and the default hash algorithm is `sha512`. You can change these for the entire database with the following functions:

`anon.set_secret_salt(`*`value`* `text)`

Define your own salt.

`anon.set_algorithm(`*`value`* `text)`

Select another hash algorithm. For the list of supported algorithms, see `anon.digest`.

Keep in mind that hashing is a form of Pseudonymization. This means that the data can be "de-anonymized" using the hashed value and the masking function. If attackers get access to these two elements, they could re-identify some persons using `brute force` or `dictionary` attacks. Therefore, *the salt and the algorithm used to hash the data must be protected with the same level of security as the original dataset*.

In a nutshell, we recommend that you use the `anon.hash()` function rather than `anon.digest()` because the salt will not appear clearly in the masking rule.

Furthermore, in practice the hash function will return a long string of character like this:

```
SELECT anon.hash('bob');
                                  hash
-----------------------------------------------------------------------------------------
```

```
95b6accef02c5a725a8c9abf19ab5575f99ca3d9997984181e4b3f81d96cbca4d0977d694ac490350e01d0d21363
```

For some columns, this may be too long and you may have to cut some parts of the hash in order to fit into the column. For instance, if you have a foreign key based on a phone number and the column is a `varchar(12)`, you can transform the data like this:

```
SECURITY LABEL FOR anon ON COLUMN people.phone_number
IS 'MASKED WITH FUNCTION pg_catalog.left(anon.hash(phone_number),12)';

SECURITY LABEL FOR anon ON COLUMN call_history.fk_phone_number
IS 'MASKED WITH FUNCTION pg_catalog.left(anon.hash(fk_phone_number),12)';
```

Of course, cutting the hash value to 12 characters will increase the risk of “collision” (2 different values having the same fake hash). In such case, it's up to you to evaluate this risk.

G.1.6.8. Partial Scrambling

Partial scrambling leaves out some part of the data. For instance, a credit card number can be replaced by “40XX XXXX XXXX XX96”.

`anon.partial(`*`input`* `text, `*`prefix`* `int, `*`padding`* `text, `*`suffix`* `int)`

Partially replaces a given text. For example, `anon.partial('abcdefgh',1,'xxxx',3)` returns `axxxxfgh`.

`anon.partial_email(`*`email`* `text)`

Partially replaces a given email. For example, `anon.partial_email('daamien@gmail.com')` returns `da******@gm******.com`.

G.1.6.9. Generalization

Generalization is the principle of replacing the original value by a range containing this value. For instance, instead of saying “Paul is 42 years old”, you would say “Paul is between 40 and 50 years old”.

> **Note**
>
> The generalization functions perform data type transformation. Therefore, it is not possible to use them with the dynamic masking engine. However, they are useful to create anonymized views. See example below.

Let's imagine a table containing health information:

```
SELECT * FROM patient;
 id |   name   |  zipcode |   birth    |    disease
----+----------+----------+------------+---------------
  1 | Alice    |    47678 | 1979-12-29 | Heart Disease
  2 | Bob      |    47678 | 1959-03-22 | Heart Disease
  3 | Caroline |    47678 | 1988-07-22 | Heart Disease
  4 | David    |    47905 | 1997-03-04 | Flu
  5 | Eleanor  |    47909 | 1999-12-15 | Heart Disease
  6 | Frank    |    47906 | 1968-07-04 | Cancer
  7 | Geri     |    47605 | 1977-10-30 | Heart Disease
  8 | Harry    |    47673 | 1978-06-13 | Cancer
  9 | Ingrid   |    47607 | 1991-12-12 | Cancer
```

We can build a view upon this table to suppress some columns (`SSN` and `name`) and generalize the zipcode and the birth date like this:

```
CREATE VIEW anonymized_patient AS
SELECT
    'REDACTED' AS lastname,
```

```
    anon.generalize_int4range(zipcode,100) AS zipcode,
    anon.generalize_tsrange(birth,'decade') AS birth,
    disease
FROM patient;
```

The anonymized table now looks like that:

```
SELECT * FROM anonymized_patient;
 lastname |   zipcode     |           birth              |    disease
----------+---------------+------------------------------+---------------
 REDACTED | [47600,47700) | ["1970-01-01","1980-01-01") | Heart Disease
 REDACTED | [47600,47700) | ["1950-01-01","1960-01-01") | Heart Disease
 REDACTED | [47600,47700) | ["1980-01-01","1990-01-01") | Heart Disease
 REDACTED | [47900,48000) | ["1990-01-01","2000-01-01") | Flu
 REDACTED | [47900,48000) | ["1990-01-01","2000-01-01") | Heart Disease
 REDACTED | [47900,48000) | ["1960-01-01","1970-01-01") | Cancer
 REDACTED | [47600,47700) | ["1970-01-01","1980-01-01") | Heart Disease
 REDACTED | [47600,47700) | ["1970-01-01","1980-01-01") | Cancer
 REDACTED | [47600,47700) | ["1990-01-01","2000-01-01") | Cancer
```

The generalized values are still useful for statistics because they remain true, but they are less accurate, and therefore reduce the risk of re-identification.

Postgres Pro offers several range data types, which are perfect for dates and numeric values.

For numeric values, the following functions are available:

```
generalize_int4range(value, step)
generalize_int8range(value, step)
generalize_numrange(value, step)
```

where *value* is the data that will be generalized, and *step* is the size of each range.

G.1.6.10. Write Your Own Masks

You can also use your own function as a mask. The function must either be destructive (like Partial Scrambling) or insert some randomness in the dataset (like Faking).

For instance, if you wrote a function `foo()` inside the schema `bar`, then you can apply it like this:

```
SECURITY LABEL FOR anon ON SCHEMA bar IS 'TRUSTED';

SECURITY LABEL FOR anon ON COLUMN player.score
IS 'MASKED WITH FUNCTION bar.foo()';
```

> **Note**
>
> The `bar` schema must be declared as `TRUSTED` by a superuser.

G.1.6.10.1. Writing a Masking Function for a JSONB Column

For complex data types, you may have to write your own function. This will be a common use case if you have to hide certain parts of a JSON field.

For example:

```
CREATE TABLE company (
  business_name TEXT,
  info JSONB
)
```

The `info` field contains unstructured data like this:

```
SELECT jsonb_pretty(info) FROM company WHERE business_name = 'Soylent Green';
           jsonb_pretty
---------------------------------
 {
     "employees": [
         {
             "lastName": "Doe",
             "firstName": "John"
         },
         {
             "lastName": "Smith",
             "firstName": "Anna"
         },
         {
             "lastName": "Jones",
             "firstName": "Peter"
         }
     ]
 }
(1 row)
```

Using the JSON functions and operators, you can walk through the keys and replace the sensitive values as needed.

```
SECURITY LABEL FOR anon ON SCHEMA custom_masks IS 'TRUSTED';

CREATE FUNCTION custom_masks.remove_last_name(j JSONB)
RETURNS JSONB
VOLATILE
LANGUAGE SQL
AS $func$
SELECT
  json_build_object(
    'employees' ,
    array_agg(
      jsonb_set(e ,'{lastName}', to_jsonb(anon.fake_last_name()))
    )
  )::JSONB
FROM jsonb_array_elements( j->'employees') e
$func$;
```

Then check that the function is working correctly:

```
SELECT custom_masks.remove_last_name(info) FROM company;
```

When it is okay, you can declare this function as the mask of the `info` field:

```
SECURITY LABEL FOR anon ON COLUMN company.info
IS 'MASKED WITH FUNCTION custom_masks.remove_last_name(info)';
```

And try it out:

```
SELECT anonymize_table('company');
SELECT jsonb_pretty(info) FROM company WHERE business_name = 'Soylent Green';
            jsonb_pretty
-------------------------------------
 {
     "employees": [                 +
         {                          +
             "lastName": "Prawdzik",+
             "firstName": "John"    +
```

```
            },                          +
            {                           +
                "lastName": "Baltazor",+
                "firstName": "Anna"     +
            },                          +
            {                           +
                "lastName": "Taylan",   +
                "firstName": "Peter"    +
            }                           +
        ]                               +
 }
(1 row)
```

This is just a quick example. As you can see, manipulating a sophisticated JSON structure with SQL is possible but it can be tricky at first. There are multiple ways of walking through the keys and updating values. You will probably have to try different approaches, depending on your real JSON data and the performance you want to reach.

G.1.7. Static Masking

Sometimes, it is useful to transform directly the original dataset. You can do that with different methods:

- Applying masking rules
- Shuffling a column
- Adding noise to a column

These methods will destroy the original data. Use with care.

G.1.7.1. Applying Masking Rules

You can permanently apply the masking rules of a database with `anon.anonymize_database()`.

Let's use a basic example:

```
CREATE TABLE customer (
  id SERIAL,
  full_name TEXT,
  birth DATE,
  employer TEXT,
  zipcode TEXT,
  fk_shop INTEGER
);

INSERT INTO customer
VALUES
(911,'Chuck Norris','1940-03-10','Texas Rangers', '75001',12),
(312,'David Hasselhoff','1952-07-17','Baywatch', '90001',423)
;

SELECT * FROM customer;
```

```
 id  |   full_name      |   birth    |    employer    | zipcode | fk_shop
-----+------------------+------------+----------------+---------+---------
 911 | Chuck Norris     | 1940-03-10 | Texas Rangers | 75001   | 12
 112 | David Hasselhoff | 1952-07-17 | Baywatch      | 90001   | 423
```

1. Declare the masking rules:

```
SECURITY LABEL FOR anon ON COLUMN customer.full_name
IS 'MASKED WITH FUNCTION anon.fake_first_name() || '' '' || anon.fake_last_name()';

SECURITY LABEL FOR anon ON COLUMN customer.employer
```

```
IS 'MASKED WITH FUNCTION anon.fake_company()';

SECURITY LABEL FOR anon ON COLUMN customer.zipcode
IS 'MASKED WITH FUNCTION anon.random_zip()';
```

2. Replace authentic data in the masked columns:

```
SELECT anon.anonymize_database();

SELECT * FROM customer;

 id  |  full_name   |   birth    |      employer       | zipcode | fk_shop
-----+--------------+------------+---------------------+---------+---------
 911 | Jesse Kosel  | 1940-03-10 | Marigold Properties | 62172   |      12
 312 | Leolin Bose  | 1952-07-17 | Inventure           | 20026   |     423
```

You can also use `anonymize_table()` and `anonymize_column()` to remove data from a subset of the database:

```
SELECT anon.anonymize_table('customer');
SELECT anon.anonymize_column('customer','zipcode');
```

> **Important**
>
> Static masking is a slow process. The principle of static masking is to update all lines of all tables containing at least one masked column. This basically means that the server will rewrite all the data on disk. Depending on the database size, the hardware and the instance configuration, it may be faster to export the anonymized data (see Anonymous Dumps) and reload it into the database.

G.1.7.2. Shuffling

Shuffling mixes values within the same columns.

`anon.shuffle_column(`*`shuffle_table`* `regclass, `*`shuffle_column`* `name, `*`primary_key`* `name)`

Rearranges all values in a given column. You need to provide the primary key of the table.

This is useful for foreign keys because referential integrity will be kept.

> **Important**
>
> `shuffle_column()` is not a masking function because it works “verticaly”: it will modify all the values of a column at once.

G.1.7.3. Adding Noise to a Column

There are also some functions that can add noise on an entire column:

`anon.add_noise_on_numeric_column(`*`table`* `regclass, `*`column`* `text, `*`ratio`* `float)`

If *`ratio`* = 0.33, all values of the column will be randomly shifted with a ratio of +/- 33%.

`anon.add_noise_on_datetime_column(`*`table`* `regclass, `*`column`* `text, `*`interval`* `interval)`

If *`interval`* = `2 days`, all values of the column will be randomly shifted by +/- 2 days.

> **Important**
>
> These noise functions are vulnerable to a form of repeat attack.

G.1.8. Dynamic Masking

You can hide some data from a role by declaring this role as a “MASKED” one. Other roles will still access the original data.

```
CREATE TABLE people (id TEXT, firstname TEXT, lastname TEXT, phone TEXT);
INSERT INTO people VALUES ('T1','Sarah', 'Connor','0609110911');
SELECT * FROM people;

SELECT * FROM people;
 id | firstname | lastname |   phone
----+-----------+----------+------------
 T1 | Sarah     | Connor   | 0609110911
(1 row)
```

1. Activate the dynamic masking engine:

   ```
   SELECT anon.start_dynamic_masking();
   ```

2. Declare a masked user:

   ```
   CREATE ROLE skynet LOGIN;
   SECURITY LABEL FOR anon ON ROLE skynet
   IS 'MASKED';
   ```

3. Declare the masking rules:

   ```
   SECURITY LABEL FOR anon ON COLUMN people.lastname
   IS 'MASKED WITH FUNCTION anon.fake_last_name()';

   SECURITY LABEL FOR anon ON COLUMN people.phone
   IS 'MASKED WITH FUNCTION anon.partial(phone,2,$$******$$,2)';
   ```

4. Connect with the masked user:

   ```
   \c - skynet
   SELECT * FROM people;
    id | firstname | lastname  |   phone
   ----+-----------+-----------+------------
    T1 | Sarah     | Stranahan | 06******11
   (1 row)
   ```

G.1.8.1. How to Change the Type of a Masked Column

When dynamic masking is activated, you are not allowed to change the datatype of a column if there's a mask upon it.

To modify a masked column, you need to temporarily switch off the masking engine like this:

```
BEGIN;
SELECT anon.stop_dynamic_masking();
ALTER TABLE people ALTER COLUMN phone TYPE VARCHAR(255);
SELECT anon.start_dynamic_masking();
COMMIT;
```

G.1.8.2. How to Drop a Masked Table

The dynamic masking engine will build *masking views* upon the masked tables. This means that it is not possible to drop a masked table directly. You will get an error like this:

```
DROP TABLE people;
psql: ERROR:  cannot drop table people because other objects depend on it
DETAIL:  view mask.company depends on table people
```

To effectively remove the table, it is necessary to add the *CASCADE* option, so that the masking view will be dropped too:

```
DROP TABLE people CASCADE;
```

G.1.8.3. How to Unmask a Role

Simply remove the security label like this:

```
SECURITY LABEL FOR anon ON ROLE bob IS NULL;
```

To unmask all masked roles at once, you can type:

```
SELECT anon.remove_masks_for_all_roles();
```

G.1.8.4. Limitations

G.1.8.4.1. Listing the Tables

Due to how the dynamic masking engine works, when a masked role tries to display the tables in psql with the `\dt` command, then psql will not show any tables.

This is because the `search_path` of the masked role is rigged.

You can try adding explicit schema you want to search, for instance:

```
\dt *.*
\dt public.*
```

G.1.8.4.2. Only One Schema

The dynamic masking system only works with one schema (by default `public`). When you start the masking engine with `start_dynamic_masking()`, you can specify the schema that will be masked as follows:

```
ALTER DATABASE foo SET anon.sourceschema TO 'sales';
```

Then open a new session to the database and type:

```
SELECT start_dynamic_masking();
```

However, static masking with `anon.anonymize()` and anonymous export with `anon.dump()` will work fine with multiple schemas.

G.1.8.4.3. Performance

Dynamic Masking is known to be very slow with some queries, especially if you try to join two tables on a masked key using hashing or pseudonymization.

G.1.8.4.4. Graphic Tools

When you are using a masked role with a graphic interface, such as DBeaver or pgAdmin, the `data` panel may produce the following error when trying to display the content of a masked table called `foo`:

```
SQL Error [42501]: ERROR: permission denied for table foo
```

This is because most of these tools will directly query the `public.foo` table instead of being “redirected” by the masking engine toward the `mask.foo` view.

In order the view the masked data with a graphic tool, you can either:

Open the SQL query panel and type `SELECT * FROM foo`

Navigate to `Database > Schemas > mask > Views > foo`

G.1.9. Anonymous Dumps

Due to the core design of this extension, you cannot use pg_dump with a masked user. If you want to export the entire database with the anonymized data, you must use the `pg_dump_anon.sh` script.

G.1.9.1. pg_dump_anon.sh

The `pg_dump_anon.sh` script supports most of the options of the regular `pg_dump` command. The environment variables (`PGHOST`, `PGUSER`, etc.) and the `.pgpass` files are also supported.

G.1.9.2. Example

A user named `bob` can export an anonymous dump of the `app` database like this:

```
/opt/pgpro/ent-16/bin/pg_dump_anon.sh -h localhost -U bob --password --
file=anonymous_dump.sql app
```

> **Important**
>
> The name of the database must be the last parameter.

For more details about the supported options, simply type `./pg_dump_anon.sh --help`.

G.1.9.3. Limitations

- The user password is asked automatically. This means you must either add the `--password` option to define it interactively or declare it in the `PGPASSWORD` variable or put it inside the `.pgpass` file (however on Windows,the `PGPASSFILE` variable must be specified explicitly)
- The `plain` format is the only supported format. The other formats (`custom`, `dir` and `tar`) are not supported.

G.1.10. Generalization

G.1.10.1. Reducing the Accuracy of Sensitive Data

The idea of generalization is to replace data with a broader, less accurate value. For instance, instead of saying “Bob is 28 years old”, you can say “Bob is between 20 and 30 years old”. This is interesting for analytics because the data remains true while avoiding the risk of re-identification.

Generalization is a way to achieve k-anonymity.

Postgres Pro can handle generalization very easily with the range data types, a very powerful way to store and manipulate a set of values contained between a lower and an upper bound.

G.1.10.2. Example

Here's a basic table containing medical data:

```
SELECT * FROM patient;
     ssn      | firstname | zipcode |   birth    |    disease
--------------+-----------+---------+------------+---------------
 253-51-6170 | Alice     |   47012 | 1989-12-29 | Heart Disease
 091-20-0543 | Bob       |   42678 | 1979-03-22 | Allergy
 565-94-1926 | Caroline  |   42678 | 1971-07-22 | Heart Disease
 510-56-7882 | Eleanor   |   47909 | 1989-12-15 | Acne
 098-24-5548 | David     |   47905 | 1997-03-04 | Flu
 118-49-5228 | Jean      |   47511 | 1993-09-14 | Flu
 263-50-7396 | Tim       |   47900 | 1981-02-25 | Heart Disease
 109-99-6362 | Bernard   |   47168 | 1992-01-03 | Asthma
 287-17-2794 | Sophie    |   42020 | 1972-07-14 | Asthma
 409-28-2014 | Arnold    |   47000 | 1999-11-20 | Diabetes
```

```
(10 rows)
```

We want the anonymized data to remain *true* because it will be used for statistics. We can build a view upon this table to remove useless columns and generalize the indirect identifiers:

```
CREATE MATERIALIZED VIEW generalized_patient AS
SELECT
  'REDACTED'::TEXT AS firstname,
  anon.generalize_int4range(zipcode,1000) AS zipcode,
  anon.generalize_daterange(birth,'decade') AS birth,
  disease
FROM patient;
```

This will give us a less accurate view of the data:

```
SELECT * FROM generalized_patient;
 firstname |    zipcode    |          birth          |    disease
-----------+---------------+-------------------------+---------------
 REDACTED  | [47000,48000) | [1980-01-01,1990-01-01) | Heart Disease
 REDACTED  | [42000,43000) | [1970-01-01,1980-01-01) | Allergy
 REDACTED  | [42000,43000) | [1970-01-01,1980-01-01) | Heart Disease
 REDACTED  | [47000,48000) | [1980-01-01,1990-01-01) | Acne
 REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Flu
 REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Flu
 REDACTED  | [47000,48000) | [1980-01-01,1990-01-01) | Heart Disease
 REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Asthma
 REDACTED  | [42000,43000) | [1970-01-01,1980-01-01) | Asthma
 REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Diabetes
(10 rows)
```

G.1.10.3. Generalization Functions

`pgpro_anonymizer` provides generalization functions, one for each range type. Generally, these functions take the original value as the first parameter, and a second parameter for the length of each step.

For numeric values:

`anon.generalize_int4range(`*`value`* `integer, `*`step`* `integer)`

For example, `anon.generalize_int4range(42,5)` returns the range `[40,45)`.

`anon.generalize_int8range(`*`value`* `integer, `*`step`* `integer)`

For example, `anon.generalize_int8range(12345,1000)` returns the range `[12000,13000)`.

`anon.generalize_numrange(`*`value`* `integer, `*`step`* `integer)`

For example, `anon.generalize_numrange(42.32378,10)` returns the range `[40,50)`.

For time values:

`anon.generalize_tsrange(`*`value`* `integer, `*`step`* `integer)`

For example, `anon.generalize_tsrange('1904-11-07','year')` returns `['1904-01-01','1905-01-01')`.

`anon.generalize_tstzrange(`*`value`* `integer, `*`step`* `integer)`

For example, `anon.generalize_tstzrange('1904-11-07','week')` returns `['1904-11-07','1904-11-14')`.

`anon.generalize_daterange(`*`value`* `integer, `*`step`* `integer)`

For example, `anon.generalize_daterange('1904-11-07','decade')` returns `[1900-01-01,1910-01-01)`.

The possible steps are: microsecond, millisecond, second, minute, hour, day, week, month, year, decade, century and millennium.

G.1.10.4. Limitations

G.1.10.4.1. Singling Out and Extreme Values

Singling Out is the possibility to isolate an individual in a dataset by using extreme value or exceptional values.

For example:

```
SELECT * FROM employees;

  id  |  name           | job  | salary
------+-----------------+------+--------
 1578 | xkjefus3sfzd    | NULL |    1498
 2552 | cksnd2se5dfa    | NULL |    2257
 5301 | fnefckndc2xn    | NULL |   45489
 7114 | npodn5ltyp3d    | NULL |    1821
```

In this table, we can see that a particular employee has a very high salary, very far from the average salary. Therefore this person is probably the CEO of the company.

With generalization, this is important because the size of the range (the “step”) must be wide enough to prevent the identification of one single individual.

k-anonymity is a way to assess this risk.

G.1.10.4.2. Generalization is Not Compatible with Dynamic Masking

By definition, with generalization the data remains true, but the column type is changed.

This means that the transformation is not transparent, and therefore it cannot be used with dynamic masking.

G.1.10.5. k-anonymity

k-anonymity is an industry-standard term used to describe a property of an anonymized dataset. The k-anonymity principle states that within a given dataset, any anonymized individual cannot be distinguished from at least `k-1` other individuals. In other words, k-anonymity might be described as a “hiding in the crowd” guarantee. A low value of `k` indicates there's a risk of re-identification using linkage with other data sources.

`anon.k_anonymity(`*`id`* `regclass)`

You can evaluate the k-anonymity factor of a table as follows:

1. Define the columns that are indirect identifiers (also known as *quasi identifiers*) like this:

   ```
   SECURITY LABEL FOR anon ON COLUMN patient.firstname
   IS 'INDIRECT IDENTIFIER';

   SECURITY LABEL FOR anon ON COLUMN patient.zipcode
   IS 'INDIRECT IDENTIFIER';

   SECURITY LABEL FOR anon ON COLUMN patient.birth
   IS 'INDIRECT IDENTIFIER';
   ```

2. Once the indirect identifiers are declared:

   ```
   SELECT anon.k_anonymity('generalized_patient')
   ```

   The higher the value, the better.

G.1.11. Performance

Any anonymization process has a price as it will consume CPU time, RAM space and probably a lot of disk I/O. Here's a quick overview of the question depending on the strategy you are using.

In a nutshell, the anonymization performance mainly depends on the following important factors:

- The size of the database
- The number of masking rules

G.1.11.1. Static Masking

Basically what static masking does it rewrite entirely the masked tables on disk. This may be slow depending on your environment. And during this process, the tables will be locked.

> **Note**
>
> In this case, the cost of anonymization is “paid” by all the users but it is paid *once and for all*.

G.1.11.2. Dynamic Masking

With dynamic masking, the real data is replaced on-the-fly **every time** a masked user sends a query to the database. This means that the masking users will have slower response time than regular (unmasked) users. This is generally ok because usually masked users are not considered as important as the regular ones.

If you apply three or four rules to a table, the response time for the masked users should be approximately 20% to 30% slower than for the normal users.

As the masking rules are applied for each queries of the masked users, the dynamic masking is appropriate when you have a limited number of masked users that connect only from time to time to the database. For instance, a data analyst connecting once a week to generate a business report.

If there are multiple masked users or if a masked user is very active, you should probably export the masked data once-a-week on a secondary instance and let these users connect to this secondary instance.

> **Note**
>
> In this case, the cost of anonymization is “paid” only by the masked users.

G.1.11.3. Anonymous Dumps

If the backup process of your database takes one hour with `pg_dump`, then anonymizing and exporting the entire database with `pg_dump_anon.sh` will probably take two hours.

> **Note**
>
> In this case, the cost of anonymization is “paid” by the user asking for the anonymous export. Other users of the database will not be affected.

G.1.11.4. How to Speed Things Up

G.1.11.4.1. Prefer `MASKED WITH VALUE` Whenever Possible

It is always faster to replace the original data with a static value instead of calling a masking function.

G.1.11.4.2. Materialized Views

Dynamic masking is not always required. In some cases, it is more efficient to build Materialized Views instead.

For instance:

```
CREATE MATERIALIZED VIEW masked_customer AS
SELECT
    id,
    anon.random_last_name() AS name,
    anon.random_date_between('1920-01-01'::DATE,now()) AS birth,
    fk_last_order,
    store_id
FROM customer;
```

G.1.12. Security

G.1.12.1. Permissions

Here's an overview of what users can do depending on the privilege they have:

Table G.1. Privileges

Action	Superuser	Owner	Masked Role
Create the extension	Yes		
Drop the extension	Yes		
Init the extension	Yes		
Reset the extension	Yes		
Configure the extension	Yes		
Put a mask upon a role	Yes		
Start dynamic masking	Yes		
Stop dynamic masking	Yes		
Create a table	Yes	Yes	
Declare a masking rule	Yes	Yes	
Insert, delete, update a row	Yes	Yes	
Use static masking	Yes	Yes	
Select the real data	Yes	Yes	
Use regular dumps	Yes	Yes	
Use anonymous dumps	Yes	Yes	
Use the masking functions	Yes	Yes	Yes
Select the masked data	Yes	Yes	Yes
View the masking rules	Yes	Yes	Yes

G.1.12.2. Limit Masking Filters Only to Trusted Schemas

Database owners are allowed to declare masking rules. They can also create functions containing arbitrary code and use these function inside masking rules. In certain circumstances, the database owner can “trick” a superuser into querying a masked table and thus executing the arbitrary code.

To prevent this, superusers can configure the parameter below:

```
anon.restrict_to_trusted_schemas = on
```

With this setting, the database owner can only write masking rules with functions that are located in the trusted schemas which are controlled by superusers.

G.1.12.3. Security Context of the Functions

Most of the functions of this extension are declared with the `SECURITY INVOKER` tag. This means that these functions are executed with the privileges of the user that calls them. This is an important restriction.

This extension contains another few functions declared with the tag `SECURITY DEFINER`.

G.2. pgpro_datactl — manage Postgres Pro Enterprise data files

G.2.1. Overview

The pgpro_datactl utility provides tools for managing Postgres Pro Enterprise data files, including a module for CFS (Compressed File Storage) operations. This module offers the following functionalities:

- Retrieving metadata from compressed files, including their compression algorithm and location.
- Unpacking CFS files for further analysis.

G.2.2. Installation

pgpro_datactl is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-datactl-ent-16` (for the detailed installation instructions, see Chapter 17).

G.2.3. Commands

pgpro_datactl supports the following commands:

- `unpack`
- `probe`
- `info`

G.2.3.1. unpack

```
pgpro_datactl unpack --source=source_path --target=target_path
[--calg=compression_algorithm] [-verbose] [--log-level=logging_level] [--help]
```

Unpacks CFS files.

`-s=source_path`
`--source=source_path`

Specifies the path to a compressed file or directory.

> **Note**
>
> The path must be in the directory named `PG_version_date` that contains the `pg_compression` file.

`-t=target_path`
`--target=target_path`

Specifies the path to a directory where the unpacked files will be placed.

If the source and target directories are the same, files are unpacked with a `.dec` extension.

`-c=`*`compression_algorithm`*
`--calg=`*`compression_algorithm`*

Specifies the compression algorithm used. If omitted, the `unpack` command will take this value from the `pg_compression` file.

`-v`
`--verbose`

Enables detailed logging.

`--log-level=`*`logging_level`*

Sets the logging level. Possible values: `info`, `warning`, `error`.

Example:

```
pgpro_datactl unpack -s /path/to/archive.cfs -t /path/to/destination -c zstd
```

In this example, `unpack` extracts `archive.cfs` compressed with the `zstd` algorithm into the directory `/path/to/destination`.

G.2.3.2. probe

`pgpro_datactl probe --source=`*`source_path`* `[--log-level=`*`logging_level`*`] [--help]`

Analyzes the specified file and identifies the following:

- Compression type: `zlib` or `zstd` compression algorithm.
- Fragmentation level: Analyzes the corresponding `*.cfm` file (if available) and reports the percentage of unused storage space in the physical file.
- Whether the file belongs to CFS: Checks the presence of an associated `*.cfm` file, which indicates whether the file belongs to a CFS archive.

`-s=`*`source_path`*
`--source=`*`source_path`*

Specifies the path to the target file.

`--log-level=`*`logging_level`*

Sets the logging level. Possible values: `info`, `warning`, `error`.

Example output:

```
Probing path: /data/sample.dat
Has cfm file: Yes
pg_compression: zstd
Actual compression: zstd
Fragmentation: 5%
```

In this example, the file is compressed with the `zstd` algorithm, is part of a CFS archive, and has a fragmentation level of five percent.

G.2.3.3. info

`pgpro_datactl info --source=`*`source_path`* `[--log-level=`*`logging_level`*`] [--help]`

Analyzes the file and displays the following information:

- The file physical size, virtual size, and utilized file space in bytes.
- Whether the garbage collector (`GC`) is active.
- Whether the `*.cfm` file is present and accessible.

`-s=`*source_path*
`--source=`*source_path*

Specifies the path to the target file.

`--log-level=`*logging_level*

Sets the logging level. Possible values: `info`, `warning`, `error`.

Example output:

```
Physical size: 10485760
Virtual size: 9437184
Used size: 7864320
GC active: Yes
```

G.3. pgpro_multiplan — save a specific plan of a parameterized query for future usage

G.3.1. Description

pgpro_multiplan allows the user to save query execution plans and utilize these plans for subsequent executions of the same queries, thereby avoiding repeated optimization of identical queries.

pgpro_multiplan looks like Oracle Outline system. It can be used to lock the execution plan. It could help if you do not trust the planner.

G.3.2. Installation

The pgpro_multiplan extension is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-multiplan-ent-16` (for the detailed installation instructions, see Chapter 17). To enable pgpro_multiplan, complete the following steps:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'pgpro_multiplan'
   ```

   Note that the library names in the `shared_preload_libraries` variable must be added in the specific order, for information on compatibility of pgpro_multiplan with other extensions, see Section G.3.6.

2. Reload the database server for the changes to take effect.

   To verify that the `pgpro_multiplan` library was installed correctly, you can run the following command:

   ```
   SHOW shared_preload_libraries;
   ```

3. Create the `pgpro_multiplan` extension using the following query:

   ```
   CREATE EXTENSION pgpro_multiplan;
   ```

   It is essential that the library is preloaded during server startup because pgpro_multiplan has a shared memory cache that can be initialized only during startup. The pgpro_multiplan extension should be created in each database where query management is required.

4. Enable the pgpro_multiplan extension, which is disabled by default, in one of the following ways:

   - To enable pgpro_multiplan for all backends, set `pgpro_multiplan.enable = true` in the `postgresql.conf` file.
   - To activate pgpro_multiplan in the current session, use the following command:

     ```
     SET pgpro_multiplan.enable TO true;
     ```

5. If you want to transfer pgpro_multiplan data from the primary to a standby using physical replication, set the pgpro_multiplan.wal_rw parameter to `on` on both servers. In this case, ensure that the same pgpro_multiplan versions are installed on both primary and standby, otherwise correct replication workflow is not guaranteed.

G.3.3. Usage

There are two ways to use pgpro_multiplan: either with frozen plans or with allowed plans.

G.3.3.1. Frozen Plans

pgpro_multiplan allows you to freeze plans for future usage. Freezing involves three stages:

1. Registering the query for which you want to freeze the plan.
2. Modifying the query execution plan.
3. Freezing the query execution plan.

G.3.3.1.1. Registering a Query

There are two ways to register a query:

- Using the pgpro_multiplan_register_query() function:

  ```
  SELECT pgpro_multiplan_register_query(query_string, parameter_type, ...);
  ```

  Here *query_string* is your query with `$n` parameters (same as in `PREPARE statement_name AS`). You can describe each parameter type with the optional *parameter_type* argument of the function or choose not to define parameter types explicitly. In the latter case, Postgres Pro attempts to determine each parameter type from the context. This function returns the unique pair of `sql_hash` and `const_hash`. Now pgpro_multiplan will track executions of queries that fit the saved parameterized query template.

  ```
  -- Create table 'a'
  CREATE TABLE a AS (SELECT * FROM generate_series(1,30) AS x);
  CREATE INDEX ON a(x);
  ANALYZE;

  -- Register the query
  SELECT sql_hash, const_hash
  FROM pgpro_multiplan_register_query('SELECT count(*) FROM a
  WHERE x = 1 OR (x > $2 AND x < $1) OR x = $1', 'int', 'int');
         sql_hash         | const_hash
  ------------------------+------------
    -6037606140259443514 | 2413041345
  (1 row)
  ```

- Using the pgpro_multiplan.auto_tracking parameter:

  ```
  -- Set pgpro_multiplan.auto_tracking to on
  SET pgpro_multiplan.auto_tracking = on;

  -- Execute EXPLAIN for a non-parameterized query

  EXPLAIN SELECT count(*) FROM a WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

  Custom Scan (MultiplanScan)  (cost=1.60..0.00 rows=1 width=8)
    Plan is: tracked
    SQL hash: 5393873830515778388
    Const hash: 0
    Plan hash: 0
    ->  Aggregate  (cost=1.60..1.61 rows=1 width=8)
          ->  Seq Scan on a  (cost=0.00..1.60 rows=2 width=0)
  ```

```
Filter: ((x = $1) OR ((x > $2) AND (x < $3)) OR (x = $4))
```

G.3.3.1.2. Modifying the Query Execution Plan

A query execution plan can be modified using optimizer variables, pg_hint_plan hints if the extension is enabled, or other extensions that allow changing the query plan, such as aqo. For information on compatibility of pgpro_multiplan with other extensions, see Section G.3.6.

G.3.3.1.3. Freezing the Query Execution Plan

To freeze a modified query plan, use the pgpro_multiplan_freeze function. The optional parameter *plan_type* can be set to either `serialized` or `hintset`. The default value is `serialized`. For detailed information on types of frozen plans, see Section G.3.4.

G.3.3.1.4. Frozen Plan Example

The below example illustrates the usage of the frozen plan.

```
-- A plan that needs to be improved
EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a
WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

                                QUERY PLAN
-------------------------------------------------------------------------
Aggregate (actual rows=1 loops=1)
   ->  Seq Scan on a (actual rows=12 loops=1)
         Filter: ((x = 1) OR ((x > 11) AND (x < 22)) OR (x = 22))
         Rows Removed by Filter: 18
Planning Time: 0.179 ms
Execution Time: 0.069 ms
(6 rows)

-- Make sure pgpro_multiplan is enabled
SET pgpro_multiplan.enable = 'on';

-- Register the query
SELECT sql_hash, const_hash
FROM pgpro_multiplan_register_query('SELECT count(*) FROM a
WHERE x = 1 OR (x > $2 AND x < $1) OR x = $1', 'int', 'int');

G.3.3.2. Allowed Plans

If there is no frozen plan for the given query, the pgpro_multiplan extension can apply a plan from the set of *allowed plans* created by the standard planner or real-time query replanning.

To add plans produced by real-time query replanning to the list of allowed plans automatically, enable real-time query replanning and set the pgpro_multiplan.aqe_plans_auto_approve parameter to `on`.

To add the plan created by the standard planner to the set of allowed plans, follow these steps:

- Capture the plan
- Approve the plan

For subsequent queries, the created plan is applied without modification if it is in the set of allowed plans. If there is no such plan, the cheapest plan from the set of allowed plans is used.

> **Note**
>
> Allowed plans can be used only when pg_hint_plan extension is active, see Frozen Plan Types and Compatibility with Other Extensions sections. Allowed plans are not used if automatic capturing is

enabled. Do not forget to disable the pgpro_multiplan.auto_capturing parameter after completing the capture.

G.3.3.2.1. Capturing a Plan

The pgpro_multiplan.auto_capturing parameter allows capturing all executed queries.

```
-- Create table 'a'
CREATE TABLE a AS SELECT x, x AS y FROM generate_series(1,1000) x;
CREATE INDEX ON a(x);
CREATE INDEX ON a(y);
ANALYZE;

-- Enable the auto_capturing parameter
SET pgpro_multiplan.auto_capturing = 'on';
SET pgpro_multiplan.enable = 'on';

-- Execute the query
SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 1000 AND t2.y > 900;
count
-------
100
(1 row)

-- Execute it again with different constants to get a different plan
SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 10 AND t2.y > 900;
count
-------
0
(1 row)

-- Now you can see the captured plans using the corresponding view
SELECT * FROM pgpro_multiplan_captured_queries \gx

Planning Time: 2.473 ms
Execution Time: 1.859 ms
(16 rows)
```

G.3.4. Frozen Plan Types

There are three types of frozen plans: serialized plans, hint-set plans, and template plans.

- A `serialized` plan is a serialized representation of the plan. This plan is transformed into an executable plan upon the first match of the corresponding frozen query. The serialized plan remains valid as long as the query metadata (table structures, indexes, etc.) remain unchanged. For example, if a table present in the frozen plan is recreated, the frozen plan becomes invalid and is ignored. The serialized plan is only valid within the current database and cannot be copied to another, as it depends on OIDs. For this reason, using a serialized plan for temporary tables is impractical.

- A `hintset` plan is a set of hints that are formed based on the execution plan at the time of freezing. The set of hints consists of optimizer environment variables differing from default values, join types, join orders, and data access methods. These hints correspond to those supported by the pg_hint_plan extension. To use hint-set plans, pg_hint_plan must be enabled. The set of hints is passed to the pg_hint_plan planner upon the first match of the corresponding frozen query, and pg_hint_plan generates the executable plan. If the pg_hint_plan extension is not active, the hints are ignored, and the plan generated by the Postgres Pro optimizer is executed. Hint-set plans do not depend on object identifiers and remain valid when tables are recreated, fields are added, etc. Currently the allowed plans can have only the `hintset` type.
- A `template` plan is a special case of a `hintset` plan. If the same `POSIX` regular expressions are used for mapping the table names in queries and the frozen query, the `template` plan is used.

G.3.5. Frozen Plan Backups

The pgpro_multiplan extension allows you to create a backup of frozen plans and then restore these plans into the current database. This can be useful to transfer plans between databases or server instances.

To back up frozen plans from a specific database, use the `pgpro_multiplan_storage` view like this:

```
CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

To restore frozen plans from a backup, call the `pgpro_multiplan_restore()` function:

```
SELECT s.query_string, res.sql_hash IS NOT NULL AS success
FROM storage_copy s,
LATERAL pgpro_multiplan_restore(s.query_string, s.hintstr, s.paramtypes, s.plan_type)
 res;
```

> **Note**
>
> Plans can be restored only when the pg_hint_plan extension is active, see the Compatibility with Other Extensions section.
>
> Plans are always restored into the current database. To restore plans into another database, connect to it first. Thus, it is recommended to create a backup with plans only from one required database as for *db_name* in the examples in this section. If you need to transfer plans for multiple databases, create separate backups for them, connect to each target database sequentially one by one, and restore the corresponding plans from backups.

G.3.5.1. Limitations

When you back up and restore plans, take into account the following limitations:

- Only frozen plans can be restored.
- Frozen plans of the `template` type cannot be restored. Only `serialized` and `hintset` plans are supported.
- If you back up plans from multiple databases and those databases contain different frozen plans for identical queries, only the first conflicting plan will be restored.
- Only plans for valid queries can be restored, which means that all relations used in the query must exist in the current database.

G.3.5.2. Use Cases

This section describes how to back up and restore frozen plans in different popular scenarios.

G.3.5.2.1. Upgrading a Server Version

Follow the steps below to save frozen plans when upgrading a server from an older version that has an incompatible data storage.

1. Back up frozen plans before upgrade.

```
CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

2. Upgrade the server.
3. Restore frozen plans.

```
SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;
```

G.3.5.2.2. Transferring Plans Between Server Instances

To transfer frozen plans between two servers, do the following:

1. Connect to the source server.
2. Back up frozen plans to a table.

```
CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

3. Use the pg_dump utility to dump the table to a file.

```
$ pg_dump --table storage_copy -Ft postgres > storage_copy.tar
```

4. Connect to the target server and connect to the required database.
5. Move the created dump file to the target file system.
6. Use the pg_restore utility to restore the table with frozen plans from the dump file.

```
$ pg_restore --dbname postgres -Ft storage_copy.tar
```

7. Restore frozen plans.

```
SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;

DROP TABLE storage_copy;
```

G.3.5.2.3. Transferring Plans From the Sandbox to the Regular Storage

To transfer frozen plans from the sandbox to the regular storage, complete the following steps:

1. Set the pgpro_multiplan.sandbox parameter to `on` and back up frozen plans from the sandbox.

```
SET pgpro_multiplan.sandbox = ON;

CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

2. Set the *pgpro_multiplan.sandbox* parameter to `off` and restore frozen plans into the regular storage.

```
SET pgpro_multiplan.sandbox = OFF;
```

```
SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;
```

G.3.5.2.4. Transferring Plans Between Databases

To transfer frozen plans from one database to another, connect to the target database and restore plans as shown below.

```
SELECT pgpro_multiplan_restore(s.query_string, s.hintstr, s.paramtypes, s.plan_type)
FROM pgpro_multiplan_storage s JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

Here *db_name* is the name of the database from which you want to transfer plans.

G.3.5.2.5. Example of Transferring Plans

This example demonstrates how to transfer plans from one server instance to another.

```
-- Connect to the source server
psql (17.4)
Type "help" for help.

-- In this example, 1000 plans are stored in the pgpro_multiplan_storage view
postgres=# select count(*) from pgpro_multiplan_storage;
  count
-------
  1000
(1 row)

-- Copy frozen plans from the postgres database to a table
postgres=# CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'postgres';

-- Dump the table to an archive file
$ pg_dump --table storage_copy -Ft postgres > storage_copy.tar

-- Close the connection to the source server
-- Connect to the target server
./psql postgres
psql (16.8)
Type "help" for help.

-- Create the pgpro_multiplan extension and enable it
postgres=# create extension pgpro_multiplan;
CREATE EXTENSION
SET pgpro_multiplan.enable TO true;
SET

-- This server does not contain frozen plans
postgres=# select count(*) from pgpro_multiplan_storage;
 count
-------
     0
(1 row)

-- Move the dump file with frozen plans to the target file system

-- Restore the table with frozen plans from the dump
```

```
$ pg_restore --dbname postgres -Ft storage_copy.tar

-- Restore frozen plans from the table using the pgpro_multiplan_restore function
postgres=# SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;
     pgpro_multiplan_restore
---------------------------------
 (8436876698844323073,871432885)
 (8436876698844323073,573678316)
 (8436876698844323073,1999378082)
 (8436876698844323073,1681603536)
 (8436876698844323073,3959620774)
...
 (8436876698844323073,1263226437)
 (8436876698844323073,4053700861)
 (8436876698844323073,2418458596)
 (8436876698844323073,413896030)
(1000 rows)

-- The function restores 1000 frozen plans. The result is shown as pairs of sql_hash
 and const_hash
-- Frozen queries were identical and differed only in constants, so sql_hash is the
 same for all plans

-- Drop the table used to restore plans
postgres=# DROP TABLE storage_copy;
DROP TABLE

-- The target server now also stores 1000 frozen plans
postgres=# select count(*) from pgpro_multiplan_storage;
 count
-------
  1000
(1 row)

-- Disable pgpro_multiplan and run the query
postgres=# SET pgpro_multiplan.enable = OFF;
SET
postgres=# EXPLAIN (COSTS OFF) SELECT * FROM a WHERE x > 10;
     QUERY PLAN
--------------------
 Seq Scan on a
   Filter: (x > 10)
(2 rows)

-- Enable pgpro_multiplan and run the same query once again
-- One of the restored plans is now used
postgres=# SET pgpro_multiplan.enable = ON;
SET
postgres=# EXPLAIN (COSTS OFF) SELECT * FROM a WHERE x > 10;
             QUERY PLAN
-------------------------------------
 Custom Scan (MultiplanScan)
   Plan is: frozen, serialized
   SQL hash: 8436876698844323073
   Const hash: 2295408638
   Plan hash: 0
   ->  Index Scan using a_x_idx on a
```

```
          Index Cond: (x > 10)
(7 rows)
```

G.3.6. Compatibility with Other Extensions

To ensure compatibility of pgpro_multiplan with other enabled extensions, specify the library names in the `shared_preload_libraries` variable in the `postgresql.conf` file in the specific order:

- pg_hint_plan: pgpro_multiplan must be loaded after pg_hint_plan.

  ```
  shared_preload_libraries = 'pg_hint_plan, pgpro_multiplan'
  ```

- aqo: pgpro_multiplan must be loaded before aqo.

  ```
  shared_preload_libraries = 'pgpro_multiplan, aqo'
  ```

- pgpro_stats: pgpro_multiplan must be loaded after pgpro_stats.

  ```
  shared_preload_libraries = 'pgpro_stats, pgpro_multiplan'
  ```

G.3.7. Frozen Query Identification

A frozen query in the current database is identified by a combination of `sql_hash` and `const_hash`.

`sql_hash` is a hash generated based on the parse tree, ignoring parameters and constants. Field and table aliases are not ignored. Therefore, the same query with different aliases will have different `sql_hash` values.

`const_hash` is a hash generated based on all constants involved in the query. Constants with the same value but different types, such as `1` and `'1'`, will produce different hash values.

G.3.8. Automatic Type Casting

pgpro_multiplan automatically attempts to cast the types of constants involved in the query to match the parameter types of the frozen query. If type casting is not possible, the frozen plan is ignored.

```
SELECT sql_hash, const_hash
FROM pgpro_multiplan_register_query('SELECT count(*) FROM a
WHERE x = $1', 'int');

-- Type casting is possible
EXPLAIN SELECT count(*) FROM a WHERE x = '1';
                      QUERY PLAN
-------------------------------------------------------------
Custom Scan (MultiplanScan)  (cost=1.38..1.39 rows=1 width=8)
  Plan is: tracked
  SQL hash: -5166001356546372387
  Const hash: 0
  Plan hash: 0
  ->  Aggregate  (cost=1.38..1.39 rows=1 width=8)
        ->  Seq Scan on a  (cost=0.00..1.38 rows=1 width=0)
              Filter: (x = $1)

-- Type casting is possible
EXPLAIN SELECT count(*) FROM a WHERE x = 1::bigint;
                      QUERY PLAN
-------------------------------------------------------------
Custom Scan (MultiplanScan)  (cost=1.38..1.39 rows=1 width=8)
  Plan is: tracked
  SQL hash: -5166001356546372387
  Const hash: 0
  Plan hash: 0
  ->  Aggregate  (cost=1.38..1.39 rows=1 width=8)
```

```
         ->  Seq Scan on a  (cost=0.00..1.38 rows=1 width=0)
               Filter: (x = $1)

-- Type casting is impossible
EXPLAIN SELECT count(*) FROM a WHERE x = 1111111111111;
                    QUERY PLAN
------------------------------------------------------
 Aggregate  (cost=1.38..1.39 rows=1 width=8)
   ->  Seq Scan on a  (cost=0.00..1.38 rows=1 width=0)
         Filter: (x = '1111111111111'::bigint)
```

G.3.9. Individual Replanning Trigger Values

If real-time query replanning is enabled, it attempts to reoptimize queries when replanning triggers fire during query execution. Global trigger values are specified in the replan_query_execution_time, replan_overrun_limit, and replan_memory_limit configuration parameters.

The pgpro_multiplan extension allows you to override and adjust trigger values for individual queries using the `set_aqe_trigger()` function. All individual trigger values are shown in the `aqe_triggers` view.

G.3.10. Real-Time Query Replanning Statistics

The pgpro_multiplan extension can collect cumulative statistics for all statements considered feasible for real-time query replanning reoptimization. To enable this feature, set the pgpro_multiplan.aqe_collect_stats parameter to `on`. These statistics are stored in shared memory until a server shutdown and can be accessed using the `aqe_stats` view. The statistics are not replicated. The pgpro_multiplan.aqe_max_stats parameter specifies the maximum number of collected statistics values, further statistics will be discarded.

G.3.11. Views

G.3.11.1. The `pgpro_multiplan_storage` View

The `pgpro_multiplan_storage` view provides detailed information about all frozen and allowed plans. The columns of the view are shown in Table G.2.

Table G.2. `pgpro_multiplan_storage` Columns

Name	Type	Description
`dbid`	`oid`	ID of the database where the statement is executed
`sql_hash`	`bigint`	Internal query ID
`const_hash`	`bigint`	Hash of non-parameterized constants
`plan_hash`	`bigint`	Internal ID of the allowed plan, 0 for frozen plans
`valid`	`boolean`	`FALSE` if the plan was invalidated the last time it was used
`cost`	`float`	Cost of the allowed plan, 0 for frozen plans
`query_string`	`text`	Query for which the plan was frozen or approved
`paramtypes`	`regtype[]`	Array with parameter types used in the query
`query`	`text`	Internal representation of the query

Name	Type	Description
plan	text	Internal representation of the plan
plan_type	text	Plan type. For frozen plans: serialized, hintset, or template. For allowed plans: hintset
hintstr	text	Set of hints formed based on the plan
wildcards	text	Wildcards used for the template frozen plan, NULL for other plan types

G.3.11.2. The pgpro_multiplan_local_cache View

The pgpro_multiplan_local_cache view provides detailed information about registered and frozen statements in the local cache. The columns of the view are shown in Table G.3.

Table G.3. pgpro_multiplan_local_cache Columns

Name	Type	Description
sql_hash	bigint	Internal query ID
const_hash	bigint	Hash of non-parameterized constants
fs_is_frozen	boolean	TRUE if the statement is frozen
fs_is_valid	boolean	TRUE if the statement is valid
ps_is_valid	boolean	TRUE if the statement should be revalidated
query_string	text	Query registered by the pgpro_multiplan_register_query function
query	text	Internal representation of the query
paramtypes	regtype[]	Array with parameter types used in the query
hintstr	text	Set of hints formed based on the frozen plan

G.3.11.3. The pgpro_multiplan_captured_queries View

The pgpro_multiplan_captured_queries view provides detailed information about all queries captured in sessions. The columns of the view are shown in Table G.4.

Table G.4. pgpro_multiplan_captured_queries Columns

Name	Type	Description
dbid	oid	ID of the database where the statement is executed
sql_hash	bigint	Internal query ID
queryid	bigint	Standard query ID
plan_hash	bigint	Internal plan ID
cost	float	Plan cost
sample_string	text	Query executed in the automatic query capture mode

Name	Type	Description
query_string	text	Parameterized query
constants	text	Set of constants in the query
prep_consts	text	Set of constants used to EXECUTE a prepared statement
hintstr	text	Set of hints formed based on the plan
explain_plan	text	Plan shown by the EXPLAIN command

G.3.11.4. The pgpro_multiplan_fs_counter View

The pgpro_multiplan_fs_counter view provides information about frozen statements. The columns of the view are shown in Table G.5.

Table G.5. pgpro_multiplan_fs_counter Columns

Name	Type	Description
dbid	oid	ID of the database where the statement is executed
sql_hash	bigint	Internal query ID
plan_hash	bigint	Internal plan ID
usage_numb	text	Frozen statement usage counter

G.3.11.5. The aqe_triggers View

The aqe_triggers view provides information about individual replanning trigger values. The columns of the view are shown in Table G.6.

Table G.6. aqe_triggers Columns

Name	Type	Description
dbid	oid	ID of the database where the statement is executed
sql_hash	bigint	Internal query ID
execution_time	int	Value for the query execution time trigger, in milliseconds. NULL if the global trigger value is used
memory	int	Value for the backend memory consumption trigger. NULL if the global trigger value is used
underestimation_rate	double	Factor for the processed number of node tuples trigger. NULL if the global trigger value is used

G.3.11.6. The aqe_stats View

The aqe_stats view provides cumulative statistics about real-time query replanning reoptimizations. This view stores one row per each combination of the database ID, query, and execution plan. The columns of the view are shown in Table G.7.

Table G.7. `aqe_stats` Columns

Name	Type	Description
dbid	oid	ID of the database where the statement is executed
sql_hash	bigint	Internal query ID
planid	bigint	ID of the query execution plan
query	text	Internal representation of the query
last_updated	timestamp with time zone	Timestamp of the last statistics update
exec_num	bigint	Number of query executions
min_attempts	integer	Minimum number of times the query was reoptimized
max_attempts	integer	Maximum number of times the query was reoptimized
total_attempts	integer	Total number of times the query was reoptimized
reason_repeated_plan	bigint	Number of times real-time query replanning was disabled because a repeated execution plan was generated
reason_no_data	bigint	Number of times real-time query replanning was disabled because no new information was gathered during execution
reason_max_reruns	bigint	Number of times real-time query replanning was disabled because the maximum number of reruns was reached
reason_external	bigint	Number of times real-time query replanning was disabled by an extension, such as pgpro_multiplan
reruns_forced	bigint	Total number of reoptimizations caused by the manual trigger
reruns_time	bigint	Total number of reoptimizations caused by the query execution time trigger
reruns_underestimation	bigint	Total number of reoptimizations caused by the processed number of node tuples trigger
reruns_memory	bigint	Total number of reoptimizations caused by the backend memory trigger
min_planning_time	double precision	Minimum time spent planning, in milliseconds
max_planning_time	double precision	Maximum time spent planning, in milliseconds

Name	Type	Description
mean_planning_time	double precision	Mean time spent planning, in milliseconds
stddev_planning_time	double precision	Population standard deviation of time spent planning, in milliseconds
min_exec_time	double precision	Minimum time spent on query execution, in milliseconds
max_exec_time	double precision	Maximum time spent on query execution, in milliseconds
mean_exec_time	double precision	Mean time spent on query execution, in milliseconds
stddev_exec_time	double precision	Population standard deviation of time spent on query execution, in milliseconds

G.3.12. Functions

Only superuser can call the functions listed below.

`pgpro_multiplan_register_query(`*`query_string`* `text) returns record`
`pgpro_multiplan_register_query(`*`query_string`* `text, VARIADIC regtype[]) returns record`

Saves the query described in the *`query_string`* in the local cache and returns the unique pair of `sql_hash` and `const_hash`.

`pgpro_multiplan_unregister_query() returns bool`

Removes the query that was registered but not frozen from the local cache. Returns true if there are no errors.

`pgpro_multiplan_freeze(`*`plan_type`* `text) returns bool`

Freezes the last used plan for the statement. The allowed values of the `plan_type` optional argument are `serialized`, `hintset`, and `template`. The `serialized` value means that the query plan based on the serialized representation is used. With `hintset`, pgpro_multiplan uses the query plan based on the set of hints, which is formed at the stage of registered query execution. With `template`, pgpro_multiplan creates a template plan, which can be applied to the queries with table names matching the regular expressions in the pgpro_multiplan.wildcards configuration parameter. The content of `pgpro_multiplan.wildcards` is frozen along with the query for `template` plans. If the `plan_type` argument is omitted, the `serialized` query plan is used by default. Returns true if there are no errors.

`pgpro_multiplan_unfreeze(`*`sql_hash`* `bigint,` *`const_hash`* `bigint) returns bool`

Removes the plan only from the storage and keeps the query registered in the local cache. Returns true if there are no errors.

`pgpro_multiplan_remove(`*`sql_hash`* `bigint,` *`const_hash`* `bigint) returns bool`

Removes the frozen statement with the specified `sql_hash` and `const_hash`. Operates as `pgpro_multiplan_unfreeze` and `pgpro_multiplan_unregister_query` called sequentially. Returns true if there are no errors.

`pgpro_multiplan_reset(`*`dbid`* `oid) returns bigint`

Removes all records in the pgpro_multiplan storage for the specified database. Omit *`dbid`* to remove the data collected by pgpro_multiplan for the current database. Set *`dbid`* to NULL to reset data for all databases.

`pgpro_multiplan_reload_frozen_plancache() returns bool`

Drops all frozen plans and reloads them from the storage. It also drops statements that have been registered but not frozen.

`pgpro_multiplan_fs_counter() returns table`

Returns `plan_hash` of the frozen plan, the number of times each frozen statement was used, and the ID of the database where the statement was registered and used. If the frozen plan changed, the statistics of frozen statements usage is reset and recalculated using the new `plan_hash`.

`pgpro_multiplan_registered_query(`*`sql_hash`* `bigint,` *`const_hash`* `bigint) returns table`

Returns the registered query with the specified `sql_hash` and `const_hash` even if it is not frozen, for debugging purposes only. This works if the query is registered in the current backend or frozen in the current database.

`pgpro_multiplan_captured_approve(`*`dbid`* `oid,` *`sql_hash`* `bigint,` *`plan_hash`* `bigint) returns bool`

Moves the captured query to the permanent pgpro_multiplan storage. Returns true if the query has been moved successfully.

`pgpro_multiplan_set_plan_type(`*`sql_hash`* `bigint,` *`const_hash`* `bigint,` *`plan_type`* `text) returns bool`

Sets the type of the query plan for the frozen statement. The allowed values of the `plan_type` argument are `serialized` and `hintset`. To be able to use the query plan of the `hintset` type, the pg_hint_plan module must be loaded. Returns true if the plan type has been changed successfully.

`pgpro_multiplan_hintset_update(`*`sql_hash`* `bigint,` *`const_hash`* `bigint,` *`hintset`* `text) returns bool`

Allows to change the generated hint set with the set of custom hints. Custom hint-set string should not be enclosed in the special form of comment, as in pg_hint_plan, i.e. it should not start with `/*+` and end with `*/`. Returns `true` if the hint-set plan was changed successfully.

`pgpro_multiplan_captured_clean() returns bigint`

Removes all records from the pgpro_multiplan_captured_queries view. The function returns the number of removed records.

`get_sql_hash(`*`query_string`* `text) returns bigint`

Returns the internal ID (`sql_hash`) for the specified query.

`set_aqe_trigger(`*`sql_hash`* `bigint,` *`trigger_name`* `text,` *`trigger_val`* `int) returns bool`
`set_aqe_trigger(`*`sql_hash`* `bigint,` *`trigger_name`* `text,` *`trigger_val`* `double precision) returns bool`

Sets or resets the individual value of the replanning trigger for the specified query. The individual trigger value overrides the global trigger value specified in the configuration parameter. The allowed values of the *`trigger_name`* argument are `execution_time`, `memory`, or `underestimation_rate`. For `execution_time` and `memory` triggers, specify integer values. For `underestimation_rate`, you can define double precision values. To reset the individual trigger value, pass `NULL` or negative value less than -1.

`aqe_triggers_reset(`*`dbid`* `oid) returns bigint`

Removes all records from the `aqe_triggers` view for the specified database. To clean the `aqe_triggers` view for the current database, omit *`dbid`*. To remove records from this view for all databases, set *`dbid`* to `NULL`. Returns the number of removed records.

`aqe_stats_reset(dbid oid) returns bigint`

Removes all records from the `aqe_stats` view for the specified database. To clean the `aqe_stats` view for the current database, omit *`dbid`*. To remove records from this view for all databases, set *`dbid`* to `NULL`. Returns the number of removed records.

`pgpro_multiplan_restore(query_string text, hintstr texttext, paramtypes regtype[], plan_type text) returns record`

Restores the frozen plan for the specified query into the current database.

This function has the following arguments:

- *`query_string`*: The query with `$n` parameters (same as in `PREPARE statement_name AS`) for which to restore the frozen plan based on a set of hints.
- *`hintstr`*: A set of hints supported by the pg_hint_plan extension. If this argument is set to `NULL` or empty string, the standard plan will be used.
- *`parameter_type`*: An array with parameter types used in the query. If this argument is set to `NULL`, parameter types should be determined automatically.
- *`plan_type`*: The plan type. Allowed values are `serialized` and `hintset`. The `template` plan is not supported.

The function returns the unique pair of `sql_hash` and `const_hash` if the plan was restored successfully. Otherwise, it returns `NULL`.

G.3.13. Configuration Parameters

`pgpro_multiplan.enable` (`boolean`)

Enables pgpro_multiplan to use frozen plans. The default value is `off`. Only superusers can change this setting.

`pgpro_multiplan.fs_ctr_max` (`integer`)

Sets the maximum number of frozen statements returned by the `pgpro_multiplan_fs_counter()` function. The default value is 5000. This parameter can only be set at server start.

`pgpro_multiplan.max_items` (`integer`)

Sets the maximum number of entries pgpro_multiplan can operate with. The default value is 100. This parameter can only be set at server start.

`pgpro_multiplan.auto_tracking` (`boolean`)

Enables pgpro_multiplan to normalize and register queries executed using the `EXPLAIN` command automatically. The default value is `off`. Only superusers can change this setting.

`pgpro_multiplan.max_local_cache_size` (`integer`)

Sets the maximum size of local cache, in kB. The default value is zero, which means no limit. Only superusers can change this setting.

`pgpro_multiplan.wal_rw` (`boolean`)

Enables physical replication of pgpro_multiplan data. When set to `off` on the primary, no data is transferred from it to a standby. When set to `off` on a standby, any data transferred from the primary is ignored. The default value is `off`.This parameter can only be set at server start.

`pgpro_multiplan.auto_capturing` (`boolean`)

Enables the automatic query capture in pgpro_multiplan. Setting this configuration parameter to `on` allows you to see the queries with constants in the text form as well as parameterized queries in the pgpro_multiplan_captured_queries view. Also, all plans for each query are shown. Information

about executed queries is stored until the server restart. The default value is `off`. Only superusers can change this setting.

`pgpro_multiplan.max_captured_items` (`integer`)

Sets the maximum number of queries pgpro_multiplan can capture. The default value is 1000. This parameter can only be set at server start.

`pgpro_multiplan.sandbox` (`boolean`)

Enables reserving a separate area in shared memory to be used by a primary or standby node, which allows testing and analyzing queries with the existing data set without affecting the node operation. If set to `on` on the standby, pgpro_multiplan freezes plans only on this node and stores them in the "sandbox", an alternative plan storage. If enabled on the primary, the extension uses the separate shared memory area that is not replicated to the standby. Changing the parameter value resets the pgpro_multiplan cache. The default value is `off`. Only superusers can change this setting.

`pgpro_multiplan.wildcards` (`string`)

A comma-separated list of `POSIX` regular expressions that serves as a template for checking table names contained in a query. Wildcards used for table name mapping are stored in the plans frozen as the `template` plans. The default value is `.*` that matches anything. Regular expressions are applied from left to right. For example, in `^t[[:digit:]]$,^t.*,.*` the first regular expression checked is `^t[[:digit:]]$`, the next is `^t.*`, and the last is `.*`.

`pgpro_multiplan.aqe_plans_auto_approve` (`boolean`)

Enables pgpro_multiplan to add plans produced by real-time query replanning to the list of allowed plans automatically. The default value is `off`. Only superusers can change this setting. Ensure that real-time query replanning is enabled using the replan_enable configuration parameter.

`pgpro_multiplan.aqe_max_items` (`integer`)

Sets the maximum number of replanning trigger values that can be stored in the `aqe_triggers` view. The default value is 100. This parameter can only be set at server start.

`pgpro_multiplan.aqe_collect_stats` (`integer`)

Enables pgpro_multiplan to collect real-time query replanning statistics for all statements considered feasible for reoptimization. These statistics are stored in shared memory until a server shutdown and can be accessed using the `aqe_stats` view. The statistics are not replicated. For this feature to work, query ID computation should be enabled using the compute_query_id configuration parameter. The default value is `off`. Only superusers can change this setting.

`pgpro_multiplan.aqe_max_stats` (`integer`)

Sets the maximum number of real-time query replanning statistics that can be stored in the `aqe_stats` view. Further statistics will be discarded. The default value is 5000. This parameter can only be set at server start.

G.4. pgpro_pwr — workload reports

The pgpro_pwr module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's Statistics Collector views and the pgpro_stats or pg_stat_statements extension.

> **Note**
>
> Although pgpro_pwr can work with the pg_stat_statements extension, it is recommended that you use the pgpro_stats extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of pgpro_stats is assumed unless otherwise noted.

If you cannot use pgpro_stats for an observed database, but the *pg_stat_kcache* extension is available, pgpro_pwr can process pg_stat_kcache data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

pgpro_pwr can obtain summary wait statistics from the pg_wait_sampling extension. When pg_wait_sampling is in use, pgpro_pwr will reset the wait sampling profile on every sample.

pgpro_pwr is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

pgpro_pwr provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

pgpro_pwr allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see pgpro_stats for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see Section G.6.7.1). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

pgpro_pwr installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the primary server. To benefit from it, make sure that all server names and connection strings are specified and that the pgpro_pwr server can connect to all databases on all servers.

G.4.1. pgpro_pwr Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

  > **Note**
  >
  > Among the rest, pgpro_pwr tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to take samples and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for generating reports based on data from the historical repository.
- *Administrative functions* allow you to create and manage servers and baselines.

G.4.2. Prerequisites

The prerequisites assume that pgpro_pwr, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

G.4.2.1. For the pgpro_pwr Database

The pgpro_pwr extension depends on PL/pgSQL and the dblink extension.

G.4.2.2. For the Target Server

The target server must allow connections to all databases from the server where pgpro_pwr is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for pgpro_pwr since the functionality of the pgpro_stats or pg_stat_statements extensions will be provided through this database. Note, however, that pgpro_pwr will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, pgpro_stats must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:
  - `pgpro_stats.max`

    Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.
  - `pgpro_stats.track`

    Avoid changing the default value of '`top`' (note that the value of '`all`' will affect the accuracy of `%Total` fields for statements-related sections of a report).
- Set the parameters of the Postgres Pro's Statistics Collector as follows:

```
track_activities = on
track_counts = on
track_io_timing = on
track_wal_io_timing = on   # Since PostgreSQL 14
track_functions = all/pl
```

G.4.3. Installation and Setup

pgpro_pwr is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-pwr-ent-16` (for the detailed installation instructions, see Chapter 17).

> **Note**
>
> pgpro_pwr creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of pgpro_pwr with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

G.4.3.1. Simple Setup

Use this setup procedure when pgpro_pwr is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the pgpro_pwr installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.4.3.2. Complex Setup

Use this setup procedure when you intend to use pgpro_pwr for tracking workload on one or more servers and need to follow the principle of least privilege.

G.4.3.2.1. In the Target Server Database

Create a user for pgpro_pwr on the target server:

```
CREATE USER pwr_collector PASSWORD 'collector_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that `pg_hba.conf` permits such a connection from the pgpro_pwr database host. Also, grant `pwr_collector` with membership in the `pg_read_all_stats` role and the `EXECUTE` privilege on the following functions:

```
GRANT pg_read_all_stats TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_totals_reset(text,bigint) TO pwr_collector;
```

Also ensure the `SELECT` privilege on the `pgpro_stats_archiver` view:

```
GRANT SELECT ON pgpro_stats_archiver TO pwr_collector;
```

G.4.3.2.2. In the pgpro_pwr Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the pgpro_pwr installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the `USAGE` privilege on the schema where the dblink extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using `pwr_user` account:

```
\c - pwr_user
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for pgpro_pwr. For example:

```
SELECT profile.create_server('target_server_name','host=192.168.1.100 dbname=postgres
 port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

> **Note**
>
> Connection strings are stored in a pgpro_pwr table in clear-text form. Make sure no other database users can access tables of the pgpro_pwr extension.

G.4.3.3. Setting Up pgpro_pwr Roles

Up to three roles can be distinguished when pgpro_pwr is in operation:

- The *pgpro_pwr owner* role is the owner of the pgpro_pwr extension.
- The *collecting role* is used by pgpro_pwr to connect to databases and collect statistics.
- The *reporting role* is used to generate reports.

If all the actions with pgpro_pwr are performed by the superuser role `postgres`, you can skip most of the setup explained below.

G.4.3.3.1. The pgpro_pwr Owner

This role can be used to perform all actions related to pgpro_pwr. This role will have access to server connection strings, which may contain passwords. You should use this role to call the `take_sample()` function. The dblink extension is needed for this user.

Consider an example assuming each extension in its own schema:

```
\c postgres postgres
CREATE SCHEMA dblink;
CREATE EXTENSION dblink SCHEMA dblink;
CREATE USER pwr_usr with password 'pwr_pwd';
GRANT USAGE ON SCHEMA dblink TO pwr_usr;
```

```
CREATE SCHEMA profile AUTHORIZATION pwr_usr;
\c postgres pwr_usr
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.4.3.3.2. The Collecting Role

This role should be used by pgpro_pwr to connect to databases and collect statistics. Unprivileged users cannot open connections using dblink without a password, so you need to provide the password in the connection string for each server. This role should have access to all supported statistics extensions. It should also be able to perform a reset of statistics extensions.

Consider an example. If you use pgpro_stats to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgps;
CREATE EXTENSION pgpro_stats SCHEMA pgps;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgps TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgps.pgpro_stats_statements_reset TO pwr_collector;
```

If you use pg_stat_statements to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgss;
CREATE SCHEMA pgsk;
CREATE SCHEMA pgws;
CREATE EXTENSION pg_stat_statements SCHEMA pgss;
CREATE EXTENSION pg_stat_kcache SCHEMA pgsk;
CREATE EXTENSION pg_wait_sampling SCHEMA pgws;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgss TO pwr_collector;
GRANT USAGE ON SCHEMA pgsk TO pwr_collector;
GRANT USAGE ON SCHEMA pgws TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgss.pg_stat_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgsk.pg_stat_kcache_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgws.pg_wait_sampling_reset_profile TO pwr_collector;
```

Now you should set up a connection string pointing to the database with statistics extensions installed:

```
 \c postgres pwr_usr
 SELECT profile.set_server_connstr('local','dbname=postgres port=5432 host=localhost
 user=pwr_collector password=collector_pwd');
```

Password authentication must be configured in the `pg_hba.conf` file for the `pwr_collector` user.

Obviously, the collecting role should be properly configured on all servers observed by pgpro_pwr.

Now you should be able to call `take_sample()` using the `pwr_usr` role:

```
\c postgres pwr_usr
SELECT * FROM take_sample();
```

And now it's time to configure the scheduler (in our example, the `crontab` command of the `postgres` user):

```
*/30 * * * *   psql -U pwr_usr -d postgres -c 'SELECT profile.take_sample()' > /dev/
null 2>&1
```

Note that you can use the Postgres Pro password file to store passwords.

G.4.3.3.3. The Reporting Role

Any user can build a pgpro_pwr report. The minimal privileges needed to generate pgpro_pwr reports are granted to the `public` role. However a full report, with query texts, is only available to the member

of the pg_read_all_stats role. Anyway, the reporting role cannot access server connection strings, so it cannot get the passwords of servers.

G.4.3.4. Setting Extension Parameters

In postgresql.conf, you can define the following pgpro_pwr parameters:

pgpro_pwr.max (integer)

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample.

The default value is 20.

pgpro_pwr.max_sample_age (integer)

Retention time of the sample, in days. Samples aged pgpro_pwr.max_sample_age days and older are automatically deleted on the next take_sample() call.

The default value is 7 days.

pgpro_pwr.max_query_length (integer)

Maximum query length allowed in reports. All queries in a report will be truncated to pgpro_pwr.max_query_length characters.

The default value is 20 000 characters.

pgpro_pwr.track_sample_timings (boolean)

Enables collecting detailed timing statistics of pgpro_pwr's own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the v_sample_timings view.

The default value is off.

pgpro_pwr.statements_reset (boolean)

Controls the pgpro_stats/pg_stat_statements statistics reset during taking a sample. Allows you not to reset the statistics during taking a sample due to new techniques employed. When disabled, pgpro_pwr will track statement evictions using the value of the calls field. However this method does not completly prevent statistics loss. pg_stat_statements v1.11 and pgpro_stats v1.8 contain time tracking abilities that can reduce the possible data loss. When this setting is disabled, you can temporarily enable it in a session if you want to sometimes perform a reset of pgpro_stats/pg_stat_statements.

The default value is on.

pgpro_pwr.relsize_collect_mode (text)

Defines the mode of collecting relation sizes. Possible values:

- off — collection of relation sizes is based on pg_class. Although the relation sizes collected this way are rough, their collection consumes almost no resources.
- on — accurate relation sizes are collected for each sample using the pg_relation_size() function, which requires a lock on the table and is pretty resource intensive.
- schedule — accurate relation sizes are collected in the size-collection window, defined for each server.

The default value is off.

G.4.4. Managing Servers

Once installed, pgpro_pwr creates one enabled local server for the current cluster. If a server is *enabled*, pgpro_pwr includes it in sampling when no server is explicitly specified (see take_sample() for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

G.4.4.1. Server Management Functions

Use the following pgpro_pwr functions for server management:

`create_server(`*`server`* `name, `*`connstr`* `text, `*`enabled`* `boolean DEFAULT TRUE, `*`max_sample_age`* `integer DEFAULT NULL `*`description`* `text DEFAULT NULL)`

Creates a server definition.

Arguments:

- *`server`* — server name. Must be unique.
- *`connstr`* — connection string. Must contain all the necessary settings to connect from pgpro_pwr server to the target server database.
- *`enabled`* — set to include the server in sampling by the `take_sample()` function without arguments.
- *`max_sample_age`* — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- *`description`* — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres
 port=5432');
```

`drop_server(`*`server`* `name)`

Drops a server and all its samples.

`set_server_description(`*`server`* `name `*`description`* `text)`

Sets a new server description.

`set_server_subsampling(`*`server`* `name, `*`subsample_enabled`* `boolean, `*`min_query_duration`* `interval, `*`min_xact_duration`* `interval, `*`min_xact_age`* `integer, `*`min_idle_xact_dur`* `interval hour to second)`

Defines subsample settings for a server.

Arguments:

- *`server`* — server name.
- *`subsample_enabled`* — defines whether subsampling is enabled for the server, that is, whether `take_subsample()` function should actually take a subsample.
- *`min_query_duration`* — the query duration threshold.
- *`min_xact_duration`* — the transaction duration threshold.
- *`min_xact_age`* — the transaction age threshold.
- *`min_idle_xact_dur_age`* — the idle transaction threshold.

`enable_server(`*`server`* `name)`

Includes a server in sampling by the `take_sample()` function without arguments.

`disable_server(`*`server`* `name)`

Excludes a server from sampling by the `take_sample()` function without arguments.

`rename_server(`*`server`* `name, `*`new_name`* `name)`

Renames a server.

`set_server_max_sample_age(server name, max_sample_age integer)`

Sets the retention period for a server (in days). To reset the server retention, set the value of *max_sample_age* to `NULL`.

`set_server_db_exclude(server name, exclude_db name[])`

Excludes a list of databases on a server from sampling. Use when pgpro_pwr is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

`set_server_connstr(server name, server_connstr text)`

Sets the connection string for a server.

`set_server_setting(server name, setting text, value jsonb)`

Fine-tunes settings of the server statistics collection. `collect*` settings control which statistics should be collected, and *value* for these settings accepts bollean values, with the default equal to `true`. Available settings:

- `collect_pg_stat_statement` — collect statement statistics using pg_stat_statements and pg_stat_kcache extensions.
- `collect_pg_wait_sampling` — collect wait event statistics using the pg_wait_sampling extension.
- `collect_objects` — collect all the schema object statistics, that is, tables, indexes, and functions, from `pg_stat_*` views.
- `collect_relations` — collect statistics on tables and indexes from `pg_stat_*` views.
- `collect_functions` — collect statistics on user functions from the `pg_stat_user_functions` view.
- `collect_vacuum_stats` — collect the extended vacuum statistics.

`show_server_settings(server name)`

Returns the statistics collection settings for the specified server.

`show_servers()`

Displays the list of configured servers.

G.4.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

G.4.5.1. Sampling Functions

The following pgpro_pwr functions relate to sampling:

`take_sample()`
`take_sample(server name [, skip_sizes boolean])`

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be `OK` if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns `0` on success.

Arguments:

- *server* — server name.
- *skip_sizes* — if omitted or set to null, the size-collection policy applies; if `false`, relation sizes are collected; if `true`, the collection of relation sizes is skipped.

`take_sample_subset([sets_cnt integer, current_set integer])`

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- *sets_cnt* — number of subsets to divide all enabled servers into.
- *current_set* — number of the subset to collect samples for. Takes values from 0 through *sets_cnt* - 1. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, pgpro_pwr treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

`show_samples([server name,] [days integer])`

Returns a table with information on server samples (`local` server is assumed if *server* is omitted) for the last *days* days (all existing samples are assumed if omitted). This table has the following columns:

- `sample` — sample identifier.
- `sample_time` — time when this sample was taken.
- `dbstats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- `clustats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- `archstats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

G.4.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * *   psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns `OK` for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
  server   |                                    result
  |   elapsed
-----------
+-------------------------------------------------------------------------------
+-------------
 ok_node   | OK
  | 00:00:00.48
 fail_node | could not establish connection
 +| 00:00:00
```

```
            | SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
 +|
            | PL/pgSQL function take_sample(integer) line 69 at PERFORM
 +|
            | PL/pgSQL function take_sample_subset(integer,integer) line 27 at
 assignment+|
            | SQL function "take_sample" statement 1
 +|
            | FATAL:  database "postgresno" does not exist
  |
(2 rows)
```

G.4.5.3. Sample Retention Policy

You can define sample retention at the following levels:

1. *Global*

   The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

2. *Server*

   Specifying the *`max_sample_age`* parameter while creating a server or calling the `set_server_max_sample_age(`*`server`*`,`*`max_sample_age`*`)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

3. *Baseline*

   A baseline created overrides all the other retention periods for included samples.

G.4.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. pgpro_pwr allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

`set_server_size_sampling(`*`server`* `name,` *`window_start`* `time with time zone DEFAULT NULL,` *`window_duration`* `interval hour to second DEFAULT NULL,` *`sample_interval`* `interval day to minute DEFAULT NULL,` *`collect_mode`* `text DEFAULT NULL)`

Defines the size-collection policy for a server.

Arguments:

- *`server`* — server name.
- *`window_start`* — start time of the size-collection window.
- *`window_duration`* — duration of the size-collection window.
- *`sample_interval`* — minimum time gap between two samples with relation sizes collected.
- *`collect_mode`* — when set to `off`, which is the default for new installations, relation sizes are collected from `pg_class`, when set to `on`, relation sizes are collected using the `pg_relation_size()` function, when set to `schedule`, pgpro_pwr collects the relation size in the size-collection window. This parameter overrides the relsize_collect_mode extension parameter. Up-

grading from a previous version sets the value of this parameter to `on` or `schedule`, so the previous behavior does not change.

> **Note**
>
> When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the *`with_growth`* parameter of report generation functions; this makes the growth data more accurate.
>
> Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8 hour',
 'schedule');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
 server_name | window_start | window_end  | window_duration | sample_interval |
 limited_collection
-------------+--------------+-------------+-----------------+-----------------
+--------------------
 local       | 23:00:00+03  | 01:00:00+03 | 02:00:00        | 08:00:00        | t
```

G.4.7. Managing Subsamples

Some performance-related data available in Postgres Pro is not cumulative. For example, the most often used data about session states is available through the pg_stat_activity view and can only be obtained with frequent samples. However, the `take_sample()` function is heavy and can take considerable amount of time. So it is not suitable for collecting session state data.

The *subsample* feature provides a new fast `take_subsample()` function. It can be used to collect relatively fast changing data. Every subsample is bound to the next regular sample and is deleted by the retention policy together with it.

The subsample feature can be used to capture the most interesting session states:

- Long running queries
- Long transactions
- Aged transactions, that is, those that hold a snapshot behind a lot of other transactions
- Transactions being in an idle state for a long time

G.4.7.1. Subsampling Functions

The following pgpro_pwr functions relate to subsampling:

`take_subsample()`
`take_subsample(`*`server`* `name)`

If the parameter is omitted, the function takes a subsample on each *enabled* server with subsampling enabled (see set_server_subsampling for details). Server subsamples are taken sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the subsample. Can be `OK` if the subsample was taken successfully or contain the error text in case of exception.
- `elapsed` — time elapsed while the subsample was taken.

This tabular return format makes it easy to control subsample creation using an SQL query.

If called with the parameter, the function takes a subsample for the specified server. Use when you need different subsampling frequencies on servers or if you want to take an explicit subsample on a specific server.

Arguments:

- *server* — server name.

> **Note**
>
> Trying to take a subsample during taking a sample fails.

`take_subsample_subset([sets_cnt integer], [current_set integer])`

Takes subsamples for a subset of enabled servers with subsampling enabled. Although subsamples should be fast enough for serial processing, subsamples can be taken in parallel, like regular samples. This function returns the same type as `take_subsample()`. If both parameters are omitted, the function behaves like the `take_subsample()` function.

Arguments:

- *sets_cnt* — number of server subsets.
- *current_set* — the subset to process. Takes values from 0 through *sets_cnt* - 1. For the specified subset, subsamples are collected as usual, server by server.

G.4.7.2. Configuring the Subsample Feature

The following settings affect the subsample behaviour:

- `pgpro_pwr.subsample_enabled` — defines whether the `take_subsample()` function should actually take a subsample.
- `pgpro_pwr.min_query_duration` — the long running query threshold.
- `pgpro_pwr.min_xact_duration` — the long transaction threshold.
- `pgpro_pwr.min_xact_age` — the transaction age threshold.
- `pgpro_pwr.min_idle_xact_dur_age` — the idle transaction threshold.

The subsample behavior can be defined at the server level using the set_server_subsampling function.

The last observed session state is saved in the repository when either of the following threshold-related events happens:

- During query execution, the difference between `now()` and the `query_start` exceeds the `pgpro_pwr.min_query_duration` threshold.
- During a transaction, the difference between `now()` and the `xact_start` exceeds the `pgpro_pwr.min_xact_duration` threshold.
- During a transaction, the `age(backend_xmin)` exceeds the `pgpro_pwr.min_xact_age` threshold.
- During a transaction in a state `idle in transaction` or `idle in transaction (aborted)`, the difference between `now()` and the `state_change` exceeds the `pgpro_pwr.min_idle_xact_duration` threshold.

See Chapter 28 for details of the mentioned fields. Every subsample can hold at most `pg_profile.topn` entries for every threshold type.

G.4.7.3. Scheduling Subsamples

Subsamples are fast enough to take them quite often. However usually you do not need more than 2-4 subsamples per minute. Obviously the subsample frequency depends on the shortest used duration of a threshold setting.

Cron only allows one call per minute, so some effort is needed to schedule more frequent subsamples. For example, the `\watch` psql command can be used:

```
echo "select take_subsample(); \watch 15" | psql &> /dev/null
```

The psql call can be wrapped in the systemd service like this:

```
Description=pg_profile subsampling unit
[Unit]

[Service]
Type=simple
ExecStart=/bin/sh -c 'echo "select take_subsample(); \\watch 15" | /path/to/psql -qo /
dev/null'
User=postgres
Group=postgres

[Install]
WantedBy=multi-user.target
```

G.4.8. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

G.4.8.1. Baseline Management Functions

Use the following pgpro_pwr functions for baseline management:

`create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [, days integer])`
`create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days integer])`

Creates a baseline.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *baseline* — baseline name. Must be unique for a server.
- *start_id* — identifier of the first sample in the baseline.
- *end_id* — identifier of the last sample in the baseline.
- *time_range* — time interval for the baseline. The baseline will include all samples for the minimal interval that covers *time_range*.
- *days* — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

`drop_baseline([server name,] baseline varchar(25))`

Drops a baseline. For the meaning and usage details of function arguments, see create_baseline. Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

`keep_baseline([server name,] baseline varchar(25) [, days integer])`

Changes the retention of a baseline. For the meaning and usage details of function arguments, see create_baseline. Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

`show_baselines([server name])`

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. `local` sever is assumed if the *`server`* parameter is omitted.

G.4.9. Data Export and Import

Collected samples can be exported from one instance of the pgpro_pwr extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

G.4.9.1. Data Export

The export_data function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of psql to obtain a single `csv` file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

G.4.9.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the import_data function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

> **Note**
>
> If server data is imported for the first time, your local pgpro_pwr servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you can specify the server name prefix for import operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported severs. Also keep in mind that pgpro_pwr sets servers being imported to the *disabled* state for `take_sample()` to bypass them.

G.4.9.3. Export and Import Functions

Use these functions to export or import data:

`export_data([server name, [min_sample_id integer,] [max_sample_id integer,]] [, obfuscate_queries boolean])`

Exports collected data.

Arguments:

- *`server`* — server name. All configured servers are assumed if omitted.
- *`min_sample_id`*, *`max_sample_id`* — sample identifiers to bound the export (inclusive). If *`min_sample_id`* is omitted or set to null, all samples until *`max_sample_id`* sample are exported; if *`max_sample_id`* is omitted or set to null, all samples since *`min_sample_id`* sample are exported.
- *`obfuscate_queries`* — if `true`, query texts are exported as `MD5` hash.

`import_data(data regclass [, server_name_prefix text])`

Imports previously exported data. Returns the number of actually loaded rows in pgpro_pwr tables.

Arguments:

- *data* is the name of the table containing import data.
- *server_name_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

G.4.10. Report Generation Functions

pgpro_pwr reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

G.4.10.1. Regular Reports

Use these functions to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [,
with_growth boolean [, db_exclude name[]]]])
get_report([server name,] time_range tstzrange [, description text [, with_growth boolean
[, db_exclude name[]]]])
get_report([server name,] baseline varchar(25) [, description text [, with_growth boolean
[, db_exclude name[]]]])
```

Generates a regular report defined by the arguments.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start_id* — identifier of the interval starting sample.
- *end_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time_range* — time range.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

```
get_report_latest([server name,])
get_report_latest([server name [, db_exclude name[]]])
```

Generates a regular report for two latest samples.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.4.10.2. Differential Reports

Use this function to generate differential reports:

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,
end2_id integer [, description text [, with_growth boolean [, db_exclude name[]]]])
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description
text [, with_growth boolean [, db_exclude name[]]]])
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description
text [, with_growth boolean [, db_exclude name[]]]])
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description
text [, with_growth boolean[, db_exclude name[]]]])
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description
text [, with_growth boolean[, db_exclude name[]]]])
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)
[, description text [, with_growth boolean[, db_exclude name[]]]])
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer
[, description text [, with_growth boolean[, db_exclude name[]]]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start1_id*, *end1_id* — identifiers of the starting and ending samples for the first interval.
- *start2_id*, *end2_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time_range1* — time range for the first interval.
- *time_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.4.10.3. Report Generation Example

Generate a report for the `local` server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report(tstzrange('2020-05-13 11:51:35+03','2020-05-13
 11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o
 report_last_day.html
```

G.4.11. pgpro_pwr Report Sections

Each pgpro_pwr report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the `pgpro_pwr.max` parameter.

Almost every item in the report can be accentuated by a single mouse click. The accentuated item will be instantly highlighted in all report sections, making it easy to find. The attributes identifying the item will appear in the bottom-right corner of the page. For example, if you click on a database name in the "Database statistics" report table, you can notice a small table with the database attributes in the bottom-right corner of the page.

When you scroll down the report, its table of contents will be available on the right side of the page. It can be hidden with a single mouse click on the "content" tag.

A substring-based filter is also available that helps limit the report contents to particular objects based on a substring. Specifically, substring-based filtering is applied to query texts.

G.4.11.1. Server statistics

Tables in this section of a pgpro_pwr report are described below.

The report table "Database statistics" provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. Table G.8 lists columns of this report table.

Table G.8. Database statistics

Column	Description	Field/Calculation
`Database`	Database name	`datname`
`Commits`	Number of committed transactions	`xact_commit`
`Rollbacks`	Number of rolled back transactions	`xact_rollback`
`Deadlocks`	Number of deadlocks detected	`deadlocks`
`Checksum Failures`	Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	`checksum_failures`
`Checksums Last`	Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	`checksum_last_failure`
`Hit%`	Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched	
`Read`	Number of disk blocks read in this database	`blks_read`
`Hit`	Number of times disk blocks were found already in the buffer cache	`blks_hit`
`Ret`	Number of returned tuples	`tup_returned`
`Fet`	Number of fetched tuples	`tup_fetched`
`Ins`	Number of inserted tuples	`tup_inserted`
`Upd`	Number of updated tuples	`tup_updated`
`Del`	Number of deleted tuples	`tup_deleted`

Column	Description	Field/Calculation
Temp Size	Total amount of data written to temporary files by queries in this database	temp_bytes
Temp Files	Number of temporary files created by queries in this database	temp_files
Size	Database size at the time of the last sample in the report interval	pg_database_size()
Growth	Database growth during the report interval	pg_database_size() increment between interval bounds

The report table “Cluster I/O statistics” provides I/O statistics by object types, backend types and contexts. This table is based on the pg_stat_io view of the Cumulative Statistics System, available since Postgres Pro 16. Table G.9 lists columns of this report table. Times are provided in seconds.

Table G.9. Cluster I/O statistics

Column	Description
Object	Target object of an I/O operation
Backend	Type of the backend that performed an I/O operation
Context	The context of an I/O operation
Reads Count	Number of read operations
Reads Bytes	Amount of data read
Reads Time	Time spent in read operations
Writes Count	Number of write operations
Writes Bytes	Amount of data written
Writes Time	Time spent in write operations
Writebacks Count	Number of blocks which the process requested the kernel write out to permanent storage
Writebacks Bytes	Amount of data requested for write out to permanent storage
Writebacks Time	Time spent in writeback operations, including the time spent queueing write-out requests and, potentially, the time spent to write out the dirty data
Extends Count	Number of relation extend operations
Extends Bytes	Amount of space used by extend operations
Extends Time	Time spent in extend operations
Hits	The number of times a desired block was found in a shared buffer
Evictions	Number of times a block has been written out from a shared or local buffer in order to make it available for another use
Reuses	The number of times an existing buffer in a size-limited ring buffer outside of shared buffers was reused as part of an I/O operation in the bulkread, bulkwrite, or vacuum contexts
Fsyncs Count	Number of fsync calls. These are only tracked in context normal.

Column	Description
Fsyncs Time	Time spent in fsync operations

The report table “Cluster SLRU statistics” provides access statistics on SLRU (simple least-recently-used) caches. This table is based on the pg_stat_slru view of the Cumulative Statistics System. Table G.10 lists columns of this report table. Times are provided in seconds.

Table G.10. Cluster SLRU statistics

Column	Description	Field/Calculation
Name	Name of the SLRU	name
Zeroed	Number of blocks zeroed during initializations	blks_zeroed
Hits	Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLRU, not the operating system's file system cache)	blks_hit
Reads	Number of disk blocks read for this SLRU	blks_read
%Hit	Number of disk block hits for this SLRU as the percentage of Reads + Hits	blks_hit *100/blks_read + blks_hit
Writes	Number of disk blocks written for this SLRU	blks_written
Checked	Number of blocks checked for existence for this SLRU	blks_exists
Flushes	Number of flushes of dirty data for this SLRU	flushes
Truncates	Number of truncates for this SLRU	truncates

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the pg_stat_database view of the Statistics Collector. Table G.11 lists columns of this report table. Times are provided in seconds.

Table G.11. Session statistics by database

Column	Description	Field/Calculation
Database	Database name	
Timing Total	Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included)	session_time
Timing Active	Time spent executing SQL statements in this database during the report interval (this corresponds to the states active and fastpath function call in pg_stat_activity)	active_time

Column	Description	Field/Calculation
Timing Idle(T)	Time spent idling while in a transaction in this database during the report interval (this corresponds to the states idle in transaction and idle in transaction (aborted) in pg_stat_activity)	idle_in_transaction_time
Sessions Established	Total number of sessions established to this database during the report interval	sessions
Sessions Abandoned	Number of database sessions to this database that were terminated because connection to the client was lost during the report interval	sessions_abandoned
Sessions Fatal	Number of database sessions to this database that were terminated by fatal errors during the report interval	sessions_fatal
Sessions Killed	Number of database sessions to this database that were terminated by operator intervention during the report interval	sessions_killed

In Postgres Pro Enterprise databases of versions that include pgpro_stats version starting with 1.4, workload statistics of vacuum processes are available. The “Database vacuum statistics” report table provides per-database aggregated total vacuum statistics based on the pgpro_stats_vacuum_tables view. Table G.12 lists columns of this report table. Times are provided in seconds.

Table G.12. Database vacuum statistics

Column	Description	Field/Calculation
Database	Database name	
Blocks fetched	Total number of database blocks fetched by vacuum operations	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster	Blocks fetched * 100 / Cluster fetched
Blocks read	Total number of database blocks read by vacuum operations	total_blks_read
%Total	Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster	Blocks read * 100 / Cluster read
VM Frozen	Total number of blocks marked all-frozen in the visibility map	pages_frozen
VM Visible	Total number of blocks marked all-visible in the visibility map	pages_all_visible
Tuples deleted	Total number of dead tuples vacuum operations deleted from tables of this database	tuples_deleted

Column	Description	Field/Calculation
Tuples left	Total number of dead tuples vacuum operations left in tables of this database due to their visibility in transactions	dead_tuples
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of tuples deleted from tables of this database in all dead tuples to be deleted from tables of this database.	tuples_deleted * 100 / (tuples_deleted + dead_tuples)
WAL size	Total amount of WAL bytes generated by vacuum operations performed on tables of this database	wal_bytes
Read I/O time	Time spent reading database blocks by vacuum operations performed on tables of this database	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on tables of this database	blk_write_time
%Total	Vacuum I/O time spent as the percentage of whole cluster I/O time	
Total vacuum time	Total time of vacuuming tables of this database	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on tables of this database	delay_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Interrupts	Number of times vacuum operations performed on tables of this database were interrupted on any errors	interrupts

If the pgpro_stats extension supporting invalidation statistics was available during the report interval, the "Invalidation messages by database" report table provides per-database aggregated total invalidation message statistics. Table G.13 lists columns of this report table.

Table G.13. Invalidation messages by database

Column	Description	Field/Calculation
Database	Database name	
Invalidation messages sent	Total number of invalidation messages sent by backends in this database. Statistics are provided for corresponding message	Fields of pgpro_stats_totals.inval_msgs

Column	Description	Field/Calculation
	types of pgpro_stats_inval_msgs	
Cache resets	Total number of shared cache resets	pgpro_stats_totals .cache_resets

If the pgpro_stats extension was available during the report interval, the “Statement statistics by database” report table provides per-database aggregated total statistics for the pgpro_stats_statements view data. Table G.14 lists columns of this report table. Times are provided in seconds.

Table G.14. Statement statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Read Time	Time spent reading blocks by all statements in the database	Sum of blk_read_time
Write Time	Time spent writing blocks by all statements in the database	Sum of blk_write_time
Trg Time	Time spent executing trigger functions by all statements in the database	
Shared Fetched	Total number of shared blocks fetched by all statements in the database	Sum of (shared_blks_read + shared_blks_hit)
Local Fetched	Total number of local blocks fetched by all statements in the database	Sum of (local_blks_read + local_blks_hit)
Shared Dirtied	Total number of shared blocks dirtied by all statements in the database	Sum of shared_blks_dirtied
Local Dirtied	Total number of local blocks dirtied by all statements in the database	Sum of local_blks_dirtied
Read Temp	Total number of temp blocks read by all statements in the database	Sum of temp_blks_read
Write Temp	Total number of temp blocks written by all statements in the database	Sum of temp_blks_written
Read Local	Total number of local blocks read by all statements in the database	Sum of local_blks_read
Write Local	Total number of local blocks written by all statements in the database	Sum of local_blks_written

Column	Description	Field/Calculation
Statements	Total number of captured statements	
WAL Size	Total amount of WAL generated by all statements in the database	Sum of wal_bytes

The “Statement average min/max timings” report table contains per-database aggregated min/max timing statistics from the one of pgpro_stats or pg_stat_statements extensions that was available during the report interval, with the precedence of pgpro_stats. This report is sensitive to the fastest and slowest planning and execution of every statement in a cluster. That is, you can see execution and planning stability in your database. Table G.15 lists columns of this report table.

Table G.15. Statement average min/max timings

Column	Description
Database	Database name
Min average planning time (ms)	The average value of min_plan_time for all statements and all samples included in the report
Max average planning time (ms)	The average value of max_plan_time for all statements and all samples included in the report
Delta% of average planning times	Difference between the mean max_plan_time and mean min_plan_time as the percentage of the mean min_plan_time . The less this difference, the more stable query planning in your database is.
Min average execution time (ms)	The average value of min_exec_time for all statements and all samples included in the report
Max average execution time (ms)	The average value of max_exec_time for all statements and all samples included in the report
Delta% of average execution times	Difference between the mean max_exec_time and mean min_exec_time as the percentage of the mean min_exec_time . The less this difference, the more stable query execution in your database is.
Statements	Total count of captured statements

If the JIT-related statistics was avaliable in the statement statistics extension during the report interval, the “JIT statistics by database” report table provides per-database aggregated total statistics of JIT executions. Table G.16 lists columns of this report table. Times are provided in seconds.

Table G.16. JIT statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Generation count	Total number of functions JIT-compiled by the statements	Sum of jit_functions

Column	Description	Field/Calculation
Generation time	Total time spent by the statements on generating JIT code	Sum of jit_generation_time
Inlining count	Number of times functions have been inlined	Sum of jit_inlining_count
Inlining time	Total time spent by statements on inlining functions	Sum of jit_inlining_time
Optimization count	Number of times statements have been optimized	Sum of jit_optimization_count
Optimization time	Total time spent by statements on optimizing	Sum of jit_optimization_time
Emission count	Number of times code has been emitted	Sum of jit_emission_count
Emission time	Total time spent by statements on emitting code	Sum of jit_emission_time
Deform count	Number of tuple deform functions JIT-compiled by the statement of the database	
Deform time	Total time spent by the statements of the database on JIT-compiling the tuple deform functions	

The report table “Cluster statistics” provides data from the pg_stat_bgwriter view. Table G.17 lists rows of this report table. Times are provided in seconds.

Table G.17. Cluster statistics

Row	Description	Field/Calculation
Scheduled checkpoints	Number of scheduled checkpoints that have been performed	checkpoints_timed
Requested checkpoints	Number of requested checkpoints that have been performed	checkpoints_req
Checkpoint write time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are written to disk	checkpoint_write_time
Checkpoint sync time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk	checkpoint_sync_time
Checkpoint buffers written	Number of buffers written during checkpoints	buffers_checkpoint
Background buffers written	Number of buffers written by the background writer	buffers_clean
Backend buffers written	Number of buffers written directly by a backend. Will not be shown since Postgres Pro 17.	buffers_backend
Backend fsync count	Number of times a backend had to execute its own fsync call (normally the background writer handles those even when the	buffers_backend_fsync

Row	Description	Field/Calculation
	backend does its own write). Will not be shown since Postgres Pro 17.	
Bgwriter interrupts (too many buffers)	Number of times the background writer stopped a cleaning scan because it had written too many buffers	maxwritten_clean
Number of buffers allocated	Total number of buffers allocated	buffers_alloc
WAL generated	Total amount of WAL generated	pg_current_wal_lsn() value increment
Start LSN	Log sequence number at the start of a report interval	pg_current_wal_lsn() at the first sample of a report
End LSN	Log sequence number at the end of a report interval	pg_current_wal_lsn() at the last sample of a report
WAL generated by vacuum	Total amount of WAL generated by vacuum	Based on the wal_bytes field of the pgpro_stats_vacuum_databases view.
WAL segments archived	Total number of archived WAL segments	Based on pg_stat_archiver.archived_count
WAL segments archive failed	Total number of WAL segment archiver failures	Based on pg_stat_archiver.failed_count .
Archiver performance	Average archiver process performance per second	Based on the active_time field of the pgpro_stats_archiver view.
Archive command performance	Average archive_command performance per second	Based on the archive_command_time field of the pgpro_stats_archiver view.

Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the pg_stat_wal view of the Statistics Collector. Table G.18 lists columns of this report table. Times are provided in seconds.

Table G.18. WAL statistics

Row	Description	Field/Calculation
WAL generated	Total amount of WAL generated during the report interval	wal_bytes
WAL per second	Average amount of WAL generated per second during the report interval	wal_bytes / report_duration
WAL records	Total number of WAL records generated during the report interval	wal_records
WAL FPI	Total number of WAL full page images generated during the report interval	wal_fpi
WAL buffers full	Number of times WAL data was written to disk because WAL buffers became full during the report interval	wal_buffers_full

Row	Description	Field/Calculation
WAL writes	Number of times WAL buffers were written out to disk via XLogWrite request during the report interval	wal_write
WAL writes per second	Average number of times WAL buffers were written out to disk via XLogWrite request per second during the report interval	wal_write / report_duration
WAL sync	Number of times WAL files were synced to disk via issue_xlog_fsync request during the report interval (if fsync is on and wal_sync_method is either fdatasync, fsync or fsync_writethrough , otherwise zero). See Section 30.5 for more information about the internal WAL function issue_xlog_fsync .	wal_sync
WAL syncs per second	Average number of times WAL files were synced to disk via issue_xlog_fsync request per second during the report interval	wal_sync / report_duration
WAL write time	Total amount of time spent writing WAL buffers to disk via XLogWrite request during the report interval (if track_wal_io_timing is enabled, otherwise zero; for more details, see Section 19.9). This includes the sync time when wal_sync_method is either open_datasync or open_sync .	wal_write_time
WAL write duty	WAL write time as the percentage of the report interval duration	wal_write_time * 100 / report_duration
WAL sync time	Total amount of time spent syncing WAL files to disk via issue_xlog_fsync request during the report interval (if track_wal_io_timing is enabled, fsync is on, and wal_sync_method is either fdatasync, fsync or fsync_writethrough , otherwise zero).	wal_sync_time
WAL sync duty	WAL sync time as the percentage of the report interval duration	wal_sync_time * 100 / report_duration

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. Table G.19 lists columns of this report table.

Table G.19. Tablespace statistics

Column	Description	Field/Calculation
`Tablespace`	Tablespace name	`pg_tablespace .spcname`
`Path`	Tablespace path	`pg_tablespace_location()`
`Size`	Tablespace size at the time of the last sample in the report interval	`pg_tablespace_size()`
`Growth`	Tablespace growth during the report interval	`pg_tablespace_size()` increment between interval bounds

If the pgpro_stats extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. Table G.20 lists columns of this report table.

Table G.20. Wait statistics by database

Column	Description
`Database`	Database name
`Wait event type`	Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database.
`Waited (s)`	Time spent waiting in events of `Wait event type`, in seconds
`%Total`	Percentage of wait time spent in the database events of `Wait event type` in all wait time for the cluster

If the pgpro_stats extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. Table G.21 lists columns of this report table.

Table G.21. Top wait events

Column	Description
`Database`	Database name
`Wait event type`	The type of event for which the backends were waiting
`Wait event`	Wait event name for which the backends were waiting
`Waited`	Total wait time spent in `Wait event` of the database, in seconds
`%Total`	Percentage of wait time spent in `Wait event` of the database in all wait time in the cluster

G.4.11.2. Load distribution

This section of a pgpro_pwr report is based on the `pgpro_stats_totals` view of the pgpro_stats extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage.

The report tables “Load distribution among heavily loaded databases”, “Load distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. Table G.22 lists rows of these report tables.

Table G.22. Load distribution

Row	Description	Calculation
Total time (sec.)	Total time spent in the planning and execution of statements	total_plan_time + total_exec_time
Executed count	Number of queries executed	queries_executed
I/O time (sec.)	Total time the statements spent reading or writing blocks (if track_io_timing is enabled, otherwise zero)	blk_read_time + blk_write_time
Blocks fetched	Total number of shared block cache hits and shared blocks read by the statements	shared_blks_hit + shared_blks_read
Shared blocks read	Total number of shared blocks read by the statements	shared_blks_read
Shared blocks dirtied	Total number of shared blocks dirtied by the statements	shared_blks_dirtied
Shared blocks written	Total number of shared blocks written by the statements	shared_blks_written
WAL generated	Total amount of WAL generated by the statements	wal_bytes
Temp and Local blocks written	Total number of temporary and local blocks written by the statements	temp_blks_written + local_blks_written
Temp and Local blocks read	Total number of temp and local blocks read by the statements	temp_blks_read + local_blks_read
Invalidation messages sent	Total number of all invalidation messages sent by backends in this database	(pgpro_stats_totals.inval_msgs).all
Cache resets	Total number of shared cache resets	pgpro_stats_totals.cache_resets

G.4.11.3. Session states observed by subsamples

This section of a pgpro_pwr report provides information about session states captured by subsamples during the report interval.

Tables of this report section are described below.

The report subsection “Chart with session state” visualizes session states captured by subsamples. It is the timeline chart showing captured session states in backends and transactions. Every state contains a popup with session state attributes. Click on a state to see this state in the table of session states.

The report table “Session state statistics by database” shows the aggregated data on session states. Only session states captured in subsamples are counted. Table G.23 lists columns of this report table.

Table G.23. Session state statistics by database

Column	Description
Database	Database name

Column	Description
Summary Active	Overall time of active states captured in subsamples
Summary Idle in xact	Overall time of idle in transaction states captured in subsamples
Summary Idle in xact (A)	Overall time of idle in transaction (aborted) states captured in subsamples
Maximal Active	Time of the longest active state captured in subsamples
Maximal Idle in xact	Time of the longest idle in transaction state captured in subsamples
Maximal Idle in xact (A)	Time of the longest idle in transaction (aborted) state captured in subsamples
Maximal xact age	Maximal transaction age detected in subsamples

The report table “Top 'idle in transaction' session states by duration” shows top pgpro_pwr.topn longest idle in transaction states that were last observed in the pg_stat_activity view for each session. Table G.24 lists columns of this report table.

Table G.24. Top 'idle in transaction' session states by duration

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	usename
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

The report table “Top 'active' session states by duration” shows top pgpro_pwr.topn longest active states that were last observed in the pg_stat_activity view for each session. Table G.25 lists columns of this report table.

Table G.25. Top 'active' session states by duration

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	usename
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

The report table “Top states by transaction age” shows top session states by transaction age that were last observed in the pg_stat_activity view for each session. Table G.26 lists columns of this report table.

Table G.26. Top states by transaction age

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	usename
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
Xact duration	Transaction duration	clock_timestamp() - xact_start
Age	Transaction age	age(backend_xmin)
State	Session state at the maximum age detected	
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

The report table “Top states by transaction duration” shows top longest session states that were last observed in the pg_stat_activity view for each session. Table G.27 lists columns of this report table.

Table G.27. Top states by transaction duration

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	usename
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
Xact duration	Transaction duration	clock_timestamp() - xact_start
Age	Transaction age	age(backend_xmin)
State	Session state at the maximum age detected	
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

G.4.11.4. SQL query statistics

This section of a pgpro_pwr report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of pgpro_stats and pg_stat_statements extensions that was available during the report interval, with the precedence of pgpro_stats. Each statement can be highlighted in all SQL-related sections with a single mouse click on it. This click will also show a query text preview just under the query statistics row. The query text preview can be hidden with a second click on a query.

Tables of this report section are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of total_plan_time and total_exec_time fields of the pgpro_stats_statements or pg_stat_statements view. Table G.28 lists columns of this report table. Times are provided in seconds.

Table G.28. Top SQL by elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
%Total	Percentage of elapsed time of this statement plan in the total elapsed time of all statements in the cluster	
Elapsed Time (s)	Total time spent in planning and execution of the statement plan	total_plan_time + total_exec_time
Plan Time (s)	Total time spent in planning of the statement	total_plan_time
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by planning time” shows top statements by the value of the total_plan_time field of the pgpro_stats_statements or pg_stat_statements view. Table G.29 lists columns of this report table.

Table G.29. Top SQL by planning time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan elapsed(s)	Total time spent in planning of the statement, in seconds	total_plan_time
%Elapsed	Percentage of total_plan_time in the sum of total_plan_time and total_exec_time of this statement plan	
Mean plan time	Mean time spent planning the statement, in milliseconds	mean_plan_time
Min plan time	Minimum time spent planning the statement, in milliseconds	min_plan_time
Max plan time	Maximum time spent planning the statement, in milliseconds	max_plan_time
StdErr plan time	Population standard deviation of time spent planning the statement, in milliseconds	stddev_plan_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by execution time” shows top statements by the value of the total_time field of the pgpro_stats_statements or pg_stat_statements view. Table G.30 lists columns of this report table.

Table G.30. Top SQL by execution time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Exec (s)	Total time spent executing the statement plan, in seconds	total_exec_time
%Elapsed	Percentage of total_exec_time of this statement plan in this statement elapsed time	
%Total	Percentage of total_exec_time of this statement plan in the total elapsed time of all statements in the cluster	
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Read I/O time (s)	Total time spent in reading pages while executing the statement plan, in seconds	blk_read_time
Write I/O time (s)	Total time spent in writing pages while executing the statement plan, in seconds	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean execution time	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min execution time	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max execution time	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr execution time	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_exec_time
Executions	Number of executions of this statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table "Top SQL by mean execution time" shows top `pgpro_pwr.topn` statements by the value of the `mean_time` or `mean_exec_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. Table G.31 lists columns of this report table.

Table G.31. Top SQL by mean execution time

Column	Description	Field/Calculation
`Query ID`	Hex representation of `queryid`. The hash of the query ID, database ID and user ID is in square brackets. The `(N)` mark will appear here for nested statements (such as statements invoked within top-level statements).	
`Database`	Database name for the statement	Derived from `dbid`
`User`	Name of the user executing the statement	Derived from `userid`
`Mean execution time (ms)`	Mean time spent executing the statement, in milliseconds	`mean_exec_time`
`Min execution time (ms)`	Minimum time spent executing the statement, in milliseconds	`min_exec_time`
`Max execution time (ms)`	Maximum time spent executing the statement, in milliseconds	`max_exec_time`
`StdErr execution time`	Population standard deviation of time spent executing the statement, in milliseconds	`stddev_exec_time (ms)`
`Exec (s)`	Time spent executing this statement, in seconds	`total_exec_time`
`%Elapsed`	Execution time of this statement as the percentage of the statement elapsed time	
`%Total`	Execution time of this statement as the percentage of the total elapsed time of all statements in the cluster	
`JIT time (s)`	Total time spent by JIT executing this statement, in seconds	`jit_generation_time` + `jit_inlining_time` + `jit_optimization_time` + `jit_emission_time`
`Read I/O time (s)`	Time spent reading blocks, in seconds	`blk_read_time`
`Write I/O time (s)`	Time spent writing blocks, in seconds	`blk_write_time`
`Rows`	Number of rows retrieved or affected by the statement	`rows`
`Executions`	Number of times this statement was executed	`calls`
`%Cvr`	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table "Top SQL by executions" shows top statements by the value of the `calls` field of the `pgpro_stats_statements` or `pg_stat_statements` view. Table G.32 lists columns of this report table.

Table G.32. Top SQL by executions

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Executions	Number of executions of the statement plan	calls
%Total	Percentage of calls of this statement plan in the total calls of all statements in the cluster	
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean (ms)	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min (ms)	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max (ms)	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr (ms)	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_time
Elapsed(s)	Total time spent executing the statement plan, in seconds	total_exec_time
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by I/O wait time” shows top statements by read and write time, i.e., sum of values of blk_read_time and blk_write_time fields of the pgpro_stats_statements or pg_stat_statements view. Table G.33 lists columns of this report table. Times are provided in seconds.

Table G.33. Top SQL by I/O wait time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements	

Column	Description	Field/Calculation
	(such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
IO(s)	Total time spent in reading and writing while executing this statement plan, i.e., I/O time	blk_read_time + blk_write_time
R(s)	Total time spent in reading while executing this statement plan	blk_read_time
W(s)	Total time spent in writing while executing this statement plan	blk_write_time
%Total	Percentage of I/O time of this statement plan in the total I/O time of all statements in the cluster	
Shr Reads	Total number of shared blocks read while executing the statement plan	shared_blks_read
Loc Reads	Total number of local blocks read while executing the statement plan	local_blks_read
Tmp Reads	Total number of temp blocks read while executing the statement plan	temp_blks_read
Shr Writes	Total number of shared blocks written while executing the statement plan	shared_blks_written
Loc Writes	Total number of local blocks written while executing the statement plan	local_blks_written
Tmp Writes	Total number of temp blocks written while executing the statement plan	temp_blks_written
Elapsed(s)	Total time spent in execution of the statement plan	total_plan_time + total_exec_time
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks fetched” shows top statements by the number of read and hit blocks, which helps to detect the most data-intensive statements. Table G.34 lists columns of this report table.

Table G.34. Top SQL by shared blocks fetched

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Blks fetched	Number of blocks retrieved while executing the statement plan	shared_blks_hit + shared_blks_read
%Total	Percentage of blocks fetched while executing the statement plan in all blocks fetched for all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks read” shows top statements by the number of shared reads, which helps to detect the most read-intensive statements. Table G.35 lists columns of this report table.

Table G.35. Top SQL by shared blocks read

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid

Column	Description	Field/Calculation
User	Name of the user executing the statement	Derived from userid
Reads	Number of shared blocks read while executing this statement plan	shared_blks_read
%Total	Percentage of shared reads for this statement plan in all shared reads of all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks dirtied” shows top statements by the number of shared dirtied buffers, which helps to detect statements that do most data changes in the cluster. Table G.36 lists columns of this report table.

Table G.36. Top SQL by shared blocks dirtied

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
%Total	Percentage of dirtied shared buffers for this statement plan in all dirtied shared buffers of all statements in the cluster	

Column	Description	Field/Calculation
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks written” shows top statements by the number of blocks written. Table G.37 lists columns of this report table.

Table G.37. Top SQL by shared blocks written

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Written	Number of blocks written while executing this statement plan	shared_blks_written
%Total	Percentage of blocks written by this statement plan in all written blocks in the cluster	Percentage of shared_blks_written in (pg_stat_bgwriter.buffers_checkpoint + pg_stat_bgwriter.buffers_clean + pg_stat_bgwriter.buffers_backend)
%BackendW	Percentage of blocks written by this statement plan in all blocks in the cluster written by backends	Percentage of shared_blks_written in pg_stat_bgwriter.buffers_backend

Column	Description	Field/Calculation
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by WAL size” shows top statements by the amount of WAL generated. Table G.38 lists columns of this report table.

Table G.38. Top SQL by WAL size

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
WAL FPI	Total number of WAL full page images generated by the statement plan	wal_fpi
WAL records	Total number of WAL records generated by the statement plan	wal_records
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by temp usage” shows top statements by temporary I/O, which is calculated as the sum of `temp_blks_read`, `temp_blks_written`, `local_blks_read` and `local_blks_written` fields. Table G.39 lists columns of this report table.

Table G.39. Top SQL by temp usage

Column	Description	Field/Calculation
`Query ID`	Hex representation of `queryid`. The hash of the query ID, database ID and user ID is in square brackets. The `(N)` mark will appear here for nested statements (such as statements invoked within top-level statements).	
`Plan ID`	Internal hash code, computed from the tree of the statement plan	`planid`
`Database`	Database name for the statement	Derived from `dbid`
`User`	Name of the user executing the statement	Derived from `userid`
`Local fetched`	Number of local blocks retrieved	`local_blks_hit` + `local_blks_read`
`Hits(%)`	Percentage of local blocks got from buffers in all local blocks got	
`Write Local (blk)`	Number of blocks written by this statement plan that are used in temporary tables	`local_blks_written`
`Write Local %Total`	Percentage of `local_blks_written` of this statement plan in the total of `local_blks_written` for all statements in the cluster	
`Read Local (blk)`	Number of blocks read by this statement plan that are used in temporary tables	`local_blks_read`
`Read Local %Total`	Percentage of `local_blks_read` of this statement plan in the total of `local_blks_read` for all statements in the cluster	
`Write Temp (blk)`	Number of temp blocks written by this statement plan	`temp_blks_written`
`Write Temp %Total`	Percentage of `temp_blks_written` of this statement plan in the total of `temp_blks_written` for all statements in the cluster	
`Read Temp (blk)`	Number of temp blocks read by this statement plan	`temp_blks_read`
`Read Temp %Total`	Percentage of `temp_blks_read` of this statement plan in the to-	

Column	Description	Field/Calculation
	tal of temp_blks_read for all statements in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by invalidation messages sent” shows top statements by the number of invalidation messages sent. Table G.40 lists columns of this report table.

Table G.40. Top SQL by invalidation messages sent

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	queryid
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Invalidation messages sent	Total number of invalidation messages sent by backends executing this statement. Statistics are provided for corresponding message types of pgpro_stats_inval_msgs	fields of pgpro_stats_statements.inval_msgs

G.4.11.4.1. rusage statistics

This section is included in the report only if the pgpro_stats or pg_stat_kcache extension was available during the report interval.

The report table “Top SQL by system and user time” shows top statements by the sum of user_time and system_time fields of pg_stat_kcache or of the pgpro_stats_totals view. Table G.41 lists columns of this report table.

Table G.41. Top SQL by system and user time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square	

Column	Description	Field/Calculation
	brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan User (s)	User CPU time elapsed during planning, in seconds	plan_user_time
Exec User (s)	User CPU time elapsed during execution, in seconds	exec_user_time
User %Total	Percentage of plan_user_time + exec_user_time in the total user CPU time for all statements	
Plan System (s)	System CPU time elapsed during planning, in seconds	plan_system_time
Exec System (s)	System CPU time elapsed during execution, in seconds	exec_system_time
System %Total	Percentage of plan_system_time + exec_system_time in the total system CPU time for all statements	

The report table “Top SQL by reads/writes done by filesystem layer” shows top statements by the sum of reads and writes fields of pg_stat_kcache. Table G.42 lists columns of this report table.

Table G.42. Top SQL by reads/writes done by filesystem layer

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan Read Bytes	Bytes read during planning	plan_reads
Exec Read Bytes	Bytes read during execution	exec_reads
Read Bytes %Total	Percentage of plan_reads + exec_reads in the total number of bytes read by the filesystem layer for all statements	

Column	Description	Field/Calculation
Plan Writes	Bytes written during planning	plan_writes
Exec Writes	Bytes written during execution	exec_writes
Write %Total	Percentage of plan_writes + exec_writes in the total number of bytes written by the filesystem layer for all statements	

G.4.11.5. SQL query wait statistics

If the pgpro_stats extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain wait event type. Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. Table G.43 lists columns of this report table. Times are provided in seconds.

Table G.43. SQL query wait statistics

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Hash of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Waited	Total wait time for all wait events of this statement plan	
%Total	Percentage of the total wait time of this statement plan in all the wait time in the cluster	
Details	Waits of this statement plan by wait types	

If the JIT-related statistics was avaliable in the statement statistics extension during the report interval, the report table “Top SQL by JIT elapsed time” shows top statements by the sum of jit_*_time fields of the pgpro_stats_statements or pg_stat_statements view. Table G.44 lists columns of this report table. Times are provided in seconds.

Table G.44. Top SQL by JIT elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
JIT Time (s)	Total time spent by JIT executing this statement plan	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Generation count	Total number of functions JIT-compiled by this statement	Sum of jit_functions
Generation time	Total time spent by this statement on generating JIT code	Sum of jit_generation_time
Inlining count	Number of times functions have been inlined	Sum of jit_inlining_count
Inlining time	Total time spent by this statement on inlining functions	Sum of jit_inlining_time
Optimization count	Number of times this statement has been optimized	Sum of jit_optimization_count
Optimization time	Total time spent by this statement on optimizing	Sum of jit_optimization_time
Emission count	Number of times code has been emitted	Sum of jit_emission_count
Emission time	Total time spent by this statement on emitting code	Sum of jit_emission_time
Deform count	Number of tuple deform functions JIT-compiled by the statement	
Deform time	Total time spent by the statement on JIT-compiling the tuple deform	
Plan Time (s)	Total time spent in planning of the statement	total_plan_time
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

G.4.11.6. Complete list of SQL texts

The “Complete list of SQL texts” section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate Query ID/Plan ID link in any statistics table to see the corresponding query/plan text. Table G.45 lists columns of this report table.

Table G.45. Complete list of SQL texts

Column	Description
ID	Hex representation of the query or plan identifier
Query/Plan Text	Text of the query or statement plan

G.4.11.7. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's Statistics Collector views. Report tables that contain data for tables and indexes provide a preview of storage parameters. You can click on a row to see storage parameters of the object right under the row.

The report table “Top tables by estimated sequentially scanned volume” shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. The data is based on the pg_stat_all_tables view. Table G.46 lists columns of this report table.

Table G.46. Top tables by estimated sequentially scanned volume

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
~SeqBytes	Estimated volume read by sequential scans	Sum of (pg_relation_size() * seq_scan)
SeqScan	Number of sequential scans performed on the table	seq_scan
IxScan	Number of index scans initiated on the table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks fetched for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the pg_statio_all_tables view. Table G.47 lists columns of this report table.

Table G.47. Top tables by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	

Column	Description	Field/Calculation
Table	Table name	
Heap Blks	Number of blocks fetched for the table's heap	heap_blks_read + heap_blks_hit
Heap Blks %Total	Percentage of blocks fetched for the table's heap in all blocks fetched in the cluster	
Ix Blks	Number of blocks fetched for table's indexes	idx_blks_read + idx_blks_hit
Ix Blks %Total	Percentage of blocks fetched for table's indexes in all blocks fetched in the cluster	
TOAST Blks	Number of blocks fetched for the table's TOAST table	toast_blks_read + toast_blks_hit
TOAST Blks %Total	Percentage of blocks fetched for the table's TOAST table in all blocks fetched in the cluster	
TOAST-Ix Blks	Number of blocks fetched for the table's TOAST index	tidx_blks_read + tidx_blks_hit
TOAST-Ix Blks %Total	Percentage of blocks fetched for the table's TOAST index in all blocks fetched in the cluster	

The report table “Top tables by blocks read” shows top database tables by the number of blocks read for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the pg_statio_all_tables view. Table G.48 lists columns of this report table.

Table G.48. Top tables by blocks read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks read for the table's heap	heap_blks_read
Heap Blks %Total	Percentage of blocks read from the table's heap in all blocks read in the cluster	
Ix Blks	Number of blocks read from table's indexes	idx_blks_read
Ix Blks %Total	Percentage of blocks read from table's indexes in all blocks read in the cluster	
TOAST Blks	Number of blocks read from the table's TOAST table	toast_blks_read
TOAST Blks %Total	Percentage of blocks read from the table's TOAST table in all blocks read in the cluster	

Column	Description	Field/Calculation
TOAST-Ix Blks	Number of blocks read from the table's TOAST index	tidx_blks_read
TOAST-Ix Blks %Total	Percentage of blocks read from the table's TOAST index in all blocks read in the cluster	
Hit(%)	Percentage of table, index, TOAST and TOAST index blocks got from buffers for this table in all blocks got for this table from either file system or buffers	

The report table “Top DML tables” shows top tables by the number of DML-affected rows, i.e., by the sum of n_tup_ins, n_tup_upd and n_tup_del (including TOAST tables). The data is based on the pg_stat_all_tables view. Table G.49 lists columns of this report table.

Table G.49. Top DML tables

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd
SeqScan	Number of sequential scans performed on the table	seq_scan
SeqFet	Number of live rows fetched by sequential scans	seq_tup_read
IxScan	Number of index scans initiated on this table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch

The report table “Top tables by updated/deleted tuples” shows top tables by tuples modified by UPDATE/DELETE operations, i.e., by the sum of n_tup_upd and n_tup_del (including TOAST tables). The data is based on the pg_stat_all_tables view. Table G.50 lists columns of this report table.

Table G.50. Top tables by updated/deleted tuples

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Upd	Number of rows updated, including HOT	n_tup_upd

Column	Description	Field/Calculation
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd
Del	Number of rows deleted	n_tup_del
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Analyze	Number of times this table was manually analyzed	analyze_count
AutoAnalyze	Number of times this table was analyzed by the autovacuum daemon	autoanalyze_count

The report table “Top tables by removed all-visible marks” shows top tables by the number of times that the all-visible mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. Table G.51 lists columns of this report table.

Table G.51. Top tables by removed all-visible marks

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Visible marks cleared	Number of times that the all-visible mark was removed from the relation visibility map	rev_all_visible_pages
All-Visible marks set	Number of times that the all-visible mark was set in the relation visibility map	pages_all_visible
All-Visible marks %Set	Percentage of the number of times that the all-visible mark was set in the number of times that it was set or removed	pages_all_visible * 100% / (rev_all_visible_pages + pages_all_visible)
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by removed all-frozen marks” shows top tables by the number of times that the all-frozen mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. Table G.52 lists columns of this report table.

Table G.52. Top tables by removed all-frozen marks

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Frozen marks cleared	Number of times that the all-frozen mark was removed from the relation visibility map	rev_all_frozen_pages
All-Frozen marks set	Number of times that the all-frozen mark was set in the relation visibility map	pages_frozen
All-Frozen marks %Set	Percentage of the number of times that the all-frozen mark was set in the number of times that it was set or removed	pages_frozen * 100% / (rev_all_frozen_pages + pages_frozen)
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by new-page updated tuples” shows top tables by the number of rows updated where the successor version goes onto a *new* heap page, leaving behind an original version with a t_ctid field that points to a different heap page. These are always non-HOT updates. Table G.53 lists columns of this report table.

Table G.53. Top tables by new-page updated tuples

Column	Description
DB	Database name for the table
Tablespace	Name of the tablespace where the table is located
Schema	Schema name for the table
Table	Table name
NP Upd	Number of rows updated to a new heap page
%Upd	Number of new-page updated rows as the percentage of all rows updated
Upd	Number of rows updated, including HOT
Upd(HOT)	Number of rows HOT updated (i.e., with no separate index update required)

The report table “Top growing tables” shows top tables by growth. The data is based on the pg_stat_all_tables view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.54 lists columns of this report table.

Table G.54. Top growing tables

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Size	Table size at the time of the last sample in the report interval	pg_table_size() - pg_relation_size(toast)
Growth	Table growth	
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

In the report table “Top indexes by blocks fetched”, blocks fetched include index blocks processed from disk (read) and from shared buffers (hit). The data is based on the pg_statio_all_indexes view. Table G.55 lists columns of this report table.

Table G.55. Top indexes by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	idx_scan
Blks	Number of blocks fetched for this index	idx_blks_read + idx_blks_hit
%Total	Percentage of blocks fetched for this index in all blocks fetched in the cluster	

The report table “Top indexes by blocks read” is also based on the pg_statio_all_indexes and pg_stat_all_indexes views. Table G.56 lists columns of this report table.

Table G.56. Top indexes by blocks read

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	

Column	Description	Field/Calculation
Scans	Number of index scans initiated on this index	idx_scan
Blk Reads	Number of disk blocks read from this index	idx_blks_read
%Total	Percentage of disk blocks read from this index in all disk blocks read in the cluster	
Hits(%)	Percentage of index blocks got from buffers in all index blocks got for this index	

The report table “Top growing indexes” shows top indexes by growth. The table uses data from the pg_stat_all_tables and pg_stat_all_indexes views. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.57 lists columns of this report table.

Table G.57. Top growing indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

The report table “Unused indexes” shows top non-scanned indexes (during the report interval) by DML operations on underlying tables that caused index support. Constraint indexes are not counted. The table uses data from the pg_stat_all_tables view. Table G.58 lists columns of this report table.

Table G.58. Unused indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	

Column	Description	Field/Calculation
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

G.4.11.8. User function statistics

Tables in this section of the report show top functions in the cluster by statistics from the pg_stat_user_functions view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table “Top trigger functions by total time” shows top trigger functions by the total time elapsed. Table G.59 lists columns of these report tables.

Table G.59. User function statistics

Column	Description	Field/Calculation
DB	Database name for the function	
Schema	Schema name for the function	
Function	Function name	
Executions	Number of times this function has been called	calls
Total Time (s)	Total time spent in this function and all other functions called by it	total_time
Self Time (s)	Total time spent in this function itself, not including other functions called by it	self_time
Mean Time (s)	Mean time of a single function execution	total_time /calls
Mean self Time (s)	Mean self time of a single function execution	self_time /calls

G.4.11.9. Vacuum-related statistics

The report table “Top tables by vacuum time spent” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by total time spent vacuuming them. The data is based on the pgpro_stats_vacuum_tables view. Table G.60 lists columns of this report table.

Table G.60. Top tables by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Total vacuum time	Total time of vacuuming this table	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this table	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this table	blk_write_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by vacuum time spent” is available if pgpro_stats can provide extended vacuum statistics. This table shows top indexes by total time spent vacuuming them. The data is based on the pgpro_stats_vacuum_indexes view. Table G.61 lists columns of this report table.

Table G.61. Top indexes by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
Total vacuum time	Total time of vacuuming this index	total_time

Column	Description	Field/Calculation
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this index	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this index	blk_write_time
User CPU time	User CPU time of vacuuming this index	user_time
System CPU time	System CPU time of vacuuming this index	system_time
Vacuum count	Number of times the underlying table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times the underlying table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on the underlying table	total_blks_read + total_blks_hit
Index fetched	Total number of blocks fetched from this index by vacuum operations performed on it	rel_blks_read + rel_blks_hit

The report table “Top tables by blocks vacuum fetched” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by blocks fetched vacuuming these tables. The data is based on the pgpro_stats_vacuum_tables view. Table G.62 lists columns of this report table.

Table G.62. Top tables by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read

Column	Description	Field/Calculation
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
%Rel	Total number of table blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched from this table	
Heap read	Total number of blocks read from this table by vacuum operations performed on it	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum fetched” is available if pgpro_stats can provide extended vacuum statistics. This table shows top indexes by blocks fetched vacuuming underlying tables. The data is based on the pgpro_stats_vacuum_indexes view. Table G.63 lists columns of this report table.

Table G.63. Top indexes by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this index	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations per-	

Column	Description	Field/Calculation
	formed on this index as the percentage of all blocks read in the cluster	
Idx fetched	Total number of blocks fetched from this index by vacuum operations on it	rel_blks_read + rel_blks_hit
%Idx	Total number of index blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched from this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	

The report table “Top tables by blocks vacuum read” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by blocks read vacuuming these tables. The data is based on the pgpro_stats_vacuum_indexes view. Table G.64 lists columns of this report table.

Table G.64. Top tables by blocks vacuum read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this table as the percentage of all blocks fetched by vacuum operations performed on this table	
Heap read	Total number of database blocks vacuum operations read from this table	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the per-	

Column	Description	Field/Calculation
	centage of all blocks read from this table	
%Hit	Total number of table blocks found in shared buffers by vacuum operations performed on this table as the percentage of table blocks fetched by vacuum operations performed on this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum read” is available if pgpro_stats can provide extended vacuum statistics. This table shows top indexes by blocks read vacuuming underlying tables. The data is based on the pgpro_stats_vacuum_indexes view. Table G.65 lists columns of this report table.

Table G.65. Top indexes by blocks vacuum read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this index as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this index as the percentage of all database blocks fetched by vacuum operations performed on this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	
%Hit	Total number of index blocks found in shared buffers by vacuum operations performed on this index as the percentage of index	

Column	Description	Field/Calculation
	blocks fetched by vacuum operations performed on this index	

The report table “Top tables by dead tuples vacuum left” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by the number of dead tuples left by vacuum due to their visibility in transactions. The data is based on the `pgpro_stats_vacuum_tables` view. Table G.66 lists columns of this report table.

Table G.66. Top tables by dead tuples vacuum left

Column	Description	Field/Calculation
`DB`	Database name for the table	
`Tablespace`	Name of the tablespace where the table is located	
`Schema`	Schema name for the table	
`Table`	Table name	
`Dead tuples left`	Total number of dead tuples vacuum operations left in this table due to their visibility in transactions	`dead_tuples`
`Dead tuples deleted`	Total number of dead tuples vacuum operations deleted from this table	`tuples_deleted`
`%Eff`	Vacuum efficiency in terms of deleted tuples. This is the percentage of dead tuples deleted from this table in all dead tuples to be deleted from this table.	`tuples_deleted` * 100 / (`tuples_deleted` + `dead_tuples`)
`Tuples del`	Number of rows deleted	`pg_stat_all_tables .n_tup_del`
`Tuples upd`	Number of rows updated (includes HOT updated rows)	`pg_stat_all_tables .n_tup_upd`
`Vacuum`	Number of times this table has been manually vacuumed (not counting `VACUUM FULL`)	`vacuum_count`
`Autovacuum`	Number of times this table has been vacuumed by the autovacuum daemon	`autovacuum_count`

The report table “Top tables by WAL size generated by vacuum” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by the amount of WAL generated by vacuum operations performed on them. The data is based on the `pgpro_stats_vacuum_tables` view. Table G.67 lists columns of this report table.

Table G.67. Top tables by WAL size generated by vacuum

Column	Description	Field/Calculation
`DB`	Database name for the table	
`Tablespace`	Name of the tablespace where the table is located	
`Schema`	Schema name for the table	

Column	Description	Field/Calculation
Table	Table name	
WAL size	Total amount of WAL bytes generated by vacuum operations performed on this table	wal_bytes
%Total	Total amount of WAL bytes generated by vacuum operations performed on this table as the percentage of all WAL generated in the cluster	
WAL FPI	Total number of WAL full page images generated by vacuum operations performed on this table	wal_fpi
Scanned blocks	Number of pages examined by vacuum operations performed on this table	pages_scanned
Dirtied blocks	Number of database blocks dirtied by vacuum operations performed on this table	total_blks_dirtied
Removed blocks	Number of pages removed by vacuum operations performed on this table	pages_removed
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by vacuum operations” shows top tables by the number of vacuum operations performed (vacuum_count + autovacuum_count). The data is based on the pg_stat_all_tables view. Table G.68 lists columns of this report table.

Table G.68. Top tables by vacuum operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated (includes HOT updated rows)	n_tup_upd
Del	Number of rows deleted	n_tup_del

Column	Description	Field/Calculation
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top tables by analyze operations” shows top tables by the number of analyze operations performed (analyze_count + autoanalyze_count). The data is based on the pg_stat_all_tables view. Table G.69 lists columns of this report table.

Table G.69. Top tables by analyze operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Analyze count	Number of times this table has been manually analyzed	analyze_count
Autoanalyze count	Number of times this table has been analyzed by the autovacuum daemon	autoanalyze_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the pg_stat_all_indexes view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.70 lists columns of this report table.

Table G.70. Top indexes by estimated vacuum load

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
~Vacuum bytes	Vacuum load estimation	(vacuum_count + autovacuum_count) * index_size
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

Column	Description	Field/Calculation
IX size	Average index size during the report interval	
Relsize	Average relation size during the report interval	

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the pg_stat_all_tables view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.71 lists columns of this report table.

Table G.71. Top tables by dead tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
%Dead	Percentage of dead rows in all table rows	
Last AV	Last time at which this table was vacuumed by the autovacuum daemon	last_autovacuum
Size	Table size	pg_table_size() - pg_relation_size(toast)

The report table “Top tables by modified tuples ratio” shows top tables larger than 5 MB by the ratio of modified tuples. Statistics are valid for the last sample in the report interval. The data is based on the pg_stat_all_tables view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.72 lists columns of this report table.

Table G.72. Top tables by modified tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
Mod	Estimated number of rows modified since this table was last analyzed	n_mod_since_analyze
%Mod	Percentage of modified rows in all table rows	
Last AA	Last time at which this table was analyzed by the autovacuum daemon	last_autoanalyze
Size	Table size	pg_table_size() - pg_relation_size(toast)

G.4.11.10. Cluster settings during the report interval

This section of the report contains a table with Postgres Pro GUC parameters, values of functions `version()`, `pg_postmaster_start_time()`, `pg_conf_load_time()` and the `system_identifier` field of the `pg_control_system()` function during the report interval. The data in the table is grouped under `Defined settings` and `Default settings`. Table G.73 lists columns of this report table.

Table G.73. Cluster settings during the report interval

Column	Description
`Setting`	Name of the parameter
`reset_val`	`reset_val` field of the `pg_settings` view. Settings changed during the report interval are shown in bold font.
`Unit`	Unit of the setting
`Source`	Configuration file where this setting is defined, semicolon, line number
`Notes`	Timestamp of the sample where this value was first observed

G.4.11.11. Extension versions during the report interval

This section of the report contains a table that lists installed extension versions found in databases during the report interval. `First seen` and `Last seen` columns are not shown if the extension versions have not changed during the report interval. Table G.74 lists columns of this report table.

Table G.74. Extension versions during the report interval

Column	Description
`Name`	Extension name
`DB`	Database name
`First seen`	Timestamp of the sample where this extension version appeared first
`Last seen`	Timestamp of the sample where this extension version appeared last
`Version`	Version name of the extension

G.4.12. pgpro_pwr Diagnostic Tools

pgpro_pwr provides self-diagnostic tools.

G.4.12.1. Collecting Detailed Timing Statistics for Sampling Procedures

pgpro_pwr collects detailed timing statistics of taking samples when the *`pgpro_pwr.track_sample_timings`* parameter is on. You can get the results from the `v_sample_timings` view. Table G.75 lists columns of this view.

Table G.75. `v_sample_timings` View

Column	Description
`server_name`	Name of the server
`sample_id`	Sample identifier
`sample_time`	Time when the sample was taken
`sampling_event`	Sampling stage. See Table G.76 for descriptions of sampling stages.

Column	Description
time_spent	Time spent in the event

Table G.76. sampling_event Description

Event	Description
total	Taking the sample (all stages)
connect	Making dblink connection to the server
get server environment	Getting server GUC parameters, available extensions, etc.
collect database stats	Querying the pg_stat_database view for statistics on databases
calculate database stats	Calculating differential statistics on databases since the previous sample
collect tablespace stats	Querying the pg_tablespace view for statistics on tablespaces
collect statement stats	Collecting statistics on statements using the pg_pro_stats and pg_stat_kcache extensions
query pg_stat_bgwriter	Collecting cluster statistics using the pg_stat_bgwriter view
query pg_stat_archiver	Collecting cluster statistics using the pg_stat_archiver view
collect object stats	Collecting statistics on database objects. Includes events from Table G.77.
maintain repository	Executing support routines
calculate tablespace stats	Calculating differential statistics on tablespaces
calculate object stats	Calculating differential statistics on database objects. Includes events from Table G.78.
calculate cluster stats	Calculating cluster differential statistics
calculate archiver stats	Calculating archiver differential statistics
delete obsolete samples	Deleting obsolete baselines and samples

Table G.77. Events of Collecting Statistics on Database Objects

Event	Description
db:*dbname* collect tables stats	Collecting statistics on tables for the *dbname* database
db:*dbname* collect indexes stats	Collecting statistics on indexes for the *dbname* database
db:*dbname* collect functions stats	Collecting statistics on functions for the *dbname* database

Table G.78. Events of Calculating Differences of Statistics on Database Objects

Event	Description
calculate tables stats	Calculating differential statistics on tables of all databases
calculate indexes stats	Calculating differential statistics on indexes of all databases

Event	Description
`calculate functions stats`	Calculating differential statistics on functions of all databases

G.4.13. Important Notes

When using the pgpro_pwr extension, be aware of the following:

- Postgres Pro collects execution statistics *after* the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which the execution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpointer, will update the statistics only on completion.
- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the `take_sample()` function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

G.5. pgpro_result_cache — save query results for reuse

G.5.1. Description

The pgpro_result_cache extension caches query results in shared memory using hints, improving performance for subsequent query executions. Cached results are not persisted over server restarts.

G.5.2. Installation

The pgpro_result_cache extension is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-result-cache-ent-16` (for the detailed installation instructions, see Chapter 17).

To enable pgpro_result_cache, complete the following steps:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'pgpro_result_cache'
   ```

   Note that the library names in the `shared_preload_libraries` variable must be added in the specific order. For information on compatibility of pgpro_result_cache with other extensions, see Section G.5.4.

2. Restart the database server for the changes to take effect.

   To verify that the `pgpro_result_cache` library has been installed correctly, run the following command:

   ```
   SHOW shared_preload_libraries;
   ```

3. Create the `pgpro_result_cache` extension using the following query:

   ```
   CREATE EXTENSION pgpro_result_cache;
   ```

   It is essential that the library is preloaded during server startup because pgpro_result_cache has a shared memory cache that can be initialized only during startup. The pgpro_result_cache extension should be created in each database where query caching is required.

G.5.3. Hints

G.5.3.1. The result_cache Hint

If a valid (TTL/Time To Live is not expired) cached result set exists in memory, it is returned immediately without query execution and the hit count increments. Otherwise, the query is executed and the result set is stored in shared memory with the current timestamp.

```
/*+result_cache*/ select now() from generate_series(1,5);
```

G.5.4. Compatibility with Other Extensions

The pgpro_result_cache extension employs flexible hint parsing, skipping any unrecognized tokens. All valid hints must conform to this syntax:

```
/*+ token_no_args token_no_args() token_with_args(optional, arguments()) */
```

Spaces are optional, except after `token_no_args` without parentheses. All parentheses must always be properly paired and closed.

The extension ignores non-conforming hints, eventually displaying warnings in the logs, and expects the same behavior from other extensions: they should follow the same hint syntax while disregarding unfamiliar tokens.

> **Note**
>
> pgpro_result_cache and the pg_hint_plan extension ignore each other's hints.

G.5.5. Cached Result Set Identification

A cached result set is identified by a combination of the `database_id`, `query_id`, `const_hash`, `params_hash`, and `query_string` attributes. `database_id` and `query_id` are the attributes assigned by the Postgres Pro Enterprise server.

`const_hash` represents a hash digest of all constants contained in the query. Constants with the same value but different types, for example `1` and `'1'`, will produce different hash values. `0` means there are no constants.

`params_hash` stores a hash digest of all parameter values used in the query. `0` means no parameters were defined.

G.5.6. Views

G.5.6.1. The `pgpro_result_cache_data` View

The `pgpro_result_cache_data` view shows all captured result sets. The columns of the view are shown in Table G.79.

Table G.79. `pgpro_result_cache_data` Columns

Name	Type	Description
`dbid`	`oid`	ID of the database where the query is executed
`query_id`	`bigint`	Standard query ID
`const_hash`	`bigint`	Hash of non-parameterized constants
`params_hash`	`bigint`	Hash of the parameters used to execute the query
`created`	`timestamp`	First caching timestamp
`exec_time_ms`	`real`	Query execution time in milliseconds
`hits`	`int`	Execution counter
`rows_count`	`int`	Number of rows in the cached result set

Name	Type	Description
data_size	bigint	Total size (in bytes) of the result set in cache memory
query_string	text	Query text in cache-readable format, without comments or EXPLAIN (ANALYZE) prefixes

G.5.6.2. The pgpro_result_cache_stat View

The pgpro_result_cache_stat view shows cache counters. The columns of the view are shown in Table G.80.

Table G.80. pgpro_result_cache_stat Columns

Name	Type	Description
free_kb	bigint	Available cache memory (in kilobytes), limited by pgpro_result_cache.max_memory_size (integer, kB)
entries	bigint	Current number of cached entries, including expired ones (if not vacuumed), limited by pgpro_result_cache.max_entries (integer)
hits	bigint	Number of successful cache retrievals
inserts	bigint	Number of new entries, including replacements of expired ones
evicts	bigint	Entries removed by LRU (Least Recently Used) policy due to the max_entries limit
cleanups	bigint	Additional entries purged to meet the max_memory_size limit
not_cached	bigint	Queries excluded from caching (too fast, too large, other conditions)

G.5.7. Functions

Only superusers can call the functions listed below.

pgpro_result_cache_reset() returns bool

Clears the cache and resets all result cache counters.

G.5.8. Configuration Parameters

pgpro_result_cache.enable (boolean)

Enables the pgpro_result_cache functionality. The default value is off. Only superusers can change this setting.

pgpro_result_cache.max_memory_size (integer, kB)

Sets the size of shared memory used for result set caching. The default value is 64kB. This parameter can only be set at server start.

`pgpro_result_cache.max_entries` (`integer`)

Sets the maximum number of cached result sets. The default value is `128`. This parameter can only be set at server start.

`pgpro_result_cache.max_entry_size` (`integer`, `kB`)

Sets the maximum memory consumption by a single result set. The default value is `16kB`. Only superusers can change this setting. Must not exceed `pgpro_result_cache.max_memory_size / 2`. The query text is stored in memory along with the result data, so this parameter value should be large enough to fit both. If set at runtime, it is applied only to new allocations and the cached data is not evicted automatically.

`pgpro_result_cache.ttl` (`integer`, `s`)

Sets the lifetime of a cache entry. The default value is `-1` (disabled). Only superusers can change this setting.

`pgpro_result_cache.min_exec_time` (`integer`, `ms`)

Sets the minimum execution time for a query. The default value is `-1` (disabled). A positive integer means that queries with execution time less than this value will not be stored in cache. Only superusers can change this setting.

G.5.9. Important Notes

When using the pgpro_result_cache extension, be aware of the following:

- The extension caches results of non-immutable functions, causing subsequent calls to return identical output.
- pgpro_result_cache does not track updates to cached data. It captures a result set at transaction time and maintains it until its TTL expires, even if the transaction is rolled back, not committed, or modified by another user. Subsequent queries will return the original cached data, even if the underlying data has changed.
- Cached results bypass *row-level security*. Ensure sensitive queries are excluded from caching.

G.6. pgpro_stats — a means for tracking planning and execution statistics of all SQL statements executed by a server

The `pgpro_stats` extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the pg_stat_statements module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.
- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.
- Calculating additional archiver statistics.
- Providing an interface to statistics about vacuuming databases, tables, and indexes collected by the core system.
- Tracing of application sessions.
- Creating views that emulate other extensions.

Note

When the server gets shut down, pgpro_stats saves the collected statistics to two dump files on disk in the format that depends on the number and order of columns in the `pgpro_stats_statements` and `pgpro_stats_totals` views. If this format has changed in a new pgpro_stats version, during the first server restart after upgrading the extension, the saved statistics will fail to be read with an error reported to the log:

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
 "pg_stat/pgpro_stats.stat"
```

or

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
 "pg_stat/pgpro_stats_totals.stat"
```

The contents of the files will be ignored, and respective statistics will be nullified. To learn whether the format has changed, see the Release Notes for pgpro_stats version being installed. To retain the previously collected statistics, download them as CSV files before upgrading.

The background information, along with views and types, related to calculating cache invalidation statistics is provided in a separate section Section G.6.9.

G.6.1. Limitations

- `pgpro_stats` can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- Texts and plans of some SPI queries are not normalized.
- `pgpro_stats` is incompatible with pg_stat_statements, as well as other extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. Moreover, if both `pgpro_stats` and pg_stat_statements are on the list of `shared_preload_libraries`, the database server will not start. Note also that in order to dump the final versions of the queries and plans, `pgpro_stats` should be the last on the list of `shared_preload_libraries`, but some existing extensions, such as `pg_pathman`, will not work at all unless they are the last on this list.
- `pgpro_stats` may not work correctly with third-party extensions that produce `CustomScan` and `ForeignScan` nodes.

G.6.2. Installation and Setup

`pgpro_stats` is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-stats-ent-16` (for the detailed installation instructions, see Chapter 17). Once you have `pgpro_stats` installed, complete the following steps to enable `pgpro_stats`:

1. Add `pgpro_stats` to the shared_preload_libraries parameter in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'pgpro_stats'
   ```

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.

   Once the server is reloaded, `pgpro_stats` starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using `pgpro_stats` configuration parameters.

3. To access the collected statistics, you have to create `pgpro_stats` extension:

   ```
   CREATE EXTENSION pgpro_stats;
   ```

In addition, query identifier calculation must be enabled in order for pgpro_stats to be active, which is done automatically if compute_query_id is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

G.6.3. Usage

- Collecting Statistics on Query Statements and Plans
- Monitoring Custom Metrics

G.6.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the pgpro_stats extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by pg_stat_statements, but also includes information on query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the pgpro_stats_statements view.

By default, pgpro_stats collects statistics on all the executed statements that satisfy the pgpro_stats.track and pgpro_stats.track_utility settings. If performance is a concern, you can set a sample rate for queries using the pgpro_stats.query_sample_rate parameter, and pgpro_stats will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, pgpro_stats uses time-based sampling. Wait events are sampled at the time interval specified by the pgpro_stats.profile_period parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the pgpro_stats.profile_period value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the pgpro_stats.profile_period parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the pgpro_stats.enable_profile parameter to false.

pgpro_stats_statements.plans and pgpro_stats_statements.calls aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for *:x_min* and *:x_max*:

```
select * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the pgpro_stats_statements view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query
 LIKE 'select * from test where%';
-[ RECORD
 1 ]----------------------------------------------------------------------------------------
queryid    | 1109491335754870054
query      | select * from test where x >= $1 and x <= $2
planid     | 8287793242828473388
plan       | Gather
           |   Output: i, x
           |   Workers Planned: 2
           |   ->  Parallel Seq Scan on public.test
           |         Output: i, x
           |         Filter: ((test.x >= $3) AND (test.x <= $4))
           |
wait_stats | {"IO": {"DataFileRead": 10}, "IPC": {"BgWorkerShutdown": 10}, "Total":
 {"IO": 10, "IPC": 10, "Total": 20}}
-[ RECORD
 2 ]----------------------------------------------------------------------------------------
queryid    | 1109491335754870054
```

```
query      | select * from test where x >= $1 and x <= $2
planid     | -9045072158333552619
plan       | Bitmap Heap Scan on public.test
           |   Output: i, x
           |   Recheck Cond: ((test.x >= $3) AND (test.x <= $4))
           |   ->  Bitmap Index Scan on test_x_idx
           |         Index Cond: ((test.x >= $5) AND (test.x <= $6))
           |

```

G.6.3.2. Monitoring Custom Metrics

With `pgpro_stats`, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in Section G.6.7.2. You must specify a unique numeric identifier of each metric in the parameter names.

   For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

   ```
   pgpro_stats.metric_1_name = index_bloat
   pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
   pgpro_stats.metric_1_db = 'postgres'
   pgpro_stats.metric_1_user = postgres
   pgpro_stats.metric_1_period = '60s'
   ```

2. Restart the server.

   `pgpro_stats` starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the `pgpro_stats_metrics` view:

   ```
   SELECT * FROM pgpro_stats_metrics;
   ```

   Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

3. If required, set up data export to a monitoring system of your choice.

G.6.4. Views

G.6.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table G.81.

Table G.81. `pgpro_stats_statements` Columns

Name	Type	References	Description
`userid`	`oid`	`pg_authid .oid`	OID of user who executed the statement
`dbid`	`oid`	`pg_database .oid`	OID of database in which the statement was executed
`toplevel`	`bool`		True if the query was executed as a top-level statement (always true if pgpro_stats.track is set to `top`)
`queryid`	`bigint`		Internal hash code, computed from the statement's parse tree
`planid`	`bigint`		Internal hash code, computed from the statement's plan tree
`query`	`text`		Text of a representative statement
`plan`	`text`		The text of the query plan, in the format defined by the pgpro_stats.plan_format configuration parameter
`plans`	`int8`		Number of times the statement was planned (if `pgpro_stats.track_planning` is enabled, otherwise zero)
`total_plan_time`	`float8`		Total time spent planning the statement, in milliseconds (if `pgpro_stats.track_planning` is enabled, otherwise zero).
`min_plan_time`	`float8`		Minimum time spent planning the statement, in milliseconds (if `pgpro_stats.track_planning` is enabled, otherwise zero)
`max_plan_time`	`float8`		Maximum time spent planning the statement, in milliseconds (if `pg-`

Name	Type	References	Description
			pro_stats.track_planning is enabled, otherwise zero)
mean_plan_time	float8		Mean time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
stddev_plan_time	float8		Population standard deviation of time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
plan_rusage	pgpro_stats_rusage		Resource usage statistics of the statement planning.
calls	int8		Number of times the statement was executed
total_exec_time	float8		Total time spent executing the statement, in milliseconds
min_exec_time	float8		Minimum time spent executing the statement, in milliseconds
max_exec_time	float8		Maximum time spent executing the statement, in milliseconds
mean_exec_time	float8		Mean time spent executing the statement, in milliseconds
stddev_exec_time	float8		Population standard deviation of time spent executing the statement, in milliseconds
exec_rusage	pgpro_stats_rusage		Resource usage statistics of the statement execution.
rows	int8		Total number of rows retrieved or affected by the statement
shared_blks_hit	int8		Total number of shared block cache hits by the statement
shared_blks_read	int8		Total number of shared blocks read by the statement

Name	Type	References	Description
shared_blks_dirtied	int8		Total number of shared blocks dirtied by the statement
shared_blks_written	int8		Total number of shared blocks written by the statement
local_blks_hit	int8		Total number of local block cache hits by the statement
local_blks_read	int8		Total number of local blocks read by the statement
local_blks_dirtied	int8		Total number of local blocks dirtied by the statement
local_blks_written	int8		Total number of local blocks written by the statement
temp_blks_read	int8		Total number of temp blocks read by the statement
temp_blks_written	int8		Total number of temp blocks written by the statement
shared_blk_read_time	float8		Total time the statement spent reading shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
shared_blk_write_time	float8		Total time the statement spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time	float8		Total time the statement spent reading local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
local_blk_write_time	float8		Total time the statement spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
temp_blk_read_time	float8		Total time the statement spent reading temp

Name	Type	References	Description
			blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
temp_blk_write_time	float8		Total time the statement spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8		Total number of WAL records generated by the statement
wal_fpi	int8		Total number of WAL full page images generated by the statement
wal_bytes	numeric		Total amount of WAL bytes generated by the statement
jit_functions	int8		Total number of functions JIT-compiled by the statement. In Postgres Pro versions lower than 15, contains zero.
jit_generation_time	float8		Total time spent by the statement on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8		Number of times functions used in the statement have been inlined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8		Total time spent by the statement on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8		Number of times the statement has been optimized. In Postgres Pro versions lower than 15, contains zero.

Name	Type	References	Description
jit_optimization_time	float8		Total time spent by the statement on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8		Number of times code has been emitted by the statement. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8		Total time spent by the statement on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_deform_count	int8		Total number of tuple deform functions JIT-compiled by the statement. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8		Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.
wait_stats	jsonb		A jsonb object containing statistics on wait events, for each execution of the query that uses the corresponding plan. Each statistic is provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.
inval_msgs	pgpro_stats_inval_msgs		Number of cache invalidation messages by type generated by the statement (if this is supported by the server, otherwise zero).
stats_since	timestamp with time zone		Time at which statistics gathering started for this statement
minmax_stats_since	timestamp with time zone		Time at which min/max statistics gathering started for this statement (fields min_plan_

Name	Type	References	Description
			time , max_plan_ time , min_exec_time and max_exec_time)

Take into account that like pg_stat_statements, pgpro_stats normalizes into one record those DML queries (containing SELECT, INSERT, UPDATE, DELETE and MERGE commands) that have equivalent structures according to some internal hash value. Being compared this way, two queries are normally considered equal if they are semantically equivalent up to constants included in the queries. All the other commands are, however, compared strictly as query texts. When the value of a constant in a query is ignored for comparison with other queries, this constant is replaced in the pgpro_stats output with a symbol of a parameter, such as, $k, where k is a positive integer. If a query already contains parameters, the initial value of k equals the number following the last number of a $n parameter in the original query text. If there are no parameters, the initial value of k equals 1. Note that sometimes hidden parameter symbols affect this numbering. For example, PL/pgSQL uses such hidden symbols to insert values of function local variables into queries, so a PL/pgSQL statement SELECT i + 1 INTO j will be represented as SELECT i + $2 in the normalized query text.

pgpro_stats uses a similar technique to normalize plan texts. When doing so, an attempt is made to associate numbers of constants in the plan text with the corresponding numbers of constants in the query text. If such an attempt appears unsuccessful for a certain constant in the plan text, it is assigned the number following the maximum number of a constant replaced in the query text. For example, consider the query:

```
SELECT 1::int, 'abc'::VARCHAR(3), 2::int;
```

pgpro_stats will replace numbers of constants in the query text and in the text of the corresponding plan as follows:

```
postgres=# SELECT query, plan FROM pgpro_stats_statements;
                      query                       |                              plan
--------------------------------------------------
+-----------------------------------------------
SELECT $1::int, $2::VARCHAR(3), $3::int          | Result
            +
                                                 |   Output: $1, $4, $3
            +
```

In this plan text, it appeared possible to associate constants numbered 1 and 3 from the query text, but not the constant numbered 2, and the latter was replaced with the number following the maximum number in the query text, that is, number 4.

Replacement of numbers in plan texts has an exception for version numbers of XML documents. If in the original query such a number is represented with a constant, e.g., '1.0', it is retained as is in the plan text rather than replaced with $k. If the version number of an XML document is represented with an expression, replacement of constants follows usual rules.

G.6.4.2. The pgpro_stats_totals View

The aggregate statistics gathered by the module are made available via a view named pgpro_stats_totals. This view contains one row for each distinct object (up to the maximum number of distinct objects that the module can track). The columns of the view are shown in Table G.82.

Table G.82. pgpro_stats_totals Columns

Name	Type	Description
object_type	text	Type of the object for which aggregated statistics are collected: "cluster", "database", "user", "client_addr", "application", "backend", "session"

Name	Type	Description
object_id	bigint	ID of the object: oid for databases and users, pid for backends, sid for sessions, NULL for others
object_name	text	Textual name of the object or NULL
queries_planned	int8	Number of queries planned
total_plan_time	float8	Total time spent in the planning of statements, in milliseconds
total_plan_rusage	pgpro_stats_rusage	Aggregate resource usage statistics of the statement planning
queries_executed	int8	Number of queries executed
total_exec_time	float8	Total time spent in the execution of statements, in milliseconds
total_exec_rusage	pgpro_stats_rusage	Aggregate resource usage statistics of the statement execution
rows	int8	Total number of rows retrieved or affected by the statements
shared_blks_hit	int8	Total number of shared block cache hits by the statements
shared_blks_read	int8	Total number of shared blocks read by the statements
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statements
shared_blks_written	int8	Total number of shared blocks written by the statements
local_blks_hit	int8	Total number of local block cache hits by the statements
local_blks_read	int8	Total number of local blocks read by the statements
local_blks_dirtied	int8	Total number of local blocks dirtied by the statements
local_blks_written	int8	Total number of local blocks written by the statements
temp_blks_read	int8	Total number of temp blocks read by the statements
temp_blks_written	int8	Total number of temp blocks written by the statements
shared_blk_read_time	float8	Total time the statements spent reading shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
shared_blk_write_time	float8	Total time the statements spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time	float8	Total time the statements spent reading local blocks, in milliseconds (if track_io_timing is en-

Name	Type	Description
		abled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
local_blk_write_time	float8	Total time the statements spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
temp_blk_read_time	float8	Total time the statements spent reading temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
temp_blk_write_time	float8	Total time the statements spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8	Total number of WAL records generated by the statements
wal_fpi	int8	Total number of WAL full page images generated by the statements
wal_bytes	numeric	Total amount of WAL bytes generated by the statements
jit_functions	int8	Total number of functions JIT-compiled by the statements. In Postgres Pro versions lower than 15, contains zero.
jit_generation_time	float8	Total time spent by the statements on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8	Number of times functions used in the statements have been inlined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8	Total time spent by the statements on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8	Number of times the statements have been optimized. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_time	float8	Total time spent by the statements on optimizing, in millisec-

Name	Type	Description
		onds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8	Number of times code has been emitted by the statements. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8	Total time spent by the statements on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_deform_count	int8	Total number of tuple deform functions JIT-compiled by the statements. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8	Total time spent by the statements on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.
wait_stats	jsonb	A jsonb object containing statistics on wait events for each execution of the queries. Each statistic is provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.
inval_msgs	pgpro_stats_inval_msgs	Number of cache invalidation messages by type generated by the statements (if this is supported by the server, otherwise zero).
cache_resets	int4	Number of shared cache resets (only for cluster, databases and backends). Gets incremented for a backend when it receives a full cache reset message.
stats_since	timestamp with time zone	Time at which statistics gathering started for the statements

G.6.4.3. The pgpro_stats_info View

The statistics of the pgpro_stats module itself are tracked and made available via a view named pgpro_stats_info. This view contains only a single row. The columns of the view are shown in Table G.83.

Table G.83. pgpro_stats_info Columns

Name	Type	Description
dealloc	bigint	Total number of times pgpro_stats_statements entries about the least-executed statements were deallocated because

Name	Type	Description
		more distinct statements than pgpro_stats.max were observed
stats_reset	timestamp with time zone	Time at which all statistics in the pgpro_stats_statements view were last reset

G.6.4.4. The pgpro_stats_metrics View

The metrics gathered by pgpro_stats are displayed in the pgpro_stats_metrics view. The table below describes the columns of the view.

Table G.84. pgpro_stats_metrics Columns

Name	Type	Description
metric_number	int4	A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.
metric_name	text	The name of the metric defined by the pgpro_stats.metric_*N*_name parameter
db_name	text	The name of the database for which a particular metric was collected
ts	timestamptz	The time when the metric value got calculated
value	jsonb	The result of the query used for metric measurement. It is serialized in jsonb as an array of objects received via to_jsonb(*resulting_row*). If an error occurs, a single object is returned that contains code, message, detail, and hint fields.

G.6.4.5. The pgpro_stats_archiver View

The pgpro_stats_archiver view will contain one row showing data about the archiver process of the cluster.

Table G.85. pgpro_stats_archiver Columns

Column	Type	Description
archived_count	bigint	Number of WAL files that have been successfully archived
last_archived_wal	text	Name of the last WAL file successfully archived
last_archived_time	timestamp with time zone	Time of the last successful archive operation
failed_count	bigint	Number of failed attempts for archiving WAL files
last_failed_wal	text	Name of the WAL file of the last failed archival operation

Column	Type	Description
last_failed_time	timestamp with time zone	Time of the last failed archival operation
active_time	int8	Overall time that the archiver process was active
archive_command_time	int8	Overall execution time of the archive command
stats_reset	timestamp with time zone	Time at which these statistics were last reset

G.6.4.6. The pgpro_stats_vacuum_database View

> **Important**
>
> Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view pg_stats_vacuum_database (see System Views for details).

The pgpro_stats_vacuum_database view will contain one row for each database in the current cluster, showing statistics about vacuuming that database. These statistics are collected by the core system as explained in Section 28.2. The table below describes the columns of the view.

Table G.86. pgpro_stats_vacuum_database Columns

Column	Type	Description
dbid	oid	OID of a database
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this database
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this database
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this database
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this database
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this database
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this database
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this database
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)

Column	Type	Description
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this database, in milliseconds (see Section 19.4.4 for details)
system_time	float8	System CPU time of vacuuming this database, in milliseconds
user_time	float8	User CPU time of vacuuming this database, in milliseconds
total_time	float8	Total time of vacuuming this database, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this database were interrupted on any errors

G.6.4.7. The pgpro_stats_vacuum_tables View

> **Important**
>
> Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view pg_stats_vacuum_tables (see System Views for details).

The pgpro_stats_vacuum_tables view will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table. These statistics are collected by the core system as explained in Section 28.2. The table below describes the columns of the view.

Table G.87. pgpro_stats_vacuum_tables Columns

Column	Type	Description
relid	oid	OID of a table
schema	name	Name of the schema this table is in
relname	name	Name of this table
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this table
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this table
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this table
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this table

Column	Type	Description
rel_blks_read	int8	Number of blocks vacuum operations read from this table
rel_blks_hit	int8	Number of times blocks of this table were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_scanned	int8	Number of pages examined by vacuum operations performed on this table
pages_removed	int8	Number of pages removed from the physical storage by vacuum operations performed on this table
pages_frozen	int8	Number of times vacuum operations marked pages of this table as all-frozen in the visibility map
pages_all_visible	int8	Number of times vacuum operations marked pages of this table as all-visible in the visibility map
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this table
tuples_frozen	int8	Number of tuples of this table that vacuum operations marked as frozen
dead_tuples	int8	Number of dead tuples vacuum operations left in this table due to their visibility in transactions
index_vacuum_count	int8	Number of times indexes on this table were vacuumed
rev_all_frozen_pages	int8	Number of times the all-frozen mark in the visibility map was removed for pages of this table
rev_all_visible_pages	int8	Number of times the all-visible mark in the visibility map was removed for pages of this table
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this table
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this table
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this table

Column	Type	Description
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table, in milliseconds (see Section 19.4.4 for details)
system_time	float8	System CPU time of vacuuming this table, in milliseconds
user_time	float8	User CPU time of vacuuming this table, in milliseconds
total_time	float8	Total time of vacuuming this table, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this table were interrupted on any errors

Columns total_*, wal_* and blk_* include data on vacuuming indexes on this table, while columns system_time and user_time only include data on vacuuming the heap.

G.6.4.8. The pgpro_stats_vacuum_indexes View

> **Important**
>
> Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view pg_stats_vacuum_indexes (see System Views for details).

The pgpro_stats_vacuum_indexes view will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index. These statistics are collected by the core system as explained in Section 28.2. The table below describes the columns of the view.

Table G.88. pgpro_stats_vacuum_indexes Columns

Column	Type	Description
relid	oid	OID of an index
schema	name	Name of the schema this index is in
relname	name	Name of this index
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this index
total_blks_hit	int8	Number of times database blocks were found in the buffer cache

Column	Type	Description
		by vacuum operations performed on this index
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this index
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this index
rel_blks_read	int8	Number of blocks vacuum operations read from this index
rel_blks_hit	int8	Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_deleted	int8	Number of pages deleted by vacuum operations performed on this index
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this index
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this index
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this index
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this index
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see Section 19.4.4 for details)
system_time	float8	System CPU time of vacuuming this index, in milliseconds

Column	Type	Description
user_time	float8	User CPU time of vacuuming this index, in milliseconds
total_time	float8	Total time of vacuuming this index, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this index were interrupted on any errors

G.6.5. Data Types

G.6.5.1. The pgpro_stats_rusage Type

pgpro_stats_rusage is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in Table G.89.

Table G.89. pgpro_stats_rusage Fields

Name	Type	Description
reads	bigint	Number of bytes read by the filesystem layer
writes	bigint	Number of bytes written by the filesystem layer
user_time	double precision	User CPU time used
system_time	double precision	System CPU time used
minflts	bigint	Number of page reclaims (soft page faults)
majflts	bigint	Number of page faults (hard page faults)
nswaps	bigint	Number of swaps
msgsnds	bigint	Number of IPC messages sent
msgrcvs	bigint	Number of IPC messages received
nsignals	bigint	Number of signals received
nvcsws	bigint	Number of voluntary context switches
nivcsws	bigint	Number of involuntary context switches

G.6.6. Functions

pgpro_stats_statements_reset(userid Oid, dbid Oid, queryid bigint, planid bigint, minmax_only boolean) returns timestamp with time zone

pgpro_stats_statements_reset discards statistics gathered so far by pgpro_stats corresponding to the specified userid, dbid, queryid, and planid. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. If all statistics in the pgpro_stats_statements view are discarded, it will also reset the statistics in the pgpro_stats_info view. When minmax_only is true only the values of minimum and maximum planning and execution time will be reset (i.e. min_plan_time, max_plan_time, min_exec_time and max_exec_time fields). The default value for minmax_only parameter is false. Time of last min/max reset performed is shown in minmax_stats_since field of the pgpro_stats_s-

tatements view. This function returns the time of a reset. This time is saved to stats_reset field of pgpro_stats_info view or to minmax_stats_since field of the pgpro_stats_statements view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

> **Note**
>
> As statistics in the pgpro_stats_vacuum_database, pgpro_stats_vacuum_tables, and pgpro_stats_vacuum_indexes views are collected by the core system, to reset them, call the pg_stat_reset() function (see Section 28.2.28 for details).

`pgpro_stats_statements(showtext boolean) returns setof record`

The pgpro_stats_statements view is defined in terms of a function also named pgpro_stats_statements. Users can also call the pgpro_stats_statements function directly, and by specifying showtext := false make query text be omitted (that is, the OUT argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all pgpro_stats itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the pgpro_stats_statements data.

`pgpro_stats_info() returns record`

pgpro_stats_info view is defined in terms of a function also named pgpro_stats_info. Users can also call the pgpro_stats_info function directly.

`pgpro_stats_totals_reset(type text, id bigint) returns timestamp with timezone`

pgpro_stats_totals_reset discards statistics gathered so far by pgpro_stats corresponding to the specified object type and id. If no parameter is specified or the type parameter is set to 0, all statistics will be discarded. If type is set to a valid object type, then if id is specified, then statistics will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. This function returns the time of a reset. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

`pgpro_stats_totals() returns setof record`

The pgpro_stats_totals view is defined in terms of a function also named pgpro_stats_totals. Users can also call the pgpro_stats_totals function directly.

`pgpro_stats_metrics() returns setof record`

Defines the pgpro_stats_metrics view, which is described in detail in Table G.84.

`pgpro_stats_get_archiver() returns setof record`

Defines the pgpro_stats_archiver view, which is described in detail in Table G.85.

`pgpro_stats_wal_sender_crc_errors() returns bigint`

In Postgres Pro Enterprise, returns the number of errors detected by the WAL sender process when the wal_sender_check_crc parameter is on. In Postgres Pro Standard, returns zero. Note that this counter is reset to zero when the cluster restarts.

`pgpro_stats_vacuum_database(dboid oid) returns setof record`

Defines the row of the pgpro_stats_vacuum_database view, which is described in detail in Table G.86, for the database specified by *dboid*.

`pgpro_stats_vacuum_tables(dboid oid, relid oid) returns setof record`

Defines the row of the `pgpro_stats_vacuum_tables` view, which is described in detail in Table G.87, for the database specified by *`dboid`* and table specified by *`reloid`*. If *`reloid`* = 0, the statistics for each table in the specified database are returned.

`pgpro_stats_vacuum_indexes(dboid oid, relid oid) returns setof record`

Defines the row of the `pgpro_stats_vacuum_indexes` view, which is described in detail in Table G.88, for the database specified by *`dboid`* and index specified by *`reloid`*. If *`reloid`* = 0, the statistics for each index in the specified database are returned.

G.6.6.1. Functions for Creating Views that Emulate Other Extensions

pgpro_stats can create views similar to those available in pg_stat_statements and *pg_stat_kcache* extensions. Specifically, `pg_stat_statements`, `pg_stat_statements_info`, `pg_stat_kcache` and `pg_stat_kcache_detail` views can be created. Each view is only created in a Postgres Pro version if it is available in pg_stat_statements/pg_stat_kcache extension for the same version of Postgres Pro/PostgreSQL. For example, the `pg_stat_statements_info` view is only created in Postgres Pro versions starting with 14. The following functions enable creating these views:

`pgpro_stats_create_pg_stat_statements_compatible_views() returns void`

Creates `pg_stat_statements` and `pg_stat_statements_info` views.

`pgpro_stats_create_pg_stat_kcache_compatible_views() returns void`

Creates `pg_stat_kcache` and `pg_stat_kcache_detail` views.

By default, these functions can only be executed by superusers. Access may be granted to others using `GRANT`.

To create `pg_stat_statements*` views, drop the pg_stat_statements extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_statements_compatible_views();
```

To create `pg_stat_kcache*` views, drop the pg_stat_kcache extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_kcache_compatible_views();
```

Once the views are created, you can work with them as if the pg_stat_statements/pg_stat_kcache extension is installed.

If you need to remove the views created earlier, do it in a regular way:

```
drop view pg_stat_statements;
drop view pg_stat_statements_info;
drop view pg_stat_kcache;
drop view pg_stat_kcache_detail;
```

G.6.7. Configuration Parameters

G.6.7.1. General Settings

`pgpro_stats.max` (`integer`)

pgpro_stats only collects statistics about most frequent queries. The less frequently a query appears during the server opertaion, the less probable its inclusion in the statistics. Rare queries are almost immediately evicted from the statistics by more frequent queries. The `pgpro_stats.max` parameter defines the maximum number of unique pairs (normalized query text, normalized plan text) tracked by the module, (i.e., the maximum number of rows in the `pgpro_stats_statements` view). The larger this value, the larger the number of queries for which the information is stored. But this is achieved at the cost of reduced server performance when waiting for locks trying to access the statistics table

in the shared memory and when periodically collecting garbage in the file with texts of queries and plans. The default value is 5000. This parameter can only be set at server start.

`pgpro_stats.max_totals` (`integer`)

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

`pgpro_stats.track` (`enum`)

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions) with nesting level not greater than 100, or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pgpro_stats.track_utility` (`boolean`)

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_planning` (`boolean`)

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pgpro_stats_statements` entries. The default value is `off`. Only superusers can change this setting.

`pgpro_stats.track_totals` (`boolean`)

`pgpro_stats.track_totals` controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_cluster` (`boolean`)

`pgpro_stats.track_cluster` controls whether aggregate statistics for the cluster are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_databases` (`boolean`)

`pgpro_stats.track_databases` controls whether aggregate statistics for the databases are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_users` (`boolean`)

`pgpro_stats.track_users` controls whether aggregate statistics for the users are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_applications` (`boolean`)

`pgpro_stats.track_applications` controls whether aggregate statistics for the applications (whose names are set by application_name) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_client_addr` (`boolean`)

`pgpro_stats.track_client_addr` controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_backends` (`boolean`)

`pgpro_stats.track_backends` controls whether aggregate statistics for the backends are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_sessions` (`boolean`)

`pgpro_stats.track_sessions` controls whether aggregate statistics for the sessions are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.save` (`boolean`)

`pgpro_stats.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are neither saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`pgpro_stats.plan_format` (`text`)

`pgpro_stats.plan_format` selects the `EXPLAIN` format for the query plan. Possible values are `text`, `xml`, `json`, and `yaml`. The default value is `text`. Changing this parameter requires a server restart.

`pgpro_stats.enable_profile` (`boolean`)

`pgpro_stats.enable_profile` enables sampling of wait events for separate statements. The default value is `true`. Changing this parameter requires a server restart.

`pgpro_stats.query_sample_rate` (`float`)

As pgpro_stats only collects statistics about most frequent queries, and rare queries are not included in the statistics, you can reduce the effect of the statistics collection on the server performance. This is possible because some time later than the statistics collection starts, almost all the statistics collected by the module will contain queries that are not very infrequent, and the set of types of the collected queries will not further change much if the value of pgpro_stats.max is sufficient and the average frequency for most of the frequent queries has no significant changes with the periods larger than the observation time. Such a stationary distribution of collected queries can also be achieved by increasing the time of the statistics collection, for example, twice, but only adding each second query to the statistics instead of every query, or considering each query, but adding queries to the statistics randomly, with a given probability. In this example, it equals 0.5. This allows you to considerably reduce the server load at the cost of increasing the time of the statistics collection. `pgpro_stats.query_sample_rate` is the parameter to implement this approach. For example: if `pgpro_stats.query_sample_rate` is set to 0.2 (1/5), in five hours of the server operation under the above conditions, the statistics will be collected that is similar to the statistics collected with `pgpro_stats.query_sample_rate` = 1 in an hour.

You can set up `pgpro_stats.query_sample_rate` by experiment. Choose the observation time depending on the environment of the server operation, for example: one hour. Look at the collected statistics an hour after the start and then an hour later without resetting the statistics. If the main difference appears to be in the increased number of collected queries (`calls`) rather than in the type of the queries, you can safely reduce `pgpro_stats.query_sample_rate` twice. In the case of a considerable difference in the types of the collected queries, increase the observtion time and/or the `pgpro_stats.max` parameter.

The default value is `1.0`. Changing this parameter requires a server restart.

`pgpro_stats.profile_period` (`integer`)

`pgpro_stats.profile_period` specifies the period, in milliseconds, during which to sample wait events. The default value is `10`. Only superusers can change this setting.

`pgpro_stats.metrics_buffer_size` (`integer`)

`pgpro_stats.metrics_buffer_size` specifies the size of the ring buffer used for collecting statistical metrics. The default value is `16kB`. Changing this parameter requires a server restart.

`pgpro_stats.metrics_workers` (`integer`)

`pgpro_stats.metrics_workers` specifies the number of workers used to collect statistical metrics. If this parameter is set to 2 or higher, one of the workers serves as the primary worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different

databases. Setting this parameter to `0` disables metrics collection. The default value is `2`. Changing this parameter requires a server restart.

`pgpro_stats.stats_temp_directory` (`string`)

`pgpro_stats.stats_temp_directory` specifies the directory with the external file to store query texts. This can be a path relative to the data directory or an absolute path. Changing this parameter requires a server restart.

G.6.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The *N* placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect. Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

`pgpro_stats.metric_N_name` (`text`)

The name of metric *N*. This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

`pgpro_stats.metric_N_query` (`text`)

The query statement that defines the metric to collect.

`pgpro_stats.metric_N_period` (`integer`)

The time interval at which to collect metric *N*, in milliseconds. Default: 60000 ms

`pgpro_stats.metric_N_db` (`text`)

The list of databases for which to collect metric *N*. Database names must be separated by commas. You can specify the `*` character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

`pgpro_stats.metric_N_user` (`text`)

The name of the user on behalf of which to collect metric *N*. This user must have access to the database for which the metric is collected.

G.6.8. Tracing of Application Sessions

In pgpro_stats, tracing of application sessions is implemented. It is based on filters, which trigger logging the execution of queries that match filtering conditions. Queries and their `EXPLAIN` output are logged in so-called *trace files* specified by the user or in the system log file (if the trace file is not specified). Filters are stored in a table located in the shared memory. The rows of this table represent filters, and the columns contain filtering conditions and `EXPLAIN` options to be used (see EXPLAIN for details). You should fill this table with filters to start tracing of queries.

Once a database administrator adds a filter in any session, all subsequent executions of queries that match the filter conditions will be traced by all sessions of the instance without a need in the server restart. In other words, filters can be added, deleted, or updated “on the fly”, and tracing with these filters immediately starts for existing and future sessions.

> **Note**
>
> Operations of adding, deleting, or updating filters are not transactional. Changes to the table of filters are not rolled back together with the transaction where these changes were made.

Columns of the table that stores filters are also called *filter attributes*. They are described in Table G.90.

Table G.90. Filter Attributes

Name	Type	Description
filter_id	integer	Unique filter ID, which is automatically assigned to a filter when it is created, numbered from 1.
active	boolean	With the value of false, the filter is not active, which means that queries matching this filter are not logged. Default: true.
alias	name	Filter name, which can be specified for convenience. Only shown in the output of the pgpro_stats_trace_show() function. Default: empty string.
tracefile	name	Name of the trace file, where queries matching the filter and their EXPLAIN output are logged. If this filename if not specified, logging is done to the system log with the log level specified by pgpro_stats.trace_log_level. Trace files are created in PGDATA/pg_stat directory and have trace extension.
pid	integer	Process ID of the backend that executes the statement
database_name	name	Name of the database where the statement is executed
client_addr	name	IP address of the client connected to this backend
application_name	name	Name of the application that invoked execution of the statement
username	name	Name of the user who executes the statement
queryid	bigint	Internal hash code, computed from the statement's parse tree
planid	bigint	Internal hash code, computed from the statement's plan tree
duration	float8	Time spent in the planning and execution of the statement, in milliseconds
plan_time	float8	Time spent in the planning of the statement, in milliseconds
exec_time	float8	Time spent in the execution of the statement, in milliseconds
user_time	float8	User CPU time used in planning and execution of the statement
system_time	float8	System CPU time used in planning and execution of the statement

Name	Type	Description
rows	int8	Total number of rows retrieved or affected by the statement
shared_blks_hit	int8	Total number of shared block cache hits by the statement
shared_blks_read	int8	Total number of shared blocks read by the statement
shared_blks_fetched	int8	Total number of shared blocks fetched from buffers by the statement
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statement
shared_blks_written	int8	Total number of shared blocks written by the statement
local_blks_hit	int8	Total number of local block cache hits by the statement
local_blks_read	int8	Total number of local blocks read by the statement
local_blks_fetched	int8	Total number of local blocks fetched from buffers by the statement
local_blks_dirtied	int8	Total number of local blocks dirtied by the statement
local_blks_written	int8	Total number of local blocks written by the statement
temp_blks_read	int8	Total number of temp blocks read by the statement
temp_blks_written	int8	Total number of temp blocks written by the statement
wal_bytes	numeric	Total amount of WAL bytes generated by the statement
total_wait_time	float8	Total time execution of this statement spent waiting
total_inval_msgs	bigint	Total number of cache invalidation messages generated by the statement (if this is supported by the server)
explain_analyze	boolean	If true, the EXPLAIN output will be logged with the ANALYZE option. By default, defined by the pgpro_stats.explain_analyze_default configuration parameter.
explain_verbose	boolean	If true, the EXPLAIN output will be logged with the VERBOSE option. By default, defined by the pgpro_stats.explain_verbose_default configuration parameter.
explain_costs	boolean	If true, the EXPLAIN output will be logged with the COSTS option. By default, defined by the pgpro_

Name	Type	Description
		stats.explain_costs_default configuration parameter.
explain_settings	boolean	If true, the EXPLAIN output will be logged with the SETTINGS option. By default, defined by the pgpro_stats.explain_settings_default configuration parameter.
explain_buffers	boolean	If true, the EXPLAIN output will be logged with the BUFFERS option. By default, defined by the pgpro_stats.explain_buffers_default configuration parameter.
explain_wal	boolean	If true, the EXPLAIN output will be logged with the WAL option. By default, defined by the pgpro_stats.explain_wal_default configuration parameter.
explain_timing	boolean	If true, the EXPLAIN output will be logged with the TIMING option. By default, defined by the pgpro_stats.explain_timing_default configuration parameter.
explain_format	text	The value of the FORMAT option of EXPLAIN to be logged, which can be TEXT, XML, JSON, or YAML. By default, defined by the pgpro_stats.plan_format configuration parameter.
time_info	boolean	If true, includes additional information in the session-tracing output in the format defined by explain_format : pid, duration in milliseconds, start time — start time of the query execution, and stop time — end time of the query execution. See Example G.2 for details.

Filter attributes can be divided into the following groups:

- Control attributes, from filter_id to tracefile in Table G.90.
- Identification attributes, from pid to planid in Table G.90.
- Threshold attributes, from duration to total_inval_msgs in Table G.90.
- Attributes that only control the output to the trace file or system log file and do not affect filtering. Most of them specify the EXPLAIN options. These are the attributes starting with explain_analyze up to the end of Table G.90.

Query execution will be traced if both of these conditions are met:

- For all the specified identification attributes of the filter, the values of the respective characteristics of the query are the same as the values of these attributes.
- For all the specified threshold attributes of the filter, the values of the respective characteristics of the query are greater than or equal to the limits specified in these attributes.

It is allowed not to assign values to attributes. For all the attributes except `active`, you can also explicitly assign the value of NULL. If the value of a control attribute is undefined or it was expclicitly set to NULL, this attribute will be assigned the default value shown in Table G.90. For identification and threshold attributes, undefined or NULL values mean that queries will not be filtered by the respective characteristic. If no values are defined for all identification and all threshold attributes, all the queries are taken to be matching this filter and will be logged. If the attributes specifying `EXPLAIN` options are undefined, the default values defined by the configuration parameters will be used (see Section G.6.8.2 for details).

> **Warning**
>
> Although when specifying a filter, you can assign values to any combination of filter attributes, bear in mind that a too general filter will lead to an excessive size of the trace file and will affect the performance more than desired as the main performance overhead is associated with writing to the trace file rather than with checking the filter conditions.

G.6.8.1. Session-Tracing Functions

Specialized functions enable creation, update and deletion of query filters:

`pgpro_stats_trace_insert(VARIADIC "any") returns integer`

Adds a filter to the list of session-tracing filters. A filter must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from Table G.90 except `filter_id`. For example:

```
pgpro_stats_trace_insert('pid', 42, 'database_name', 'main', 'explain_analyze',
 true)
```

Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in Table G.90. Some of the attributes can be missing from the sequence. Such attributes will be assigned the default values. Returns the unique `filter_id`, which the function assigns to the added filter.

`pgpro_stats_trace_update(filter_id integer, VARIADIC "any") returns boolean`

Updates a session-tracing filter defined by *`filter_id`*. Filter attributes to update must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from Table G.90 except `filter_id`. Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in Table G.90. Filter attributes whose values are not explicitly specified will not be changed. The value of NULL for identification and threshold attributes resets the values of these attributes, which means that a query will match the conditions of the updated filter regardless of the respective characteristics. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_delete(filter_id integer) returns boolean`

Deletes a session-tracing filter defined by *`filter_id`*. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_reset() returns integer`

Removes all session-tracing filters. Returns the number of removed filters. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_trace_show() returns setof record`

Displays the contents of the table of filters, whose columns are shown in Table G.90.

G.6.8.2. Session-Tracing Configuration Parameters

The following parameters can be used to configure session-tracing logging. Note that `pgpro_stats.explain_*_default` settings define the logging behavior when the corresponding `explain_*` filter attributes (from Table G.90) are not specified or explicitly set to NULL.

`pgpro_stats.explain_analyze_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `ANALYZE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_verbose_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `VERBOSE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_costs_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `COSTS` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.explain_settings_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `SETTINGS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_buffers_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `BUFFERS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_wal_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `WAL` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_timing_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `TIMING` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.trace_log_level` (`enum`)

Defines the log level at which the `EXPLAIN` output will be logged to the system log file (when the trace file is not specified). Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default value is `LOG`.

`pgpro_stats.trace_query_text_size` (`int`)

Defines the maximum size of query texts in the session-tracing output, in kilobytes. If the size of the query text in kilobytes is larger, it is trimmed to the maximum size. If this parameter is not specified, the default value of zero is used, which means that the whole query texts are output.

G.6.8.3. Examples Related to Session Tracing

Example G.1. Usage of Session-Tracing Functions

Let's add the filter `first`:

```
SELECT pgpro_stats_trace_insert('alias', 'first', 'pid', pg_backend_pid(),
 'explain_analyze', true);
```

Let's add the filter `second` and specify logging to the trace file `second_tf.trace`:

```
SELECT pgpro_stats_trace_insert('alias', 'second', 'database_name', current_database(),
 'explain_costs', false, 'tracefile', 'second_tf');
```

You can view the table with filters as follows:

```
\x auto
```

```
SELECT * from pgpro_stats_trace_show();

-[ RECORD 1 ]-------+----------
filter_id           | 1
active              | t
alias               | first
tracefile           |
pid                 | 243183
database_name       |
client_addr         |
application_name    |
username            |
queryid             |
planid              |
duration            |
plan_time           |
exec_time           |
user_time           |
system_time         |

shared_blks_hit     |
shared_blks_read    |
shared_blks_fetched |
shared_blks_dirtied |
shared_blks_written |
local_blks_hit      |
local_blks_read     |
local_blks_fetched  |
local_blks_dirtied  |
local_blks_written  |
temp_blks_read      |
temp_blks_written   |
wal_bytes           |
total_wait_time     |
total_inval_msgs    |
explain_analyze     | t
explain_verbose     | f
explain_costs       | t
explain_settings    | f
explain_buffers     | f
explain_wal         | f
explain_timing      | t
explain_format      | text
time_info           | f
-[ RECORD 2 ]-------+----------
filter_id           | 2
active              | t
alias               | second
tracefile           | second_tf
pid                 |
database_name       | postgres
client_addr         |
application_name    |
username            |
queryid             |
planid              |
duration            |
plan_time           |
```

```
exec_time           |
user_time           |
system_time         |
rows                |
shared_blks_hit     |
shared_blks_read    |
shared_blks_fetched |
shared_blks_dirtied |
shared_blks_written |
local_blks_hit      |
local_blks_read     |
local_blks_fetched  |
local_blks_dirtied  |
local_blks_written  |
temp_blks_read      |
temp_blks_written   |
wal_bytes           |
total_wait_time     |
total_inval_msgs    |
explain_analyze     | f
explain_verbose     | f
explain_costs       | f
explain_settings    | f
explain_buffers     | f
explain_wal         | f
explain_timing      | f
explain_format      | text
time_info           | f
```

The following query matches the conditions of both filters, so it must be logged in the system log file and in the specified trace file:

```
SELECT 1 as result;
```

The following is the output to the system log file:

```
2023-04-18 04:52:53.242 MSK [63112] LOG:  Filter 1 triggered explain of the plan:
Query Text: SELECT 1 as result;
Result  (cost=0.00..0.01 rows=1 width=4) (actual time=0.003..0.003 rows=1 loops=1)
```

And the following is the output to the `second_tf.trace` trace file:

```
Query Text: SELECT 1 as result;
Result
```

Let's delete the first filter:

```
SELECT pgpro_stats_trace_delete(1);
```

Let's also change `pid` to 2 for the second filter

```
SELECT pgpro_stats_trace_update(2, 'pid', 2);
```

When you execute the query

```
SELECT 2 as result;
```

it does not get logged to `second_tf.trace`.

Now let's remove all filters from the table:

```
SELECT pgpro_stats_trace_reset();
```

Example G.2. Session-Tracing Output with `time_info` = `true`

The following is an example of the session-tracing output in the JSON format when `time_info` = `true`:

```
  {
```

```
    "Pid": 123456,
    "Duration ms": 0.094691,
    "Start time": "2025-01-12 15:39:27.580447+03",
    "Stop time": "2025-01-12 15:39:27.587802+03",
    "Query Text": "SELECT 2 AS Result;",
    "Plan": {
      "Node Type": "Result",
      "Parallel Aware": false,
      "Async Capable": false,
      "Startup Cost": 0.00,
      "Total Cost": 0.01,
      "Plan Rows": 1,
      "Plan Width": 4
    }
  }
```

G.6.9. Cache Invalidation Metrics

Among the rest, pgpro_stats can collect cache invalidation statistics. This section provides some background information needed to better understand related metrics.

Each backend has its local cache, which allows you to minimize accesses for meta information on tables, for example, to the system catalogs. If a backend changes the meta information, this information must be updated in other backends' caches. This is implemented by sending invalidation messages through a queue: the backend that changed the meta information on some object sends an appropriate message to the queue.

All backends get invalidation messages from the queue. Depending on whether the object for which the invalidation message was received is cached, the backend either ignores the message (when the object is not cached) or updates its cache (when the object is cached). In pgpro_stats, most invalidation message counters, unless explicitly stated otherwise for certain counters, are incremented when backends just generate messages, which will only be sent to the queue upon commit of the appropriate transaction. Note that the counters will remain incremented if the transaction is rolled back, although the message will not be sent to the queue.

When a backend that is adding messages to the queue figures out that the queue size reached a certain limit, it starts a cleanup by deleting messages already processed by all backends, and if backends are found that heavily fall behind and thus delay the cleanup, they get a reset signal, which forces them to reset all their caches.

G.6.9.1. The `pgpro_stats_inval_status` View

The `pgpro_stats_inval_status` view shows one row with the current status of the cache invalidation global queue. The columns of the view are shown in Table G.91.

Table G.91. `pgpro_stats_inval_status` Columns

Name	Type	Description
`num_inval_messages`	`int8`	Current number of invalidation messages in the queue
`num_inval_queue_cleanups`	`int8`	Number of invalidation queue cleanups done to prevent its overflow
`num_inval_queue_resets`	`int4`	Number of cache resets for backends that fail to process messages fast enough

In a working system, `num_inval_messages` usually approximately equals 4000, which means that the queue is pretty full. The speed of the `num_inval_queue_cleanups` growth is determined by how fast invalidation messages are generated. Growth of `num_inval_queue_resets` is normally zero, and non-zero

growth indicates either too fast generation of messages or delays in processing messages by backends. Monitoring num_inval_queue_cleanups and num_inval_queue_resets may in some cases allow you to detect problematic backend/backeds as described below.

If for a certain time interval, num_inval_queue_cleanups considerably increased, while num_inval_queue_resets did not, this indicates that invalidation messages are generated faster and/or backends process them more slowly, but backends still manage to process messages before the queue overflows.

If for a time interval, num_inval_queue_cleanups did not considerably increase, while num_inval_queue_resets did, this definitely indicates a delay in processing messages by backend(s), and the cache_resets column of the pgpro_stats_totals view allows you to figure out which backend(s) to blame.

If for a time interval, both counters considerably increased, this also indicates that invalidation messages are generated faster and/or backends process them more slowly, but this time backends fail to process messages before the queue overflows. The cache_resets column of the pgpro_stats_totals view allows you detect which backend(s) delay message processing. In this case, it is not possible to definitely conclude whether too fast generation of messages or a delay in message processing accounts for the growth of num_inval_queue_resets. However, the totals counter of the pgpro_stats_inval_msgs view may help here. If the change of this counter for that interval is pretty the same as for a previous interval of the same length, you can definitely conclude that the growth is caused by backend delays.

The pgpro_stats_inval_status view can be defined in terms of a function:

pgpro_stats_inval_status() returns record

Defines the pgpro_stats_inval_status view, which is described in detail in Table G.91.

G.6.9.2. The pgpro_stats_inval_msgs Type

The pgpro_stats_statements and pgpro_stats_totals views for each corresponding object, show a record of the pgpro_stats_inval_msgs record type containing counters for cache invalidation messages. The fields of the type are shown in Table G.92.

Table G.92. pgpro_stats_inval_msgs Fields

Name	Type	Description
total	bigint	Total number of invalidation messages
catcache	bigint	Number of selective catalog cache invalidation messages
catalog	bigint	Number of whole catalog cache invalidation messages
relcache	bigint	Number of selective relation cache invalidation messages
relcache_all	bigint	Number of whole relation cache invalidation messages
smgr	bigint	Number of invalidation messages of open relation files. Gets incremented when the messages are sent to the queue.
relmap	bigint	Number of relation map cache invalidation messages. Gets incremented when the messages are sent to the queue.
snapshot	bigint	Number of catalog snapshot invalidation messages

G.6.10. Authors

Postgres Professional, Moscow, Russia

G.7. sr_plan — save a specific plan of a parameterized query for future usage

> **Important**
>
> The sr_plan extension is considered deprecated. Use the pgpro_multiplan extension instead.

G.7.1. Description

sr_plan allows the user to save query execution plans and utilize these plans for subsequent executions of the same queries, thereby avoiding repeated optimization of identical queries.

sr_plan looks like Oracle Outline system. It can be used to lock the execution plan. It could help if you do not trust the planner.

G.7.2. Installation

The sr_plan extension is provided with Postgres Pro Enterprise as a separate pre-built package `sr-plan-ent-16` (for the detailed installation instructions, see Chapter 17). To enable sr_plan, complete the following steps:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'sr_plan'
   ```

   Note that the library names in the `shared_preload_libraries` variable must be added in the specific order, for information on compatibility of sr_plan with other extensions, see Section G.7.5.

2. Reload the database server for the changes to take effect.

   To verify that the `sr_plan` library was installed correctly, you can run the following command:

   ```
   SHOW shared_preload_libraries;
   ```

3. Create the `sr_plan` extension using the following query:

   ```
   CREATE EXTENSION sr_plan;
   ```

   It is essential that the library is preloaded during server startup because sr_plan has a shared memory cache that can be initialized only during startup. The sr_plan extension should be created in each database where query management is required.

4. Enable the sr_plan extension, which is disabled by default, in one of the following ways:

   - To enable sr_plan for all backends, set `sr_plan.enable = true` in the `postgresql.conf` file.
   - To activate sr_plan in the current session, use the following command:

     ```
     SET sr_plan.enable TO true;
     ```

5. If you want to transfer sr_plan data from the primary to a standby using physical replication, set the sr_plan.wal_rw parameter to `on` on both servers. In this case, ensure that the same sr_plan versions are installed on both primary and standby, otherwise correct replication workflow is not guaranteed.

G.7.3. Usage

sr_plan allows you to freeze plans for future usage. Freezing involves three stages:

1. Registering the query for which you want to freeze the plan.
2. Modifying the query execution plan.
3. Freezing the query execution plan.

G.7.3.1. Registering a Query

There are two ways to register a query:

- Using the sr_register_query() function:

  ```
  SELECT sr_register_query(query_string, parameter_type, ...);
  ```

  Here *query_string* is your query with `$n` parameters (same as in `PREPARE statement_name AS`). You can describe each parameter type with the optional *parameter_type* argument of the function or choose not to define parameter types explicitly. In the latter case, Postgres Pro attempts to determine each parameter type from the context. This function returns the unique pair of `sql_hash` and `const_hash`. Now sr_plan will track executions of queries that fit the saved parameterized query template.

  ```
  -- Create table 'a'
  CREATE TABLE a AS (SELECT * FROM generate_series(1,30) AS x);
  CREATE INDEX ON a(x);
  ANALYZE;

  -- Register the query
  SELECT sql_hash, const_hash
  FROM sr_register_query('SELECT count(*) FROM a
  WHERE x = 1 OR (x > $2 AND x < $1) OR x = $1', 'int', 'int')
         sql_hash       | const_hash
  ----------------------+------------
    5393873830515778388 |  15498345
  (1 row)
  ```

- Using the sr_plan.auto_tracking parameter:

  ```
  -- Set sr_plan.auto_tracking to on
  SET sr_plan.auto_tracking = on;

  -- Execute EXPLAIN for a non-parameterized query

  EXPLAIN SELECT count(*) FROM a WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

  Custom Scan (SRScan)  (cost=1.60..0.00 rows=1 width=8)
    Plan is: tracked
    SQL hash: 5393873830515778388
    Const hash: 0
    ->  Aggregate  (cost=1.60..1.61 rows=1 width=8)
          ->  Seq Scan on a  (cost=0.00..1.60 rows=2 width=0)
                Filter: ((x = $1) OR ((x > $2) AND (x < $3)) OR (x = $4))
  ```

G.7.3.2. Modifying the Query Execution Plan

A query execution plan can be modified using optimizer variables, pg_hint_plan hints if the extension is enabled, or other extensions that allow changing the query plan, such as aqo. For information on compatibility of sr_plan with other extensions, see Section G.7.5.

G.7.3.3. Freezing the Query Execution Plan

To freeze a modified query plan, use the sr_plan_freeze function. The optional parameter *plan_type* can be set to either `serialized` or `hintset`. The default value is `serialized`. For detailed information on types of frozen plans, see Section G.7.4.

G.7.3.4. Usage Example

The below example illustrates the usage of sr_plan.

```
CREATE EXTENSION sr_plan;
SET sr_plan.enable = ON;

-- Register the query
SELECT sql_hash, const_hash
FROM sr_register_query('SELECT count(*) FROM a
WHERE x = 1 OR (x > $2 AND x < $1) OR x = $1', 'int', 'int');
       sql_hash      | const_hash
---------------------+------------
 5393873830515778388 | 15498345
(1 row)

-- Modify the query execution plan
SET enable_seqscan = 'off';

EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

                                QUERY PLAN
-------------------------------------------------------------------------
 Custom Scan (SRScan) (actual rows=1 loops=1)
   Plan is: tracked
   SQL hash: 5393873830515778388
   Const hash: 15498345
   ->  Aggregate (actual rows=1 loops=1)
         ->  Index Only Scan using a_x_idx on a (actual rows=12 loops=1)
               Filter: ((x = 1) OR ((x > $2) AND (x < $1)) OR (x = $1))
               Rows Removed by Filter: 18
               Heap Fetches: 30
 Planning Time: 1.085 ms
 Execution Time: 0.085 ms
(11 rows)

-- Freeze the query execution plan
SELECT sr_plan_freeze();
RESET enable_seqscan;

-- Now the frozen plan is used
EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

                                QUERY PLAN
-------------------------------------------------------------------------
 Custom Scan (SRScan) (actual rows=1 loops=1)
   Plan is: frozen, serialized
   SQL hash: 5393873830515778388
   Const hash: 15498345
   ->  Aggregate (actual rows=1 loops=1)
         ->  Index Only Scan using a_x_idx on a (actual rows=12 loops=1)
               Filter: ((x = 1) OR ((x > $2) AND (x < $1)) OR (x = $1))
               Rows Removed by Filter: 18
               Heap Fetches: 30
 Planning Time: 0.327 ms
 Execution Time: 0.081 ms
(11 rows)
```

G.7.4. Frozen Plan Types

There are two types of frozen plans: serialized plans and hint-set plans.

- A `serialized` plan is a serialized representation of the plan. This plan is transformed into an executable plan upon the first match of the corresponding frozen query. The serialized plan remains valid as long as the query metadata (table structures, indexes, etc.) remain unchanged. For example, if a table present in the frozen plan is recreated, the frozen plan becomes invalid and is ignored. The serialized plan is only valid within the current database and cannot be copied to another, as it depends on OIDs. For this reason, using a serialized plan for temporary tables is impractical.
- A `hintset` plan is a set of hints that are formed based on the execution plan at the time of freezing. The set of hints consists of optimizer environment variables differing from default values, join types, join orders, and data access methods. These hints correspond to those supported by the pg_hint_plan extension. To use hint-set plans, pg_hint_plan must be enabled. The set of hints is passed to the pg_hint_plan planner upon the first match of the corresponding frozen query, and pg_hint_plan generates the executable plan. If the pg_hint_plan extension is not active, the hints are ignored, and the plan generated by the Postgres Pro optimizer is executed. Hint-set plans do not depend on object identifiers and remain valid when tables are recreated, fields are added, etc.

G.7.5. Compatibility with Other Extensions

To ensure compatibility of sr_plan with other enabled extensions, specify the library names in the `shared_preload_libraries` variable in the `postgresql.conf` file in the specific order:

- pg_hint_plan: sr_plan must be loaded after pg_hint_plan.

  ```
  shared_preload_libraries = 'pg_hint_plan, sr_plan'
  ```

- aqo: sr_plan must be loaded before aqo.

  ```
  shared_preload_libraries = 'sr_plan, aqo'
  ```

- pgpro_stats: sr_plan must be loaded after pgpro_stats.

  ```
  shared_preload_libraries = 'pgpro_stats, sr_plan'
  ```

G.7.6. Frozen Query Identification

A frozen query in the current database is identified by a combination of `sql_hash` and `const_hash`.

`sql_hash` is a hash generated based on the parse tree, ignoring parameters and constants. Field and table aliases are not ignored. Therefore, the same query with different aliases will have different `sql_hash` values.

`const_hash` is a hash generated based on all constants involved in the query. Constants with the same value but different types, such as `1` and `'1'`, will produce different hash values.

G.7.7. Automatic Type Casting

sr_plan automatically attempts to cast the types of constants involved in the query to match the parameter types of the frozen query. If type casting is not possible, the frozen plan is ignored.

```
SELECT sql_hash, const_hash
FROM sr_register_query('SELECT count(*) FROM a
WHERE x = $1', 'int');

-- Type casting is possible
EXPLAIN SELECT count(*) FROM a WHERE x = '1';
                      QUERY PLAN
-------------------------------------------------------------
```

```
Custom Scan (SRScan)  (cost=1.38..0.00 rows=1 width=8)
  Plan is: tracked
  SQL hash: -5166001356546372387
  Const hash: 0
  ->  Aggregate  (cost=1.38..1.39 rows=1 width=8)
        ->  Seq Scan on a  (cost=0.00..1.38 rows=1 width=0)
              Filter: (x = $1)

-- Type casting is possible
EXPLAIN SELECT count(*) FROM a WHERE x = 1::bigint;
                      QUERY PLAN
-------------------------------------------------------------
Custom Scan (SRScan)  (cost=1.38..0.00 rows=1 width=8)
  Plan is: tracked
  SQL hash: -5166001356546372387
  Const hash: 0
  ->  Aggregate  (cost=1.38..1.39 rows=1 width=8)
        ->  Seq Scan on a  (cost=0.00..1.38 rows=1 width=0)
              Filter: (x = $1)

-- Type casting is impossible
EXPLAIN SELECT count(*) FROM a WHERE x = 1111111111111;
                   QUERY PLAN
-----------------------------------------------------
 Aggregate  (cost=1.38..1.39 rows=1 width=8)
   ->  Seq Scan on a  (cost=0.00..1.38 rows=1 width=0)
         Filter: (x = '1111111111111'::bigint)
```

G.7.8. Views

G.7.8.1. The `sr_plan_storage` View

The `sr_plan_storage` view provides detailed information about all frozen statements. The columns of the view are shown in Table G.93.

Table G.93. `sr_plan_storage` Columns

Name	Type	Description
`dbid`	`oid`	ID of the database where the statement is executed
`sql_hash`	`bigint`	Internal query ID
`const_hash`	`bigint`	Hash of non-parameterized constants
`valid`	`boolean`	`FALSE` if the plan was invalidated the last time it was used
`query_string`	`text`	Query registered by the `sr_register_query` function
`paramtypes`	`regtype[]`	Array with parameter types used in the query
`query`	`text`	Internal representation of the query
`plan`	`text`	Internal representation of the plan
`hintstr`	`text`	Set of hints formed based on the frozen plan

G.7.8.2. The `sr_plan_local_cache` View

The `sr_plan_local_cache` view provides detailed information about registered and frozen statements in the local cache. The columns of the view are shown in Table G.94.

Table G.94. `sr_plan_local_cache` Columns

Name	Type	Description
`sql_hash`	`bigint`	Internal query ID
`const_hash`	`bigint`	Hash of non-parameterized constants
`fs_is_frozen`	`boolean`	`TRUE` if the statement is frozen
`fs_is_valid`	`boolean`	`TRUE` if the statement is valid
`ps_is_valid`	`boolean`	`TRUE` if the statement should be revalidated
`query_string`	`text`	Query registered by the `sr_register_query` function
`query`	`text`	Internal representation of the query
`paramtypes`	`regtype[]`	Array with parameter types used in the query
`hintstr`	`text`	Set of hints formed based on the frozen plan

G.7.8.3. The `sr_captured_queries` View

The `sr_captured_queries` view provides detailed information about all queries captured in sessions. The columns of the view are shown in Table G.95.

Table G.95. `sr_captured_queries` Columns

Name	Type	Description
`dbid`	`oid`	ID of the database where the statement is executed
`sql_hash`	`bigint`	Internal query ID
`queryid`	`bigint`	Standard query ID
`sample_string`	`text`	Query executed in the automatic query capture mode
`query_string`	`text`	Parameterized query
`constants`	`text`	Set of constants in the query
`prep_consts`	`text`	Set of constants used to `EXECUTE` a prepared statement
`hintstr`	`text`	Set of hints formed based on the plan
`explain_plan`	`text`	Plan shown by the `EXPLAIN` command

G.7.9. Functions

Only superuser can call the functions listed below.

`sr_register_query(query_string text) returns record`
`sr_register_query(query_string text, VARIADIC regtype[]) returns record`

Saves the query described in the *query_string* in the local cache and returns the unique pair of `sql_hash` and `const_hash`.

`sr_unregister_query() returns bool`

Removes the query that was registered but not frozen from the local cache. Returns true if there are no errors.

`sr_plan_freeze(plan_type text) returns bool`

Freezes the last used plan for the statement. The allowed values of the `plan_type` optional argument are `serialized` and `hintset`. The `serialized` value means that the query plan based on the serialized representation is used. With `hintset`, sr_plan uses the query plan based on the set of hints, which is formed at the stage of registered query execution. If the `plan_type` argument is omitted, the `serialized` query plan is used by default. Returns true if there are no errors.

`sr_plan_unfreeze(sql_hash bigint, const_hash bigint) returns bool`

Removes the plan only from the storage and keeps the query registered in the local cache. Returns true if there are no errors.

`sr_plan_remove(sql_hash bigint, const_hash bigint) returns bool`

Removes the frozen statement with the specified `sql_hash` and `const_hash`. Operates as `sr_plan_unfreeze` and `sr_unregister_query` called sequentially. Returns true if there are no errors.

`sr_plan_reset(dbid oid) returns bigint`

Removes all records in the sr_plan storage for the specified database. Omit *dbid* to remove the data collected by sr_plan for the current database. Set *dbid* to NULL to reset data for all databases.

`sr_reload_frozen_plancache() returns bool`

Drops all frozen plans and reloads them from the storage. It also drops statements that have been registered but not frozen.

`sr_plan_fs_counter() returns table`

Returns the number of times each frozen statement was used and the ID of the database where the statement was registered and used.

`sr_show_registered_query(sql_hash bigint, const_hash bigint) returns table`

Returns the registered query with the specified `sql_hash` and `const_hash` even if it is not frozen, for debugging purposes only. This works if the query is registered in the current backend or frozen in the current database.

`sr_set_plan_type(sql_hash bigint, const_hash bigint, plan_type text) returns bool`

Sets the type of the query plan for the frozen statement. The allowed values of the `plan_type` argument are `serialized` and `hintset`. To be able to use the query plan of the `hintset` type, the pg_hint_plan module must be loaded. Returns true if the plan type has been changed successfully.

`sr_plan_hintset_update(sql_hash bigint, const_hash bigint, hintset text) returns bool`

Allows to change the generated hint set with the set of custom hints. Custom hint-set string should not be enclosed in the special form of comment, as in pg_hint_plan, i.e. it should not start with `/*+` and end with `*/`. Returns `true` if the hint-set plan was changed successfully.

`sr_captured_clean() returns bigint`

Removes all records from the sr_captured_queries view. The function returns the number of removed records.

G.7.10. Configuration Parameters

`sr_plan.enable` (`boolean`)

Enables sr_plan to use frozen plans. The default value is `off`. Only superusers can change this setting.

`sr_plan.fs_ctr_max` (`integer`)

Sets the maximum number of frozen statements returned by the `sr_plan_fs_counter()` function. The default value is 5000. This parameter can only be set at server start.

`sr_plan.max_items` (`integer`)

Sets the maximum number of entries sr_plan can operate with. The default value is 100. This parameter can only be set at server start.

`sr_plan.auto_tracking` (`boolean`)

Enables sr_plan to normalize and register queries executed using the `EXPLAIN` command automatically. The default value is `off`. Only superusers can change this setting.

`sr_plan.max_local_cache_size` (`integer`)

Sets the maximum size of local cache, in kB. The default value is zero, which means no limit. Only superusers can change this setting.

`sr_plan.wal_rw` (`boolean`)

Enables physical replication of sr_plan data. When set to `off` on the primary, no data is transferred from it to a standby. When set to `off` on a standby, any data transferred from the primary is ignored. The default value is `off`.This parameter can only be set at server start.

`sr_plan.auto_capturing` (`boolean`)

Enables the automatic query capture in sr_plan. Setting this configuration parameter to `on` allows you to see the queries with constants in the text form as well as parameterized queries in the sr_captured_queries view. Information about executed queries is stored until the server restart. The default value is `off`. Only superusers can change this setting.

`sr_plan.max_captured_items` (`integer`)

Sets the maximum number of queries sr_plan can capture. The default value is 1000. This parameter can only be set at server start.

`sr_plan.sandbox` (`boolean`)

Enables reserving a separate area in shared memory to be used by a primary or standby node, which allows testing and analyzing queries with the existing data set without affecting the node operation. If set to `on` on the standby, sr_plan freezes plans only on this node and stores them in the “sandbox”, an alternative plan storage. If enabled on the primary, the extension uses the separate shared memory area that is not replicated to the standby. Changing the parameter value resets the sr_plan cache. The default value is `off`. Only superusers can change this setting.

G.8. utl_http — access data on the Internet over the HTTP protocol

utl_http is a Postgres Pro extension that allows accessing data on the Internet over the HTTP protocol (HTTP/1.0 and HTTP/1.1) by invoking HTTP callouts from SQL and PL/pgSQL. The functionality provided by this module overlaps substantially with the functionality of Oracle's `UTL_HTTP` package. With utl_http, you can write programs that communicate with HTTP servers. utl_http also contains functions that can be used in SQL queries. The extension supports HTTP over SSL, also known as HTTPS. The supported methods are `GET`, `POST PUT`, `UPLOAD`, `PATCH`, `HEAD`, `OPTIONS`, `DELETE`, `TRACE` (see *https://datatracker.ietf.org/doc/html/rfc9110#name-methods*), as well as any custom HTTP-methods.

utl_http is typically used as follows:

1. A request is created by `begin_request`.
2. Request parameters are set, for more information see Section G.8.3.3.
3. The response is processed by `get_response`.
4. The obtained response is manipulated using procedures from Section G.8.3.4.

G.8.1. Installation

The `utl_http` extension is provided with Postgres Pro Enterprise in a separate pre-built package `pg-pro-orautl-ent-16` (for the detailed installation instructions, see Chapter 17). To enable `utl_http`, create the extension using the following query:

```
CREATE EXTENSION utl_http;
```

G.8.2. Data Types

The utl_http extension provides several data types:

- `req` represents an HTTP request.

```
CREATE TYPE req AS (
   url          varchar(32767),
   method       varchar(64),
   http_version  varchar(64)
);
```

Table G.96. `req` Parameters

Parameter	Description
`url`	The URL of the HTTP request. It is set after the request is created by `begin_request` .
`method`	The method to be performed on the resource identified by the URL. It is set after the request is created by `begin_request`
`http_version`	The HTTP protocol version used to send the request. It is set after the request is created by `begin_request` .

- `resp` represents an HTTP response.

```
CREATE TYPE resp AS (
   status_code  integer,
   reason_phrase varchar(256),
   http_version  varchar(64)
);
```

Table G.97. `resp` Parameters

Parameter	Description
`status_code`	The status code returned by the web server. It is a 3-digit integer that indicates the results of the HTTP request as handled by the web server. It is set after the response is processed by `get_response`.
`reason_phrase`	The short textual message returned by the web server that describes the status code. It gives a brief description of the results of the HTTP request as handled by the web server. It is set after the response is processed by `get_response` .
`http_version`	The HTTP protocol version used in the HTTP response. It is set after the response is processed by `get_response` .

- The `cookie` type represents an HTTP cookie. The `cookie_table` type represents a collection of HTTP cookies. It is essentially an array data type created on the basis of the array created automatically.

```
CREATE TYPE cookie AS (
   name  varchar(256),
   value varchar(1024),
   domain varchar(256),
   expire timestamp with time zone,
   path  varchar(1024),
   secure bool,
   version int,
   comment varchar(1024)
);

CREATE DOMAIN cookie_table AS _cookie;
```

Table G.98. Fields of `cookie` and `cookie_table`

Parameter	Description
`name`	The name of the HTTP cookie.
`value`	The value of the cookie.
`domain`	The domain for which the cookie is valid.
`expire`	The time by which the cookie will expire.
`path`	The subset of URLs to which the cookie applies.
`secure`	Should the cookie be returned to the web server using secured means only.
`version`	The version of the HTTP cookie specification the cookie conforms.
`comment`	The comment that describes the intended use of the cookie.

- The `request_context_key` type is used to define the key to a request context. In Postgres Pro, it is represented by `integer` and preserved for the reasons of compatibility when migrating from Oracle.

G.8.3. utl_http Functions and Procedures

Note that the *`request_context`* in functions and procedures below is preserved for the reasons of compatibility when migrating from Oracle, and does not affect the result.

G.8.3.1. Simple HTTP Fetches

`request_function` and `request_pieces_function` take a string URL, contact that site, and return the data (typically HTML) obtained from that site.

`request(`*`url`* `text, `*`proxy`* `text default null) returns text`

Fetches a web page. This function returns the first 2000 bytes of the page at most.

`request_pieces(`*`url`* `text, `*`max_pieces`* `int default 32767, `*`proxy`* `text default null) returns text`

This function returns a PL/pgSQL table of 2000-byte pieces of the data retrieved from the given URL. The elements of the table returned by `request_pieces` are successive pieces of the data obtained from the HTTP request to that URL.

G.8.3.2. Session Settings

utl_http provides functions and procedures to manipulate the configuration and default behavior when HTTP requests are executed within a database user session. When a request is created, it inherits the

default settings of the HTTP cookie support, follow-redirect, body character set, and transfer timeout of the current session. When a response is created for a request, it inherits those settings from the request.

`set_response_error_check(enable bool default false)`

This procedure sets whether or not `get_response` raises an exception when the web server returns a status code that indicates an error — a status code in the 4xx or 5xx range.

`get_response_error_check(enable bool)`

This procedure checks if the response error check is set or not.

`set_transfer_timeout(timeout int4 default 60)`

This procedure sets the default timeout value for all future HTTP requests that utl_http should attempt while reading the HTTP response from the web server or proxy server. This timeout value may be used to avoid the programs from being blocked by busy web servers or heavy network traffic while retrieving web pages from the web servers. The default value of the timeout is 60 seconds.

`get_transfer_timeout(timeout int4)`

This procedure retrieves the default timeout value for all future HTTP requests.

`set_detailed_excp_support(enable bool default false)`

This procedure sets whether utl_http raises a detailed exception. By default, it raises the `REQUEST_FAILED` exception when an HTTP request fails. Use `get_detailed_sqlcode` and `get_detailed_sqlerrm` for more detailed information about the error.

The available exceptions are listed in Table G.99.

Table G.99. utl_http Exceptions

Exception	Error Code	Reason	Where Raised
`BAD_ARGUMENT`	29265	The argument passed to the interface is bad	Any HTTP request or response interface when detailed exception is enabled
`HEADER_NOT_FOUND`	29261	The header is not found	`get_header` , `get_header_by_name` when detailed exception is enabled
`END_OF_BODY`	29266	The end of HTTP response body is reached	`read_raw` , `read_text` , and `read_line` when detailed exception is enabled
`HTTP_CLIENT_ERROR`	29268	From `get_response` the response status code indicates that a client error has occurred (status code in 4xx range). From `begin_request` the HTTP proxy returns a status code in the 4xx range when making an HTTPS request through the proxy.	`get_response` , `begin_request` when detailed exception is enabled
`HTTP_SERVER_ERROR`	29269	From `get_response` the response status	`get_response` , `begin_request` when de-

Exception	Error Code	Reason	Where Raised
		code indicates that a server error has occurred (status code in 5xx range). From begin_request the HTTP proxy returns a status code in the 5xx range when making an HTTPS request through the proxy.	tailed exception is enabled
REQUEST_FAILED	29273	The request fails to execute	Any HTTP request or response interface when detailed exception is disabled

`get_detailed_excp_support(`*`enable`* `bool)`

This procedure checks if utl_http will raise a detailed exception or not.

G.8.3.3. HTTP Requests

utl_http provides functions and procedures to begin an HTTP request, manipulate attributes, and send the request information to the web server. When a request is created, it inherits the default settings of the HTTP cookie support, follow-redirect, body character set, and transfer timeout of the current session. The settings can be changed by calling the request interface.

`begin_request(`*`url`* `text,` *`method`* `text default 'GET',` *`http_version`* `text default null,` *`request_context`* `request_context_key default null) returns req`

This function begins a new HTTP request.

`set_header(`*`r`* `req,` *`name`* `text,` *`value`* `text)`

This procedure sets the HTTP request header for the future request.

`set_authentication(`*`r`* `req,` *`username`* `text,` *`password`* `text,` *`scheme`* `text default 'Basic',` *`for_proxy`* `boolean default false)`

This procedure sets HTTP authentication information in the HTTP request header. The web server needs this information to authorize the request.

`set_body_charset(`*`r`* `req,` *`charset`* `name default null)`

This procedure sets the character set when the media type is `text` but the character set is not specified in the `Content-Type` header and may take one of the following forms:

- Sets the default character set of the body of all future HTTP requests.

```
set_body_charset(
  charset    IN name DEFAULT NULL)
```

- Sets the character set of the request body.

```
set_body_charset(
 r     INOUT req,
  charset    IN name DEFAULT NULL)
```

`set_cookie_support(`*`r`* `req,` *`enable`* `bool)`

This procedure determines cookie support and may take one of the following forms:

- Enables or disables support for the HTTP cookies in the request.

```
set_cookie_support(
 r   INOUT req,
 enable  IN  bool DEFAULT true)
```

- Sets whether future HTTP requests will support HTTP cookies, and the maximum number of cookies maintained in the current database user session.

```
set_cookie_support(
 enable     IN bool,
 max_cookies    IN int4 DEFAULT 300,
 max_cookies_per_site IN int4 DEFAULT 20)
```

`set_follow_redirect(r req, max_redirects int4 default 3)`

This procedure sets the maximum number of times utl_http should follow HTTP redirect instruction in the HTTP responses to requests in `get_response`. Default is 3.

`set_proxy(proxy text, no_proxy_domains text)`

This procedure sets the proxy to be used for requests of HTTP or other protocols.

`write_raw(r req, data bytea)`

This procedure writes binary data in the HTTP request body for the future request.

`write_text(r req, data text)`

This procedure writes text data in the HTTP request body for the future request.

`end_request(r req)`

This procedure ends the HTTP request by resetting request parameters.

G.8.3.4. HTTP Responses

utl_http provides functions and procedures to manipulate an HTTP response obtained from `get_response` and receive response information from the web server. When a response is created for a request, it inherits settings of the HTTP cookie support, follow-redirect, body character set, and transfer timeout from the request. Only the body character set can be changed by calling the response interface.

`end_response(r resp)`

This procedure ends the HTTP response by resetting request parameters.

`get_authentication(r resp, scheme text, realm text, for_proxy bool default false)`

This procedure retrieves the HTTP authentication information needed for the request to be accepted by the web server as indicated in the HTTP response header.

`get_header(r resp, n int4, name text, value text)`

This procedure returns the n-th HTTP response header name and value returned in the response.

`get_header_by_name(r resp, name text, value text, n int4 default 1)`

This procedure returns the HTTP response header value returned in the response given the name of the header.

`get_header_count(r resp) returns int4`

This function returns the number of HTTP response headers returned in the response.

`get_response(r req, return_info_response bool default false) returns resp`

This function completes the HTTP request and response: reads the HTTP response and processes the status line and response headers. The status code, reason phrase and the HTTP protocol version are stored in the response record.

`read_raw(r resp, data bytea, len int4 default null)`

This procedure reads the HTTP response body in binary form and returns the output in the caller-supplied buffer.

`read_line(r resp, data text, remove_crlf bool default false)`

This procedure reads the HTTP response body in text form until the end of line is reached and returns the output in the caller-supplied buffer.

`read_text(r resp, data text, len int4 default null)`

This procedure reads the HTTP response body in text form and returns the output in the caller-supplied buffer.

G.8.3.5. HTTP Cookies

utl_http provides functions and procedures to manipulate HTTP cookies.

`add_cookies(cookies cookie_table, request_context request_context_key default null)`

This procedure adds the cookies maintained by utl_http.

`clear_cookies(request_context request_context_key default null)`

This procedure clears all the cookies currently maintained by utl_http.

`get_cookie_count(request_context request_context_key default null) returns int4`

This function returns the number of cookies currently maintained by utl_http set by all web servers.

`get_cookies(cookies cookie_table, request_context request_context_key default null) returns cookie_table`

This function returns all the number of cookies currently maintained by utl_http set by all web servers.

G.8.3.6. Error Conditions

utl_http provides functions to retrieve error information.

`get_detailed_sqlcode() returns int4`

Retrieves the detailed `SQLCODE` of the last exception raised (see Table G.99).

`get_detailed_sqlerrm() returns text`

Retrieves the detailed `SQLERRM` of the last exception raised (see Table G.99).

G.8.4. Example

```
DO $$
DECLARE
    request         utl_http.req;
    response        utl_http.resp;
    text_body       text;
BEGIN
    CALL utl_http.set_body_charset('WIN1251');

    request := utl_http.begin_request('https://postgrespro.ru/', 'GET');

    CALL utl_http.set_authentication(request, 'admin', 'qwerty', 'Basic', FALSE);

    response := utl_http.get_response(request);

    CALL utl_http.read_text(response, text_body);
```

```
    text_body = substring(text_body FROM 720 FOR 245);

    RAISE NOTICE '%', text_body;
END$$;
```

You can specify the `utl_http` schema in the `search_path` parameter explicitly to omit it in the body of a request:

```
SET search_path =utl_http, public;
```

The example above will then look as follows:

```
DO $$
DECLARE
    request         req;
    response        resp;
    text_body       text;
BEGIN
    CALL set_body_charset('WIN1251');

    request := begin_request('https://postgrespro.ru/docs/enterprise/17/utl-http',
 'GET');

    CALL set_authentication(request, 'admin', 'qwerty', 'Basic', FALSE);

    response := get_response(request);

    CALL read_text(response, text_body);

    text_body = substring(text_body FROM 720 FOR 245);

    RAISE NOTICE '%', text_body;
END$$;
```

G.9. utl_mail — manage emails

utl_mail is a Postgres Pro extension designed for managing emails, which includes commonly used email features, such as attachments, CC, and BCC. The functionality provided by this module overlaps substantially with the functionality of Oracle's `UTL_MAIL` package but larger amount of data can be sent as in Postgres Pro the `text` type is used for sending data, which can store up to 1GB.

G.9.1. Installation

The `utl_mail` extension is provided with Postgres Pro Enterprise in a separate pre-built package `pg-pro-orautl-ent-16` (for the detailed installation instructions, see Chapter 17). To enable `utl_mail`, create the extension using the following query:

```
CREATE EXTENSION utl_mail;
```

G.9.2. utl_mail Functions

utl_mail provides functions for email management. Note that some of the parameters within functions below, namely *host*, *port*, *timeout*, *username*, and *password*, are required to establish connection with the SMTP server and authentication.

`send(`*host* `text, `*port* `int, `*timeout* `int, `*username* `text, `*password* `text, `*sender* `text, `*recipients* `text, `*message* `text, `*cc* `text default null, `*bcc* `text default null, `*subject* `text default null, `*mime_type* `text default 'text/plain; charset=UTF-8', `*priority* `int default 3, `*replyto* `text default null, `*starttls* `bool default true)`

Packages an email into the appropriate format and sends the email to the specified SMTP server.

send_attach_bytea(*host* text, *port* int, *timeout* int, *username* text, *password* text, *sender* text, *recipients* text, *attachment* bytea, *message* text, *cc* text default null, *bcc* text default null, *subject* text default null, *mime_type* text default 'text/plain; charset=UTF-8', *priority* int default 3, *att_inline* bool default true, *att_mime_type* text default 'application/octet-stream', *att_filename* text default null, *replyto* text default null, *starttls* bool default true)

Packages an email containing a bytea attachment into the appropriate format and sends the email to the specified SMTP server.

The *attachment* specifies the bytea attachment. The *att_inline* specifies whether the attachment is viewable within the email body, default is true. The *att_mime_type* is the mime type of the attachment, default is application/octet. The *att_filename* is the string specifying the filename of the attachment, default is null.

send_attach_text(*host* text, *port* int, *timeout* int, *username* text, *password* text, *sender* text, *recipients* text, *attachment* text, *message* text, *cc* text default null, *bcc* text default null, *subject* text default null, *mime_type* text default 'text/plain; charset=UTF-8', *priority* int default 3, *att_inline* bool default true, *att_mime_type* text default 'text/plain; charset=UTF-8', *att_filename* text default null, *replyto* text default null, *starttls* bool default true)

Packages an email containing a text attachment into the appropriate format and sends the email to the specified SMTP server.

The *attachment* specifies the text attachment. The *att_inline* specifies whether the attachment is viewable within the email body, default is true. The *att_mime_type* is the mime type of the attachment, default is application/octet. The *att_filename* is the string specifying the filename of the attachment, default is null.

G.9.3. Example

The following example demonstrates sending an email with an attachment using utl_mail.

```
CREATE TABLE pictures (pic bytea);
INSERT INTO pictures (pic) values (pg_read_binary_file('/home/postgres/slon.jpg'));
DO $$
DECLARE
picture bytea;
BEGIN
SELECT * INTO picture FROM pictures LIMIT 1;
CALL utl_mail.send_attach_bytea
          (
            host => 'smtp.example.com',
            port => 25,
            timeout => 10,
            username => 'username@example.com',
            password => <password>,
            sender => 'Sender <sender@example.com>',
            recipients => 'Recipient <recipient@example.com>',
            message => 'Letter from pgpro_utl_mail!',
            attachment => picture,
            subject => 'utl_mail letter with picture',
            att_filename => 'slon.jpg',
            priority => 1
          );
END$$;
```

G.10. utl_smtp — send emails over SMTP

utl_smtp is a Postgres Pro extension designed for sending emails over SMTP from PL/pgSQL. The functionality provided by this module overlaps substantially with the functionality of Oracle's `UTL_SMTP` package.

G.10.1. Installation

The `utl_smtp` extension is provided with Postgres Pro Enterprise in a separate pre-built package `pgpro-orautl-ent-16` (for the detailed installation instructions, see Chapter 17). To enable `utl_smtp`, create the extension using the following query:

```
CREATE EXTENSION utl_smtp;
```

G.10.2. Usage

To send an email using utl_smtp, the functions must be called in a specific order:

- First, open connection by calling the `open_connection` function.
- Then send `HELO`/`EHLO` command to the SMTP server using `helo`/ `ehlo` respectively.
- Send sender and recipient addresses using `mail` and `rcpt` functions.
- Call the `open_data` function to start data sending process by sending the `DATA` command to the SMTP server.
- After that, `write_data` and `write_raw_data` can be called repeatedly to send the actual data.
- The data sending process is terminated by calling `close_data`.
- Once `open_data` is called, the only functions that can be called are `write_data`, `write_raw_data`, or `close_data`. Other calls result in an error being raised.
- Alternatively, data sending process can be streamlined with one call of `data`.
- After calling `close_data` or `data`, the email is sent — call `quit` to end the connection.

G.10.3. Data Types

The utl_smtp extension provides the following data types:

- The `reply` type is used to represent an SMTP reply line. Each SMTP reply line consists of a reply code followed by a text message. While a single reply line is expected for most SMTP commands, some SMTP commands expect multiple reply lines.

  Table G.100. `reply` Parameters

Parameter	Description
`code`	3-digit reply code
`text`	Text message of the reply

- The `connection` type represents an SMTP connection.

  Table G.101. `connection` Parameters

Parameter	Description
`host`	Name or IP address of the remote host when connection is established.
`port`	Port number of the remote SMTP server connected.
`tx_timeout`	Time in seconds that utl_smtp waits before timing out in a read or write operation in this connection. The timeout of server connection is always 60 seconds and cannot be configured.

Parameter	Description
private_socket	This parameter is used internally by Postgres Pro and should not be modified manually.

G.10.4. utl_smtp Functions

utl_smtp provides functions for sending emails over SMTP. Note that the functions that are supposed to return multiple reply lines return the `reply` array.

`auth(c connection, username text, password text, schemes text default 'PLAIN') returns reply`

Sends the `AUTH` command to authenticate to the SMTP server. Currently only the `PLAIN` authentication scheme is supported.

`close_all_connections() returns void`

Closes all SMTP connections and releases all associated resources.

`close_connection(c connection) returns void`

Closes the specified SMTP connection. This function can be called when sending data to the server before `close_data`. In this case, the next call to a function with this connection will raise an exception.

`close_data(c connection) returns reply`

Ends the e-mail message by sending the sequence `<CR><LF>.<CR><LF>` (a single period at the beginning of the line).

`command(c connection, cmd text, arg text default null) returns reply`

Sends an arbitrary SMTP command and can return a single reply line.

`command_replies(c connection, cmd text, arg text default null) returns reply[]`

Sends an arbitrary SMTP command and can return multiple reply lines.

`data(c connection, body text) returns reply`

Specifies the body of an email. It is essentially a sequence of calls: `open_data`, `write_data`, and `close_data`.

`ehlo(c connection, domain text) returns reply`

Performs the initial handshake with SMTP server using the `EHLO` command. The server returns a part of its configuration.

`helo(c connection, domain text) returns reply`

Performs the initial handshake with SMTP server using the `HELO` command.

`help(c connection, command text default null) returns reply`

Sends the `HELP` command. This command might not be implemented on all SMTP servers.

`last_reply(c connection) returns reply`

Returns the last reply of the SMTP server.

`mail(c connection, sender text, parameters text default null) returns reply`

Initiates an email transaction with the server by sending the `MAIL` command with the sender address.

`noop(c connection) returns reply`

Issues the `NOOP` command. This function is mainly used to check the connection.

`open_connection(host text, port int default 25, tx_timeout int default null, secure_connection_before_smtp bool default false, verify_peer bool default true) returns connection`

Opens a connection to an SMTP server. The *secure_connection_before_smtp* parameter specifies if the TLS connection is established before the SMTP connection (essentially, if this parameter is true, the connection will be using SMTPS instead of SMTP). The *verify_peer* parameter specifies if the certificates are validated when establishing the TLS connection.

`open_data(c connection) returns reply`

Sends the `DATA` command after which you can use `write_data` and `write_raw_data` to write a portion of the email.

`quit(c connection) returns reply`

Terminates an SMTP session and disconnects from the server.

`rcpt(c connection, recipient text, parameters text default null) returns reply`

Specifies the recipient of an email. The message transaction must have been started by a prior call to `MAIL`, and the connection to the mail server must have been opened and initialized by prior calls to `open_connection` and `helo` or `ehlo` respectively.

`rset(c connection) returns reply`

Terminates the current mail transaction. The client can call `rset` at any time after the connection to the SMTP server has been opened by means of `open_connection` until `data` or `open_data` is called.

`set_reply_error_check(c connection, enable bool) returns void`

Determines function behavior. If the *enable* parameter is set to true, which is the default, any error on the SMTP server raises an exception. If it is set to false, the user is responsible for analyzing the results returned by the functions to determine the error.

`starttls(c connection, verify_peer bool default true) returns reply`

Sends the `STARTTLS` command to secure the SMTP connection using TLS.

`vrfy(c connection, recipient text) returns reply`

Sends the `VRFY` command to verify the validity of the destination email. This command might not be implemented on all SMTP servers, and it may not return the correct information so it is not recommended to use it.

`write_data(c connection, data text) returns void`

Sends a portion of the text of the message, including headers, to the SMTP server. A repeated call to `write_data` appends data to the message.

`write_raw_data(c connection, data text) returns void`

Sends a portion of the text of the message, including headers, to the SMTP server. A repeated call to `write_data` appends data to the message. The same as `write_data`.

G.10.5. Examples

The following example demonstrates sending an email without attachment using utl_smtp.

```
DO $$
DECLARE
    conn utl_smtp.connection;
BEGIN
    conn := utl_smtp.open_connection('smtp.mail.ru', 25, 10);
    perform utl_smtp.ehlo(conn, 'localhost');
```

```
    perform utl_smtp.starttls(conn);
    perform utl_smtp.ehlo(conn, 'localhost');
    perform utl_smtp.auth(conn, 'test_email@example.com', 'super-secret-password');
    perform utl_smtp.mail(conn, 'sender@example.com');
    perform utl_smtp.rcpt(conn, 'recipient@example.com');
    perform utl_smtp.open_data(conn);
    perform utl_smtp.write_data(conn, E'Content-Type: multipart/mixed;
 boundary=------------------------6f48b7d5ded0c5fc\n');
    perform utl_smtp.write_data(conn, E'Mime-Version: 1.0\n');
    perform utl_smtp.write_data(conn, E'From: Sender <sender@example.com>\n');
    perform utl_smtp.write_data(conn, E'To: Recipient <recipient@example.com>\n');
    perform utl_smtp.write_data(conn, E'Subject: mail from utl_smtp\n');
    perform utl_smtp.write_data(conn, E'--------------------------6f48b7d5ded0c5fc\n');
    perform utl_smtp.write_data(conn, E'Content-Type: text/plain; charset=
\"UTF-8\"\n');
    perform utl_smtp.write_data(conn, E'Content-Transfer-Encoding: 8bit\n\n');
    perform utl_smtp.write_data(conn, E'This is body from inside Postgres Pro\n');
    perform utl_smtp.write_data(conn, E'Sent using utl_smtp\n');
    perform utl_smtp.write_data(conn, E'\n--------------------------6f48b7d5ded0c5fc--
\n');
    perform utl_smtp.close_data(conn);
    perform utl_smtp.quit(conn);
END$$;
```

The following example demonstrates exception handling with utl_smtp.

```
DO $$
DECLARE
    ...
    r utl_smtp.reply;
BEGIN
    ...
    some utl_smtp funcion calls
    ...
exception
    when others then
        r = utl_smtp.last_reply(conn);
        if r.code >= 500 then
            raise notice 'caught permanent error';
        elsif r.code >= 400 then
            raise notice 'caught transient error';
        else
            raise notice 'some other error';
        end if;
END$$;
```

Appendix H. Third-Party Modules and Extensions Shipped as Individual Packages

This appendix contains third-party modules and extensions that are made available in Postgres Pro Enterprise as individual packages. These packages are listed in Section 17.1.4.1, and the documentation for each module explains which package to choose to install it. Appendix F and Appendix G cover more modules and extensions included in the Postgres Pro Enterprise distribution. Note also the following extensions that are shipped as individual packages: orafce, pgvector, pldebugger, pljava, plpgsql_check, and plv8 (see Table 17.3 for details).

H.1. apache_age — graph database functionality

apache_age is a Postgres Pro extension that provides graph database functionality. AGE is an acronym for A Graph Extension. The goal of the project is to create single storage that can handle both relational and graph model data so that users can use standard ANSI SQL along with openCypher, the graph query language.

> **Important**
>
> User tables in apache_age databases contain columns using `reg*` OID-referencing system data types, therefore upgrading to a major version with pg_upgrade is not supported.

H.1.1. Installation and Setup

The `apache_age` extension is provided with Postgres Pro Enterprise as a separate pre-built package `apache-age-ent-16` (for the detailed installation instructions, see Chapter 17). Once you have Postgres Pro Enterprise installed, create the `apache_age` extension:

```
CREATE EXTENSION age;
```

For every connection of apache_age you start, load the apache_age library.

```
LOAD 'age';
```

Non-superusers must specify the full path to load the apache_age library.

```
LOAD '$libdir/plugins/age.so';
```

Add `ag_catalog` to the `search_path` to simplify queries:

```
SET search_path = ag_catalog, '$user', public;
```

In order to use apache_age, non-superusers need `USAGE` privileges on the `ag_catalog` schema (example for user `db_user`):

```
GRANT USAGE ON SCHEMA ag_catalog TO db_user;
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA ag_catalog TO db_user;
```

H.1.2. Graphs

A graph consists of a set of vertices and edges, where each individual node and edge possesses a map of properties. A vertex is the basic object of a graph, that can exist independently of everything else in the graph. An edge creates a directed connection between two vertices.

H.1.2.1. Create a Graph

To create a graph, use the `create_graph` function, located in the `ag_catalog` namespace.

```
create_graph(graph_name text) returns void
```

This function will not return any results. The graph is created if there is no error message. Tables needed to set up the graph are created automatically.

```
SELECT * FROM ag_catalog.create_graph('graph_name');
```

H.1.2.2. Grant Privileges

As a superuser, you can grant privilege on a specific existing graph to a non-superuser (example for graph `graph1` and user `db_user`):

```
GRANT USAGE ON SCHEMA graph1 TO db_user;
GRANT ALL PRIVILEGES ON SCHEMA graph1 TO db_user;
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA graph1 TO db_user;
GRANT ALL PRIVILEGES ON TABLE graph1._ag_label_vertex TO db_user;
```

H.1.2.3. Delete a Graph

To delete a graph, use the `drop_graph` function, located in the `ag_catalog` namespace.

```
drop_graph(graph_name text, cascade boolean) returns void
```

This function will not return any results. If there is no error message the graph has been deleted. It is recommended to set the *cascade* option to true, otherwise everything in the graph must be manually dropped with SQL DDL commands.

```
SELECT * FROM ag_catalog.drop_graph('graph_name', true);
```

H.1.2.4. How Graphs Are Stored In Postgres Pro

When creating graphs with apache_age, a Postgres Pro namespace will be generated for every individual graph. The name and namespace of the created graphs can be seen within the `ag_graph` table from the `ag_catalog` namespace:

```
SELECT create_graph('new_graph');

NOTICE:  graph 'new_graph' has been created
 create_graph
--------------

(1 row)

SELECT * FROM ag_catalog.ag_graph;

   name    | namespace
-----------+-----------
 new_graph | new_graph
(1 row)
```

After creating the graph, two tables are going to be created under the graph namespace to store vertices and edges: `_ag_label_vertex` and `_ag_label_edge`. These will be the parent tables of any new vertex or edge label. The query below shows how to retrieve the edge and vertex labels for all the graphs in the database.

```
-- Before creating a new vertex label.
SELECT * FROM ag_catalog.ag_label;

       name       | graph | id | kind |          relation          |        seq_name
------------------+-------+----+------+----------------------------
+-------------------------
```

```
 _ag_label_vertex | 68484 |  1 | v    | new_graph._ag_label_vertex |
 _ag_label_vertex_id_seq
 _ag_label_edge   | 68484 |  2 | e    | new_graph._ag_label_edge   |
 _ag_label_edge_id_seq
(2 rows)

-- Creating a new vertex label.
SELECT create_vlabel('new_graph', 'Person');
NOTICE:  VLabel 'Person' has been created
 create_vlabel
---------------

(1 row)

-- After creating a new vertex label.
SELECT * FROM ag_catalog.ag_label;
       name       | graph | id | kind |          relation          |        seq_name
------------------+-------+----+------+----------------------------
+-------------------------
 _ag_label_vertex | 68484 |  1 | v    | new_graph._ag_label_vertex |
 _ag_label_vertex_id_seq
 _ag_label_edge   | 68484 |  2 | e    | new_graph._ag_label_edge   |
 _ag_label_edge_id_seq
 Person           | 68484 |  3 | v    | new_graph.'Person'         | Person_id_seq
(3 rows)
```

Whenever a vertex label is created with the `create_vlabel()` function, a new table is generated within the `new_graph` namespace: `new_graph.'label'`. The same works for the `create_elabel()` function for the creation of edge labels. Creating vertices and edges with Cypher will automatically make these tables.

```
-- Creating two vertices and one edge.
SELECT * FROM cypher('new_graph', $$
CREATE (:Person {name: 'Daedalus'})-[:FATHER_OF]->(:Person {name: 'Icarus'})
$$) AS (a agtype);
 a
---
(0 rows)

-- Showing the newly created tables.
SELECT * FROM ag_catalog.ag_label;
       name       | graph | id | kind |          relation          |        seq_name
------------------+-------+----+------+----------------------------
+-------------------------
 _ag_label_vertex | 68484 |  1 | v    | new_graph._ag_label_vertex |
 _ag_label_vertex_id_seq
 _ag_label_edge   | 68484 |  2 | e    | new_graph._ag_label_edge   |
 _ag_label_edge_id_seq
 Person           | 68484 |  3 | v    | new_graph.'Person'         | Person_id_seq
 FATHER_OF        | 68484 |  4 | e    | new_graph.'FATHER_OF'      | FATHER_OF_id_seq
(4 rows)
```

Note

It is recommended that no DML or DDL commands are executed in the namespace that is reserved for the graph.

H.1.3. The apache_age Cypher Query Format

Cypher queries are constructed using a function called `cypher` in `ag_catalog`, which returns a Postgres Pro SETOF records.

`cypher(graph_name name, query_string cstring, parameters agtype) returns setof record`

Executes the Cypher query passed as an argument. If the Cypher query does not return results, a record definition still needs to be defined. The parameter map specified as *`parameters`* can only be used with prepared statements. An error will be thrown otherwise.

```
SELECT * FROM cypher('graph_name', $$
/* Cypher Query Here */
$$) AS (result1 agtype, result2 agtype);
```

H.1.3.1. Cypher in an Expression

Cypher may not be used as part of an expression, use a subquery instead. See Advanced Cypher Queries for information about how to use Cypher queries with expressions.

H.1.3.2. SELECT Clause

Calling Cypher in the `SELECT` clause as an independent column is not allowed. However, Cypher may be used when it belongs as a conditional.

```
SELECT
    cypher('graph_name', $$
         MATCH (v:Person)
         RETURN v.name
     $$);

ERROR:  cypher(...) in expressions is not supported
LINE 3:     cypher('graph_name', $$
            ^
HINT:  Use subquery instead if possible.
```

H.1.4. Data Types — Introduction to `agtype`

apache_age uses a custom data type called `agtype`, which is the only data type returned by apache_age. `agtype` is a superset of `json` and a custom implementation of `jsonb`.

H.1.4.1. Simple Data Types

H.1.4.1.1. Null

In Cypher, `null` is used to represent missing or undefined values. Conceptually, `null` means “a missing unknown value”, and it is treated differently from other values. For example, getting a property from a vertex that does not have said property produces `null`. Most expressions that take `null` as input will produce `null`. This includes boolean expressions that are used as predicates in the `WHERE` clause. In this case, anything that is not true is interpreted as being false. `null` is not equal to `null`. Not knowing two values does not imply that they are the same value. So the expression `null = null` yields `null` and not true.

The following query returns `null` as an empty space.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN NULL
$$) AS (null_result agtype);
```

```
 null_result
--------------

(1 row)
```

The concept of `NULL` in `agtype` and Postgres Pro is the same as it is in Cypher.

H.1.4.1.2. Integer

The `integer` type stores whole numbers, i.e. numbers without fractional components. Integer data type is a 64-bit field that stores values from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807. Attempts to store values outside this range will result in an error.

The type `integer` is the common choice, as it offers the best balance between range, storage size, and performance. The `smallint` type is generally used only if disk space is at a premium. The `bigint` type is designed to be used when the range of the integer type is insufficient.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN 1
$$) AS (int_result agtype);

 int_result
--------------
1
(1 row)
```

H.1.4.1.3. Float

The data type `float` is an inexact, variable-precision numeric type, conforming to the IEEE 754 Standard.

Inexact means that some values cannot be converted exactly to the internal format and are stored as approximations, so that storing and retrieving a value might show slight discrepancies. Managing these errors and how they propagate through calculations is the subject of an entire branch of mathematics and computer science and will not be discussed here, except for the following points:

- If you require exact storage and calculations (such as for monetary amounts), use the `numeric` type instead.
- If you want to do complicated calculations with these types for anything important, especially if you rely on certain behavior in boundary cases (infinity, underflow), you should evaluate the implementation carefully.
- Comparing two floating-point values for equality might not always work as expected.

Values that are too large or too small will cause an error. Rounding might take place if the precision of an input number is too high. Numbers too close to zero that are not representable as distinct from zero will cause an underflow error.

In addition to ordinary numeric values, the floating-point types have several special values:

- Infinity
- -Infinity
- NaN

These represent the IEEE 754 special values “infinity”, “negative infinity”, and “not-a-number”, respectively. When writing these values as constants in a Cypher command, you must put quotes around them and typecast them, for example:

```
SET x.float_value = '-Infinity'::float
```

On input, these strings are recognized in a case-insensitive manner.

> **Note**
>
> Note that IEEE 754 specifies that NaN should not compare equal to any other floating-point value (including NaN). However, in order to allow floats to be sorted correctly, apache_age evaluates `'NaN'::float = 'NaN'::float` to true. See Comparability and Equality for more details.

To use a float, denote a decimal value.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN 1.0
$$) AS (float_result agtype);

float_result
--------------
1.0
(1 row)
```

H.1.4.1.4. Numeric

The type `numeric` can store numbers with a very large number of digits. It is especially recommended for storing monetary amounts and other quantities where exactness is required. Calculations with `numeric` values yield exact results where possible, e.g., addition, subtraction, multiplication. However, calculations on `numeric` values are very slow compared to the integer types, or to the floating-point types.

We use the following terms below: The *precision* of a `numeric` is the total count of significant digits in the whole number, that is, the number of digits to both sides of the decimal point. The *scale* of a `numeric` is the count of decimal digits in the fractional part, to the right of the decimal point. So the number 23.5141 has a precision of 6 and a scale of 4. Integers can be considered to have a scale of zero.

Specifying `NUMERIC` without any precision or scale creates a column in which numeric values of any precision and scale can be stored, up to the implementation limit on precision. A column of this kind will not coerce input values to any particular scale, whereas `numeric` columns with a declared scale will coerce input values to that scale. (The SQL standard requires a default scale of 0, i.e., coercion to integer precision. We find this a bit useless. If you are concerned about portability, always specify the precision and scale explicitly.)

> **Note**
>
> The maximum allowed precision when explicitly specified in the type declaration is 1000; `NUMERIC` without a specified precision is subject to the limits described in Table 8.2.

If the scale of a value to be stored is greater than the declared scale of the column, the system will round the value to the specified number of fractional digits. Then, if the number of digits to the left of the decimal point exceeds the declared precision minus the declared scale, an error is raised.

Numeric values are physically stored without any extra leading or trailing zeroes. Thus, the declared precision and scale of a column are maximums, not fixed allocations. (In this sense the `numeric` type is more akin to `varchar(`*`n`*`)` than to `char(`*`n`*`)`.) The actual storage requirement is two bytes for each group of four decimal digits, plus three to eight bytes overhead.

In addition to ordinary numeric values, the `numeric` type allows the special value `NaN`, meaning “not-a-number”. Any operation on `NaN` yields another `NaN`. When writing this value as a constant in an SQL command, you must put quotes around it, for example `UPDATE table SET x = 'NaN'`. On input, the string `NaN` is recognized in a case-insensitive manner.

> **Note**
>
> In most implementations of the "not-a-number" concept, `NaN` is not considered equal to any other numeric value (including `NaN`). However, in order to allow floats to be sorted correctly, apache_age evaluates `'NaN'::numeric = 'NaN':numeric` to true. See Comparability and Equality for more details.

When rounding values, the `numeric` type rounds ties away from zero, while (on most machines) the `real` and `double precision` types round ties to the nearest even number.

When creating a `numeric` data type, the `::numeric` data annotation is required.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN 1.0::numeric
$$) AS (numeric_result agtype);

numeric_result
--------------
1.0::numeric
(1 row)
```

H.1.4.1.5. Bool

apache_age provides the standard Cypher type `boolean`. The `boolean` type can have several states: `true`, `false`, and a third state, `unknown`, which is represented by the `agtype` `null` value.

Boolean constants can be represented in Cypher queries by the keywords `TRUE`, `FALSE`, and `NULL`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN TRUE
$$) AS (boolean_result agtype);

boolean_result
--------------
true
(1 row)
```

Unlike Postgres Pro, in apache_age boolean outputs as the full word, i.e. `true` and `false` as opposed to `t` and `f`.

H.1.4.1.6. String

`agtype` string literals can contain the following escape sequences:

Table H.1. Escape Sequences

Escape Sequence	Character
\t	Tab
\b	Backspace
\n	Newline
\r	Carriage Return
\f	Form Feed
\'	Single Quote
\"	Double Quote

Escape Sequence	Character
\\	Backslash
\uXXXX	Unicode UTF-16 code point (4 hex digits must follow `\u`)

Use single (') quotes to identify a string. The output will use double (") quotes.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN 'This is a string'
$$) AS (string_result agtype);

string_result
--------------
"This is a string"
(1 row)
```

H.1.4.2. Composite Data Types

H.1.4.2.1. List

All examples will use the `WITH` clause and `RETURN` clause.

A literal list is created by using brackets and separating the elements in the list with commas.

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst
$$) AS (lst agtype);

                lst
-----------------------------------
 [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
(1 row)
```

A list can hold the value `null`, unlike when a `null` is an independent value, it will appear as the word `null` in a list.

```
SELECT *
FROM cypher('graph_name', $$
    WITH [null] as lst
    RETURN lst
$$) AS (lst agtype);

  lst
--------
 [null]
(1 row)
```

To access individual elements in the list, we use the square brackets again. This will extract from the start index and up to but not including the end index.

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[3]
$$) AS (element agtype);

 element
```

```
---------
 3
(1 row)
```

Map elements in lists:

```
SELECT *
FROM cypher('graph_name', $$
   WITH [0, {key: 'key_value'}, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst
$$) AS (map_value agtype);

                        map_value
-----------------------------------------------------
 [0, {"key": "key_value"}, 2, 3, 4, 5, 6, 7, 8, 9, 10]
(1 row)
```

Accessing map elements in lists:

```
SELECT *
FROM cypher('graph_name', $$
   WITH [0, {key: 'key_value'}, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[1].key
$$) AS (map_value agtype);

  map_value
-------------
 "key_value"
(1 row)
```

You can also use negative numbers, to start from the end of the list instead.

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[-3]
$$) AS (element agtype);

 element
---------
 8
(1 row)
```

Finally, you can use ranges inside the brackets to return ranges of the list.

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[0..3]
$$) AS (element agtype);

  element
-----------
 [0, 1, 2]
(1 row)
```

Negative index ranges:

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
```

```
    RETURN lst[0..-5]
$$) AS (lst agtype);

        lst
--------------------
 [0, 1, 2, 3, 4, 5]
(1 row)
```

Positive slices:

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[..4]
$$) AS (lst agtype);

     lst
--------------
 [0, 1, 2, 3]
(1 row)
```

Negative slices:

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[-5..]
$$) AS (lst agtype);

       lst
------------------
 [6, 7, 8, 9, 10]
(1 row)
```

Out-of-bound slices are simply truncated, but out-of-bound single elements return null.

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[15]
$$) AS (element agtype);

 element
---------

(1 row)
```

```
SELECT *
FROM cypher('graph_name', $$
    WITH [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] as lst
    RETURN lst[5..15]
$$) AS (element agtype);

       element
--------------------
 [5, 6, 7, 8, 9, 10]
(1 row)
```

H.1.4.2.2. Map

Maps can be constructed using Cypher.

You can construct a simple map with simple `agtype` values.

```
SELECT *
FROM cypher('graph_name', $$
    WITH {int_key: 1, float_key: 1.0, numeric_key: 1::numeric, bool_key: true,
 string_key: 'Value'} as m
    RETURN m
$$) AS (m agtype);

                                                    m
------------------------------------------------------------------------------------------
 {"int_key": 1, "bool_key": true, "float_key": 1.0, "string_key": "Value",
 "numeric_key": 1::numeric}
(1 row)
```

A map can also contain composite data types, i.e. lists and other maps.

```
SELECT *
FROM cypher('graph_name', $$
    WITH {listKey: [{inner: 'Map1'}, {inner: 'Map2'}], mapKey: {i: 0}} as m
    RETURN m
$$) AS (m agtype);

                                      m
---------------------------------------------------------------------
 {"mapKey": {"i": 0}, "listKey": [{"inner": "Map1"}, {"inner": "Map2"}]}
(1 row)
```

Property access of a map:

```
SELECT *
FROM cypher('graph_name', $$
    WITH {int_key: 1, float_key: 1.0, numeric_key: 1::numeric, bool_key: true,
 string_key: 'Value'} as m
    RETURN m.int_key
$$) AS (int_key agtype);

 int_key
---------
 1
(1 row)
```

Accessing list elements in maps:

```
SELECT *
FROM cypher('graph_name', $$
    WITH {listKey: [{inner: 'Map1'}, {inner: 'Map2'}], mapKey: {i: 0}} as m
    RETURN m.listKey[0]
$$) AS (m agtype);

         m
--------------------
 {"inner": "Map1"}
(1 row)
```

H.1.4.3. Simple Entities

An entity has a unique, comparable identity which defines whether or not two entities are equal.

An entity is assigned a set of properties, each of which are uniquely identified in the set by the irrespective property keys.

H.1.4.3.1. Graph ID

Simple entities are assigned a unique `graphid`. A `graphid` is a unique composition of the entity label id and a unique sequence assigned to each label. Note that there will be overlap in IDs when comparing entities from different graphs.

A label is an identifier that classifies vertices and edges into certain categories.

- Edges are required to have a label, but vertices do not.
- The names of labels between vertices and edges cannot overlap.

See `CREATE` clause for information about how to make entities with labels.

Both vertices and edges may have properties. Properties are attribute values, and each attribute name should be defined only as a string type.

H.1.4.4. Vertex

- A vertex is the basic entity of the graph, with the unique attribute of being able to exist in and of itself.
- A vertex may be assigned a label.
- A vertex may have zero or more outgoing edges.
- A vertex may have zero or more incoming edges.

Table H.2. Data Format

Attribute Name	Description
id	Graph ID for this vertex
label	Name of the label this vertex has
properties	Properties associated with this vertex

```
{id:1; label: 'label_name'; properties: {prop1: value1, prop2: value2}}::vertex
```

Type casting a map to a vertex:

```
SELECT *
FROM cypher('graph_name', $$
    WITH {id: 0, label: 'label_name', properties: {i: 0}}::vertex as v
    RETURN v
$$) AS (v agtype);

                                  v
-------------------------------------------------------------------
 {"id": 0, "label": "label_name", "properties": {"i": 0}}::vertex
(1 row)
```

H.1.4.5. Edge

An edge is an entity that encodes a directed connection between exactly two nodes, the source node and the target node. An outgoing edge is a directed relationship from the point of view of its source node. An incoming edge is a directed relationship from the point of view of its target node. An edge is assigned exactly one edge type.

Table H.3. Data Format

Attribute Name	Description
id	Graph ID for this edge
startid	Graph ID for the source node
endid	Graph ID for the target node

Attribute Name	Description
label	Name of the label this vertex has
properties	Properties associated with this vertex

```
{id: 3; startid: 1; endid: 2; label: 'edge_label' properties{prop1: value1, prop2:
 value2}}::edge
```

Type casting a map to an edge:

```
SELECT *
FROM cypher('graph_name', $$
    WITH {id: 2, start_id: 0, end_id: 1, label: 'label_name', properties: {i: 0}}::edge
 as e
    RETURN e
$$) AS (e agtype);

                                                e
-------------------------------------------------------------------------------------------
 {"id": 2, "label": "label_name", "end_id": 1, "start_id": 0, "properties": {"i":
 0}}::edge
(1 row)
```

H.1.4.6. Composite Entities

A path is a series of alternating vertices and edges. A path must start with a vertex, and have at least one edge.

Type casting a list to a path:

```
SELECT *
FROM cypher('graph_name', $$
    WITH [{id: 0, label: 'label_name_1', properties: {i: 0}}::vertex,
             {id: 2, start_id: 0, end_id: 1, label: 'edge_label', properties: {i:
 0}}::edge,
           {id: 1, label: 'label_name_2', properties: {}}::vertex
           ]::path as p
    RETURN p
$$) AS (p agtype);

                             p
-------------------------------------------------------------------------------------------
 [{"id": 0, "label": "label_name_1", "properties": {"i": 0}}::vertex, {"id": 2,
 "label": "edge_label", "end_id": 1, "start_id": 0, "properties": {"i": 0}}::edge,
 {"id": 1, "label": "label_name_2", "properties": {}}::vertex]::path
(1 row)
```

H.1.5. Comparability, Equality, Orderability and Equivalence

apache_age already has good semantics for equality within the primitive types (booleans, strings, integers, and floats) and maps. Furthermore, Cypher has good semantics for comparability and orderability for integers, floats, and strings, within each of the types. However, working with values of different types deviates from Postgres Pro defined logic and the openCypher specification:

- Comparability between values of different types is defined. This deviation is particularly pronounced when it occurs as part of the evaluation of predicates (in `WHERE`).
- `ORDER BY` will not fail if the values passed to it have different types.

The underlying conceptual model is complex and sometimes inconsistent. This leads to an unclear relationship between comparison operators, equality, grouping, and `ORDER BY`. Comparability and orderabil-

ity are aligned with each other consistently, as all types can be ordered and compared. The difference between equality and equivalence, as exposed by `IN`, `=`, `DISTINCT`, and grouping, in apache_age is limited to testing two instances of the value `null` to each other. In equality, `null = null` is `null`. In equivalence, used by `DISTINCT` and when grouping values, two null values are always treated as being the same value. However, equality treats `null` values differently if they are an element of a list or a map value.

H.1.5.1. Concepts

The openCypher specification features four distinct concepts related to equality and ordering:

- Comparability is used by the inequality operators (>, <, >=, <=) and defines the underlying semantics of how to compare two values.
- Equality is used by the equality operators (=, <>), and the list membership operator (`IN`). It defines the underlying semantics to determine if two values are the same in these contexts. Equality is also used implicitly by literal maps in node and relationship patterns, since such literal maps are merely a shorthand notation for equality predicates.
- Orderability is used by the `ORDER BY` clause, and defines the underlying semantics of how to order values.
- Equivalence is used by the `DISTINCT` modifier and by grouping in projection clauses (`WITH`, `RETURN`), and defines the underlying semantics to determine if two values are the same in these contexts.

H.1.5.2. Comparability and Equality

Comparison operators need to function as one would expect comparison operators to function — equality and comparability. But, at the same time, they need to allow the sorting of column data — equivalence and orderability.

Unfortunately, it may not be possible to implement separate comparison operators for equality and comparison operations, and, equivalence and orderability operations, in Postgres Pro, for the same query. So we prioritize equivalence and orderability over equality and comparability to allow for ordering of output data.

H.1.5.2.1. Comparability

Comparability is defined between any pair of values, as specified below.

- Numbers
  - Numbers of different types (excluding NaN values and the Infinities) are compared to each other as if both numbers would have been coerced to arbitrary precision `bigdecimal` (currently outside the Cypher type system) before comparing them with each other numerically in ascending order.
  - Comparison to any value that is not also number follows the rules of orderability.
  - Floats do not have the required precision to represent all of the whole numbers in the range of `agtype integer` and `agtype numeric`. When casting an `integer` or `agtype numeric` to a `float`, unexpected results can occur when casting values in the high and low range.
  - Integers
    - Integers are compared numerically in ascending order.
  - Floats
    - Floats (excluding NaN values and the Infinities) are compared numerically in ascending order.
    - Positive infinity is of type `FLOAT`, equal to itself and greater than any other number, except NaN values.
    - Negative infinity is of type `FLOAT`, equal to itself and less than any other number.
    - NaN values are comparable to each and greater than any other float value.
  - Numeric
    - Numerics are compared numerically in ascending order.
- Booleans

  - Booleans are compared such that false is less than true.
  - Comparison to any value that is not also a boolean follows the rules of orderability.
- Strings
  - Strings are compared in dictionary order, i.e. characters are compared pairwise in ascending order from the start of the string to the end. Characters missing in a shorter string are considered to be less than any other character. For example, `'a' < 'aa'`.
  - Comparison to any value that is not also a string follows the rules of orderability.
- Lists
  - Lists are compared in sequential order, i.e. list elements are compared pairwise in ascending order from the start of the list to the end. Elements missing in a shorter list are considered to be less than any other value (including `null` values), for example, `[1] < [1, 0]` but also `[1] < [1, null]`.
  - Comparison to any value that is not also a list follows the rules of orderability.
- Maps
  - The comparison order for maps is unspecified and left to implementations.
  - The comparison order for maps must align with the equality semantics outlined below. In consequence, any map that contains an entry that maps its key to a null value is incomparable. For example, `{a: 1} <= {a: 1, b: null}` evaluates to null.
  - Comparison to any value that is not also a regular map follows the rules of orderability.

Entities:

- Vertices: The comparison order for vertices is based on the assigned `graphid`.
- Edges: The comparison order for edges is based on the assigned `graphid`.
- Paths: Paths are compared as if they were a list of alternating nodes and relationships of the path from the start node to the end node. For example, given nodes `n1`, `n2`, `n3`, and relationships `r1` and `r2`, and given that `n1 < n2 < n3` and `r1 < r2`, then the path `p1` from `n1` to `n3` via `r1` would be less than the path `p2` to `n1` from `n2` via `r2`. Paths are expressed in terms of lists:

```
p1 < p2
<=> [n1, r1, n3] < [n1, r2, n2]
<=> n1 < n1 || (n1 = n1 && [r1, n3] < [r2, n2])
<=> false || (true && [r1, n3] < [r2, n2]) <=> [r1, n3] < [r2, n2]
<=> r1 < r2 || (r1 = r2 && n3 < n2)
<=> true || (false && false)
<=> true
```

> **Note**
>
> Comparison to any value that is not also a path will return false.

- NULL: `null` is incomparable with any other value (including other `null` values.)

H.1.5.3. Orderability Between Different `agtype` Types

The ordering of different `agtype` types, when using <, <=, >, >= from the smallest value to the largest value is:

1. Path
2. Edge
3. Vertex
4. Object
5. Array
6. String
7. Bool

8. Numeric, Integer, Float
9. NULL

> **Note**
>
> This is subject to change in future releases.

H.1.6. Operators

H.1.6.1. String Specific Comparison Operators

```
SELECT * FROM cypher('graph_name', $$
CREATE (:Person {name: 'John'}),
       (:Person {name: 'Jeff'}),
       (:Person {name: 'Joan'}),
       (:Person {name: 'Bill'})
$$) AS (result agtype);
```

Starts With

Performs case-sensitive prefix searching on strings.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name STARTS WITH "J"
 RETURN v.name
$$) AS (names agtype);

 names
--------
 "John"
 "Jeff"
 "Joan"
(3 rows)
```

Contains

Performs case-sensitive inclusion searching in strings.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name CONTAINS "o"
 RETURN v.name
$$) AS (names agtype);

 names
--------
 "John"
 "Joan"
(2 rows)
```

Ends With

Performs case-sensitive suffix searching on strings.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name ENDS WITH "n"
 RETURN v.name
$$) AS (names agtype);
```

```
 names
--------
 "John"
 "Joan"
(2 rows)
```

H.1.6.1.1. Regular Expressions

apache_age supports the use of POSIX regular expressions using the =~ operator. By default =~ is case sensitve.

Basic String Matching

The =~ operator when no special characters are given, act like the = operator.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name =~ 'John'
 RETURN v.name
$$) AS (names agtype);

 names
--------
 "John"
(1 row)
```

Case-Insensitive Search

Adding `(?i)` at the beginning of the string will make the comparison case insensitive.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name =~ '(?i)JoHn'
 RETURN v.name
$$) AS (names agtype);

 names
--------
 "John"
(1 row)
```

The . Wildcard

The . operator acts as a wildcard to match any single character.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name =~ 'Jo.n'
 RETURN v.name
$$) AS (names agtype);

 names
--------
 "John"
 "Joan"
(2 rows)
```

The * Wildcard

The * wildcard after a character will match to 0 or more of the previous character.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
```

```
 WHERE v.name =~ 'Johz*n'
 RETURN v.name
$$) AS (names agtype);

names
--------
 "John"
(1 row)
```

The + Operator

The + operator matches to 1 or more the previous character.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name =~ 'Bil+'
 RETURN v.name
$$) AS (names agtype);

 names
--------
 "Bill"
(1 row)
```

The . and * Wildcards Together

You can use the . and * wildcards together to represent the rest of the string.

```
SELECT * FROM cypher('graph_name', $$
 MATCH (v:Person)
 WHERE v.name =~ 'J.*'
 RETURN v.name
$$) AS (names agtype);

 names
--------
 "John"
 "Jeff"
 "Joan"
(3 rows)
```

H.1.6.2. Operator Precedence

Operator precedence in apache_age is shown below:

Table H.4. Operator Precedence

Precedence	Operator	Description
1	.	Property Access
2	[]	Map and List Subscripting
	()	Function Call
3	STARTS WITH	Case-sensitive prefix searching on strings
	ENDS WITH	Case-sensitive suffix searching on strings
	CONTAINS	Case-sensitive inclusion searching on strings
	=~	Regular expression string matching

Precedence	Operator	Description
4	-	Unary Minus
5	IN	Checking if an element exists in a list
	IS NULL	Checking a value is NULL
	IS NOT NULL	Checking a value is not NULL
6	^	Exponentiation
7	* / %	Multiplication, division and remainder
8	+ -	Addition and Subtraction
9	= <>	For relational = and ≠ respectively
	< <=	For relational < and ≤ respectively
	> >=	For relational > and ≥ respectively
10	NOT	Logical NOT
11	AND	Logical AND
12	OR	Logical OR

H.1.7. Aggregation

Generally an aggregation `aggr(expr)` processes all matching rows for each aggregation key found in an incoming record (keys are compared using equivalence).

In a regular aggregation (i.e. of the form `aggr(expr)`), the list of aggregated values is the list of candidate values with all `null` values removed from it.

```
SELECT * FROM cypher('graph_name', $$
    CREATE (a:Person {name: 'A', age: 13}),
    (b:Person {name: 'B', age: 33, eyes: "blue"}),
    (c:Person {name: 'C', age: 44, eyes: "blue"}),
    (d1:Person {name: 'D', eyes: "brown"}),
    (d2:Person {name: 'D'}),
    (a)-[:KNOWS]->(b),
    (a)-[:KNOWS]->(c),
    (a)-[:KNOWS]->(d1),
    (b)-[:KNOWS]->(d2),
    (c)-[:KNOWS]->(d2)
$$) as (a agtype);
```

H.1.7.1. Auto Group By

To calculate aggregated data, Cypher offers aggregation, analogous to SQL `GROUP BY`.

Aggregating functions take a set of values and calculate an aggregated value over them. Examples are `avg()` that calculates the average of multiple numeric values, or `min()` that finds the smallest numeric or string value in a set of values. When we say below that an aggregating function operates on a set of values, we mean these to be the result of the application of the inner expression (such as `n.age`) to all the records within the same aggregation group.

Aggregation can be computed over all the matching subgraphs, or it can be further divided by introducing grouping keys. These are non-aggregate expressions, that are used to group the values going into the aggregate functions.

Assume we have the following `RETURN` statement:

```
SELECT * FROM cypher('graph_name', $$
    MATCH (v:Person)
    RETURN v.name, count(*)
$$) as (grouping_key agtype, count agtype);

 grouping_key | count
--------------+-------
 "A"          | 1
 "D"          | 2
 "B"          | 1
 "C"          | 1
(4 rows)
```

We have two return expressions: `grouping_key`, and `count(*)`. The first, `grouping_key`, is not an aggregate function, and so it will be the grouping key. The latter, `count(*)` is an aggregate expression. The matching subgraphs will be divided into different buckets, depending on the grouping key. The aggregate function will then be run on these buckets, calculating an aggregate value per bucket.

H.1.7.2. Sorting on Aggregate Functions

To use aggregations to sort the result set, the aggregation must be included in the `RETURN` to be used in the `ORDER BY`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (me:Person)-[]->(friend:Person)
    RETURN count(friend), me
    ORDER BY count(friend)
$$) as (friends agtype, me agtype);
```

H.1.7.3. Distinct aggregation

In a distinct aggregation (i.e. of the form `aggr(DISTINCT expr)`), the list of aggregated values is the list of candidate values with all `null` values removed from it. Furthermore, in a distinct aggregation, only one of all equivalent candidate values is included in the list of aggregated values, i.e. duplicates under equivalence are removed.

The `DISTINCT` operator works in conjunction with aggregation. It is used to make all values unique before running them through an aggregate function.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (v:Person)
    RETURN count(DISTINCT v.eyes), count(v.eyes)
$$) as (distinct_eyes agtype, eyes agtype);

 distinct_eyes | eyes
---------------+------
 2             | 3
(1 row)
```

H.1.7.4. Ambiguous Grouping Statements

This feature of not requiring the user to specify their grouping keys for a query allows for ambiguity on what Cypher should qualify as their grouping keys.

```
SELECT * FROM cypher('graph_name', $$
CREATE (:L {a: 1, b: 2, c: 3}),
```

```
       (:L {a: 2, b: 3, c: 1}),
       (:L {a: 3, b: 1, c: 2})
$$) as (a agtype);
```

H.1.7.4.1. Invalid Query in apache_age

apache_age solution to this problem is to not allow a `WITH` or `RETURN` column to combine aggregate functions with variables that are not explicitly listed in another column of the same `WITH` or `RETURN` clause.

```
SELECT * FROM cypher('graph_name', $$
    MATCH (x:L)
    RETURN x.a + count(*) + x.b + count(*) + x.c
$$) as (a agtype);

ERROR:  'x' must be either part of an explicitly listed key or used inside an aggregate
 function
LINE 3: RETURN x.a + count(*) + x.b + count(*) + x.c
```

H.1.7.4.2. Valid Query in apache_age

Columns that do not include an aggregate function in apache_age are considered to be the grouping keys for that `WITH` or `RETURN` clause.

For the above query, the user could rewrite the query in several ways that will return results.

```
SELECT * FROM cypher('graph_name', $$
    MATCH (x:L)
    RETURN (x.a + x.b + x.c) + count(*) + count(*), x.a + x.b + x.c
$$) as (count agtype, key agtype);

count  | key
-------+-----
 12    | 6
(1 row)
```

`x.a + x.b + x.c` is the grouping key. Grouping keys created like this must include parenthesis.

```
SELECT * FROM cypher('graph_name', $$
    MATCH (x:L)
    RETURN x.a + count(*) + x.b + count(*) + x.c, x.a, x.b, x.c
$$) as (count agtype, a agtype, b agtype, c agtype);

 count | a | b | c
-------+---+---+---
 10    | 3 | 1 | 2
 10    | 2 | 3 | 1
 10    | 1 | 2 | 3
(3 rows)
```

`x.a`, `x.b`, and `x.c` will be considered different grouping keys.

H.1.7.4.3. Vertices and Edges in Ambiguous Grouping

Alternatively, the grouping key can be a vertex or edge, and then any properties of the vertex or edge can be specified without being explicitly stated in a `WITH` or `RETURN` column.

```
SELECT * FROM cypher('graph_name', $$
    MATCH (x:L)
    RETURN count(*) + count(*) + x.a + x.b + x.c, x
$$) as (count agtype, key agtype);

 count |                                              key
```

```
-------
+-------------------------------------------------------------------------------------
 8     | {"id": 1407374883553283, "label": "L", "properties": {"a": 3, "b": 1, "c":
 2}}::vertex
 8     | {"id": 1407374883553281, "label": "L", "properties": {"a": 1, "b": 2, "c":
 3}}::vertex
 8     | {"id": 1407374883553282, "label": "L", "properties": {"a": 2, "b": 3, "c":
 1}}::vertex
(3 rows)
```

Results will be grouped on `x`, because it is safe to assume that properties considered unnecessary for grouping are unambiguous.

H.1.7.4.4. Hiding Unwanted Grouping Keys

If the grouping key is considered unnecessary for the query output, the aggregation can be done in a `WITH` clause then passing information to the `RETURN` clause.

```
SELECT * FROM cypher('graph_name', $$
    MATCH (x:L)
    WITH count(*) + count(*) + x.a + x.b + x.c as column, x
    RETURN column
$$) as (a agtype);

 a
---
 8
 8
 8
(3 rows)
```

H.1.8. Importing Graph from Files

You can use the following instructions to create a graph from the files:

- Functions to load graphs from files
- Structure of CSV files that load functions as input
- Simple source code example to load countries and cities from the files

> **Note**
>
> User must create graph and labels before loading data from files.

H.1.8.1. Load Graph Functions

Following are the details about the functions to create vertices and edges from the file.

Function `load_labels_from_file` is used to load vertices from CSV files.

```
load_labels_from_file('graph_name',
                      'label_name',
                      'file_path')
```

By adding the fourth parameter user can exclude the `id` field. Use this when there is no `id` field in the file.

```
load_labels_from_file('graph_name',
                      'label_name',
                      'file_path',
                      false)
```

Function `load_edges_from_file` can be used to load edges from the CSV file. See the file structure below.

> **Note**
>
> Make sure that IDs in the edge file are identical to ones that are in vertices files.

```
load_edges_from_file('graph_name',
                     'label_name',
                     'file_path');
```

H.1.8.2. Explanation about the CSV format

Following is the explanation about the structure for CSV files for vertices and edges.

A CSV file for nodes is formatted as follows:

Table H.5. CSV File Format for Nodes

Field name	Field description
id	The first column of the file. All values are a positive integer. This is an optional field when `id_field_exists` is `false`. However, it should be present when `id_field_exists` is *not* set to false.
Properties	All other columns contain the properties for the nodes. Header row contains the name of property.

Similarly, a CSV file for edges is formatted as follows:

Table H.6. CSV File Format for Edges

Field name	Field description
start_id	Node ID of the node from where the edge is started. This ID is present in `nodes.csv` file.
start_vertex_type	Class of the node
end_id	End ID of the node at which the edge is terminated.
end_vertex_type	Class of the node
properties	Properties of the edge. The header contains the property name.

H.1.8.3. Example SQL Script

- Load apache_age and create a graph.

  ```
  LOAD 'age';

  SET search_path TO ag_catalog;
  SELECT create_graph('agload_test_graph');
  ```
- Create label `Country` and load vertices from the CSV file. Note that this CSV file has the `id` field.

  ```
  SELECT create_vlabel('agload_test_graph','Country');
  SELECT load_labels_from_file('agload_test_graph',
                               'Country',
                               '/age/regress/age_load/data/countries.csv');
  ```
- Create label `City` and load vertices from the CSV file. Note that this CSV file has the `id` field.

```
SELECT create_vlabel('agload_test_graph','City');
SELECT load_labels_from_file('agload_test_graph',
                             'City',
                             '/age/regress/age_load/data/cities.csv');
```

- Create label `has_city` and load edges from the CSV file.

```
SELECT create_elabel('agload_test_graph','has_city');
SELECT load_edges_from_file('agload_test_graph', 'has_city',
     '/age/regress/age_load/data/edges.csv');
```

- Check if the graph has been loaded properly.

```
SELECT table_catalog, table_schema, table_name, table_type
FROM information_schema.tables
WHERE table_schema = 'agload_test_graph';

SELECT COUNT(*) FROM agload_test_graph."Country";
SELECT COUNT(*) FROM agload_test_graph."City";
SELECT COUNT(*) FROM agload_test_graph."has_city";

SELECT COUNT(*) FROM cypher('agload_test_graph', $$MATCH(n) RETURN n$$) as (n
 agtype);
SELECT COUNT(*) FROM cypher('agload_test_graph', $$MATCH (a)-[e]->(b) RETURN e$$) as
 (n agtype);
```

H.1.8.3.1. Creating Vertices Without ID Field in the File

- Create label `Country2` and load vertices from the CSV file. Note that this CSV file has no `id` field.

```
SELECT create_vlabel('agload_test_graph','Country2');
SELECT load_labels_from_file('agload_test_graph',
                             'Country2',
                             '/age/regress/age_load/data/countries.csv',
                             false);
```

- Create label `City2` and load vertices from CSV file. Note this CSV file has no `id` field.

```
SELECT create_vlabel('agload_test_graph','City2');
SELECT load_labels_from_file('agload_test_graph',
                             'City2',
                             '/age/regress/age_load/data/cities.csv',
                             false);
```

- Check if the graph has been loaded properly and perform difference analysis between IDs created automatically and picked from the files.

  Labels `Country` and `City` were created with the `id` field in the file.

  Labels `Country2` and `City2` were created with no `id` field in the file.

```
SELECT COUNT(*) FROM agload_test_graph."Country2";
SELECT COUNT(*) FROM agload_test_graph."City2";

SELECT id FROM agload_test_graph."Country" LIMIT 10;
SELECT id FROM agload_test_graph."Country2" LIMIT 10;

SELECT * FROM cypher('agload_test_graph', $$MATCH(n:Country {iso2 : 'BE'})
    RETURN id(n), n.name, n.iso2 $$) as ('id(n)' agtype, 'n.name' agtype, 'n.iso2'
 agtype);
SELECT * FROM cypher('agload_test_graph', $$MATCH(n:Country2 {iso2 : 'BE'})
    RETURN id(n), n.name, n.iso2 $$) as ('id(n)' agtype, 'n.name' agtype, 'n.iso2'
 agtype);
```

```
SELECT * FROM cypher('agload_test_graph', $$MATCH(n:Country {iso2 : 'AT'})
    RETURN id(n), n.name, n.iso2 $$) as ('id(n)' agtype, 'n.name' agtype, 'n.iso2'
 agtype);
SELECT * FROM cypher('agload_test_graph', $$MATCH(n:Country2 {iso2 : 'AT'})
    RETURN id(n), n.name, n.iso2 $$) as ('id(n)' agtype, 'n.name' agtype, 'n.iso2'
 agtype);

SELECT drop_graph('agload_test_graph', true);
```

H.1.9. MATCH

The `MATCH` clause allows you to specify the patterns a query will search for in the database. This is the primary way of retrieving data for use in a query.

A `WHERE` clause often follows a `MATCH` clause to add user-defined restrictions to the matched patterns to manipulate the set of data returned. The predicates are part of the pattern description, and should not be considered a filter applied only after the matching is done. This means that `WHERE` should always be put together with the `MATCH` clause it belongs to.

`MATCH` can occur at the beginning of the query or later, possibly after a `WITH`. If it is the first clause, nothing will have been bound yet, and Cypher will design a search to find the results matching the clause and any associated predicates specified in any `WHERE` clause. Vertices and edges found by this search are available as bound pattern elements and can be used for pattern matching of sub-graphs. They can also be used in any future clauses where Cypher will use the known elements, and from there find further unknown elements.

Cypher is a declarative language, and so typically the query itself does not specify the algorithm to use to perform the search. Predicates in `WHERE` parts can be evaluated before pattern matching, during pattern matching, or after the match is found.

H.1.9.1. Basic Vertex Finding

H.1.9.1.1. Get All Vertices

By specifying a pattern with a single vertex and no labels, all vertices in the graph will be returned.

```
SELECT * FROM cypher('graph_name', $$
MATCH (v)
RETURN v
$$) as (v agtype);
```

```
                                        v
------------------------------------------------------------------------------
{id: 0; label: 'Person'; properties: {name: 'Charlie Sheen'}}::vertex
{id: 1; label: 'Person'; properties: {name: 'Martin Sheen'}}::vertex
{id: 2; label: 'Person'; properties: {name: 'Michael Douglas'}}::vertex
{id: 3; label: 'Person'; properties: {name: 'Oliver Stone'}}::vertex
{id: 4; label: 'Person'; properties: {name: 'Rob Reiner'}}::vertex
{id: 5; label: 'Movie'; properties: {name: 'Wall Street'}}::vertex
{id: 6; label: 'Movie'; properties: {title: 'The American President'}}::vertex
(7 rows)
```

Returns all vertices in the database.

H.1.9.1.2. Get All Vertices with a Label

Getting all vertices with a label is done with a single node pattern where the vertex has the label specified as follows:

```
SELECT * FROM cypher('graph_name', $$
```

```
MATCH (movie:Movie)
RETURN movie.title
$$) as (title agtype);

         title
-----------------------
'Wall Street'
'The American President'
(2 rows)
```

Returns all the movies in the database.

H.1.9.1.3. Related Vertices

The symbol `-[]-` specifies an edge, without specifying the type or direction of the edge.

```
SELECT * FROM cypher('graph_name', $$
MATCH (director {name: 'Oliver Stone'})-[]-(movie)
RETURN movie.title
$$) as (title agtype);

    title
-------------
'Wall Street'
(1 row)
```

Returns all the movies directed by “Oliver Stone”.

H.1.9.1.4. Match with Labels

To constrain your pattern with labels on vertices, add it to the vertex in the pattern, using the label syntax.

```
SELECT * FROM cypher('graph_name', $$
MATCH (:Person {name: 'Oliver Stone'})-[]-(movie:Movie)
RETURN movie.title
$$) as (title agtype);

    title
-------------
'Wall Street'
(1 row)
```

Returns any vertices connected with the `Person` “Oliver” that are labeled `Movie`.

H.1.9.2. Edge Basics

H.1.9.2.1. Outgoing Edges

To return directed edges, you may use `->` or `<-` to specify the direction of which the edge points.

```
SELECT * FROM cypher('graph_name', $$
MATCH (:Person {name: 'Oliver Stone'})-[]->(movie)
RETURN movie.title
$$) as (title agtype);

    title
-------------
'Wall Street'
(1 row)
```

Returns any vertices connected with the `Person` “Oliver” by an outgoing edge.

H.1.9.2.2. Directed Edges and Variable

If a variable is required, either for filtering on properties of the edge, or to return the edge, specify the variable within the edge or vertex you wish to use.

```
SELECT * FROM cypher('graph_name', $$
MATCH (:Person {name: 'Oliver Stone'})-[r]->(movie)
RETURN type(r)
$$) as (title agtype);

  title
----------
'DIRECTED'
(1 row)
```

Returns the type of each outgoing edge from “Oliver”.

H.1.9.2.3. Match on Edge Label

When you know the edge label you want to match on, you can specify it by using a colon together with the edge label

```
SELECT * FROM cypher('graph_name', $$
MATCH (:Movie {title: 'Wall Street'})<-[:ACTED_IN]-(actor)
RETURN actor.name
$$) as (actors_name agtype);

   actors_name
-----------------
'Charlie Sheen'
'Martin Sheen'
'Michael Douglas'
(3 rows)
```

Returns all actors that `ACTED_IN` “Wall Street”.

H.1.9.2.4. Match on Edge Label with a Variable

If you want to use a variable to hold the edge, and specify the edge label you want, you can do so by specifying them both.

```
SELECT * FROM cypher('graph_name', $$
MATCH ({title: 'Wall Street'})<-[r:ACTED_IN]-(actor)
RETURN r.role
$$) as (role agtype);

     role
--------------
'Gordon Gekko'
'Carl Fox'
'Bud Fox'
(3 rows)
```

Returns `ACTED_IN` roles for “Wall Street”.

H.1.9.2.5. Multiple Edges

Edges can be strung together to match an infinite number of edges. As long as the base pattern `()-[]-()` is followed, users can chain together edges and vertices to match specific patterns.

```
SELECT * FROM cypher('graph_name', $$
    MATCH (charlie {name: 'Charlie Sheen'})-[:ACTED_IN]->(movie)<-[:DIRECTED]-
(director)
    RETURN movie.title, director.name
```

```
$$) as (title agtype, name agtype);

    title     |     name
--------------+--------------
'Wall Street' | 'Oliver Stone'
(1 row)
```

Returns the movie “Charlie Sheen” acted in and its director.

H.1.9.3. Variable Length Edges

When the connection between two vertices is of variable length, the list of edges that form the connection can be returned using the following connection.

Rather than describing a long path using a sequence of many vertex and edge descriptions in a pattern, many edges (and the intermediate vertices) can be described by specifying a length in the edge description of a pattern.

```
(u)-[*2]->(v)
```

Which describes a right directed path of three vertices and two edges can be rewritten to:

```
(u)-[]->()-[]->(v)
```

A range length can also be given:

```
(u)-[*3..5]->(v)
```

Which is equivalent to:

```
(u)-[]->()-[]->()-[]->(v) and
(u)-[]->()-[]->()-[]->()-[]->(v) and
(u)-[]->()-[]->()-[]->()-[]->()-[]->(v)
```

The previous example provided gave the path both a lower and upper bound for the number of edges (and vertices) between `u` and `v`. Either one or both of these binding values can be excluded.

```
(u)-[*3..]->(v)
```

Returns all paths between `u` and `v` that have three or more edges included.

```
(u)-[*..5]->(v)
```

Returns all paths between `u` and `v` that have 5 or fewer edges included.

```
(u)-[*]->(v)
```

Returns all paths between `u` and `v`.

H.1.9.3.1. Example

```
SELECT * FROM cypher('graph_name', $$
    MATCH p = (actor {name: 'Willam Dafoe'})-[:ACTED_IN*2]-(co_actor)
    RETURN relationships(p)
$$) as (r agtype);

                                                                                                r
-----------------------------------------------------------------------------------------------------------------------------------
[{id: 0; label:"ACTED_IN"; properties: {role: "Green Goblin"}}::edge, {id: 1; label:
 "ACTED_IN; properties: {role: "Spiderman", actor: "Toby Maguire}}::edge]
[{id: 0; label:"ACTED_IN"; properties: {role: "Green Goblin"}}::edge, {id: 2; label:
 "ACTED_IN; properties: {role: "Spiderman", actor: "Andrew Garfield"}}::edge]
(2 rows)
```

Returns the list of edges, including the one that “Willam Dafoe” acted in and the two “Spiderman” actors he worked with.

H.1.10. WITH

Using `WITH`, you can manipulate the output before it is passed on to the following query parts. The manipulations can be of the shape and/or number of entries in the result set.

`WITH` can also, like `RETURN`, alias expressions that are introduced into the results using the aliases as the binding name.

`WITH` is also used to separate the reading of the graph from updating of the graph. Every part of a query must be either read-only or write-only. When going from a writing part to a reading part, an optional `WITH` clause can be used to do so.

H.1.10.1. Filter on Aggregate Function Results

Aggregated results have to pass through a `WITH` clause to be able to filter on.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (david {name: 'David'})-[]-(otherPerson)-[]->()
    WITH otherPerson, count(*) AS foaf
    WHERE foaf > 1
    RETURN otherPerson.name
$$) as (name agtype);

  name
--------
"Anders"
(1 row)
```

The name of the person connected to “David” with the at least more than one outgoing relationship will be returned by the query.

H.1.10.2. Sort Results Before Using `collect`

You can sort results before passing them to `collect`, thus sorting the resulting list.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)WITH n
    ORDER BY n.name DESC LIMIT 3
    RETURN collect(n.name)
$$) as (names agtype);

         names
-------------------------
["Emil","David","Ceasar"]
(1 row)
```

A list of the names of people in reverse order, limited to 3, is returned.

H.1.10.3. Limit Branching of a Path Search

You can match paths, limit to a certain number, and then match again using those paths as a base, as well as any number of similar limited searches.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'Anders'})-[]-(m)WITH m
    ORDER BY m.name DESC LIMIT 1
    MATCH (m)-[]-(o)
    RETURN o.name
```

```
$$) as (name agtype);

  name
-------
"Anders"
"Bossman"
(2 rows)
```

Starting at “Anders”, find all matching nodes, order by name descending and get the top result, then find all the nodes connected to that top result, and return their names.

H.1.11. RETURN

In the `RETURN` part of your query, you define which parts of the pattern you want to output. Output can include `agtype` values, nodes, relationships, or properties.

H.1.11.1. Return Nodes

To return a node, list it in the `RETURN` statement.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'B'})
    RETURN n
$$) as (n agtype);

                         n
-----------------------------------------------------
{id: 0; label: '' properties: {name: 'B'}}::vertex
(1 row)
```

The example will return the node.

H.1.11.2. Return Edges

To return `n` edges, just include it in the `RETURN` list.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)-[r:KNOWS]->()
    WHERE n.name = 'A'
    RETURN r
$$) as (r agtype);

                                 r
-------------------------------------------------------------------
 {id: 2; startid: 0; endid: 1; label: 'KNOWS' properties: {}}::edge
(1 row)
```

The relationship is returned by the example.

H.1.11.3. Return Property

To return a property, use the dot separator, as follows:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'A'})
    RETURN n.name
$$) as (name agtype);

 name
```

```
------
 'A'
(1 row)
```

The value of the property `name` gets returned.

H.1.11.4. Return All Elements

When you want to return all vertices, edges and paths found in a query, you can use the `*` symbol.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (a {name: 'A'})-[r]->(b)
    RETURN *
$$) as (a agtype, b agtype, r agtype);

                                                a
                 |                                                                                b
                                                        |
   r
-------------------------------------------------------------------------------------------------
+-----------------------------------------------------------------------------------------------
+-----------------------------------------------------------------------
 {"id": 281474976710659, "label": "", "properties": {"age": 55, "name": "A",
 "happy": "Yes!"}}::vertex | {"id": 1125899906842625, "label": "BLOCKS", "end_id":
 281474976710660, "start_id": 281474976710659, "properties": {}}::edge | {"id":
 281474976710660, "label": "", "properties": {"name": "B"}}::vertex
 {"id": 281474976710659, "label": "", "properties": {"age": 55, "name": "A",
 "happy": "Yes!"}}::vertex | {"id": 1407374883553281, "label": "KNOWS", "end_id":
 281474976710660, "start_id": 281474976710659, "properties": {}}::edge | {"id":
 281474976710660, "label": "", "properties": {"name": "B"}}::vertex
(2 rows)
```

This returns the two vertices, and the edge used in the query.

H.1.11.5. Variable with Uncommon Characters

To introduce a placeholder that is made up of characters that are not contained in the English alphabet, you can use the ` to enclose the variable, like this:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (`This isn\'t a common variable`)
    WHERE `This isn\'t a common variable`.name = 'A'
    RETURN `This isn\'t a common variable`.happy
$$) as (happy agtype);

 happy
-------
 "Yes!"
(1 row)
```

The node with name “A” is returned.

H.1.11.6. Aliasing a Field

If the name of the field should be different from the expression used, you can rename it by changing the name in the column list definition.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'A'})
```

```
    RETURN n.name
$$) as (objects_name agtype);

 objects_name
--------------
 'A'
(1 row)
```

Returns the property of a node, but renames the field.

H.1.11.7. Optional Properties

If a property might or might not be there, it will be treated as `null` if it is missing.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    RETURN n.age
$$) as (age agtype);

 age
-----
 55
 NULL
(2 rows)
```

This query returns the property if it exists, or `null` if the property does not exist.

H.1.11.8. Other Expressions

Any expression can be used as a return item—literals, predicates, properties, functions, and everything else.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (a)
    RETURN a.age > 30, 'I\'m a literal', id(a)
$$) as (older_than_30 agtype, literal agtype, id agtype);

 older_than_30 | literal         | id
---------------+-----------------+----
 true          | 'I'm a literal' | 1
(1 row)
```

Returns a predicate, a literal and function call with a pattern expression parameter.

H.1.11.9. Unique Results

`DISTINCT` retrieves only unique records depending on the fields that have been selected to output.

```
SELECT *
FROM cypher('graph_name', $$
MATCH (a {name: 'A'})-[]->(b)
RETURN DISTINCT b
$$) as (b agtype);

                            b
-------------------------------------------------
 {id: 1; label: '' properties: {name: 'B'}}::vertex
(1 row)
```

The node named “B” is returned by the query, but only once.

H.1.12. ORDER BY

`ORDER BY` is a sub-clause following `WITH`. `ORDER BY` specifies that the output should be sorted and how it will be sorted.

Note that you cannot sort on nodes or relationships, sorting must be done on properties. `ORDER BY` relies on comparisons to sort the output. See ordering and comparison of values.

In terms of scope of variables, `ORDER BY` follows special rules, depending on if the projecting `RETURN` or `WITH` clause is either aggregating or `DISTINCT`. If it is an aggregating or `DISTINCT` projection, only the variables available in the projection are available. If the projection does not alter the output cardinality (which aggregation and `DISTINCT` do), variables available from before the projecting clause are also available. When the projection clause shadows already existing variables, only the new variables are available.

Lastly, it is not allowed to use aggregating expressions in the `ORDER BY` sub-clause if they are not also listed in the projecting clause. This last rule is to make sure that `ORDER BY` does not change the results, only the order of them.

H.1.12.1. Order Nodes by Property

`ORDER BY` is used to sort the output.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    WITH n.name as name, n.age as age
    ORDER BY n.name
    RETURN name, age
$$) as (name agtype, age agtype);
```

```
  name   | age
---------+-----
  "A"    | 34
  "B"    | 34
  "C"    | 32
(3 rows)
```

The nodes are returned, sorted by their name.

H.1.12.2. Order Nodes by Multiple Properties

You can order by multiple properties by stating each variable in the `ORDER BY` clause. Cypher will sort the result by the first variable listed, and for equal values, go to the next property in the `ORDER BY` clause, and so on.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    WITH n.name as name, n.age as age
    ORDER BY n.age, n.name
    RETURN name, age
$$) as (name agtype, age agtype);
```

```
  name   | age
---------+-----
  "C"    | 32
  "A"    | 34
  "B"    | 34
(3 rows)
```

This returns the nodes, sorted first by their age, and then by their name.

H.1.12.3. Order Nodes in Descending Order

By adding `DESC[ENDING]` after the variable to sort on, the sort will be done in reverse order.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    WITH n.name AS name, n.age AS age
    ORDER BY n.name DESC
    RETURN name, age
$$) as (name agtype, age agtype);

  name  | age
--------+-----
  "C"   | 32
  "B"   | 34
  "A"   | 34
(3 rows)
```

The example returns the nodes, sorted by their name in reverse order.

H.1.12.4. Ordering null

When sorting the result set, `null` will always come at the end of the result set for ascending sorting, and first for descending sorting.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    WITH n.name AS name, n.age AS age, n.height AS height
    ORDER BY n.height
    RETURN name, age, height
$$) as (name agtype, age agtype, height agtype);

  name  | age | height
--------+-----+--------
  "A"   | 34  | 170
  "C"   | 32  | 185
  "B"   | 34  | NULL
(3 rows)
```

The nodes are returned sorted by the length property, with a node without that property last.

H.1.13. SKIP

`SKIP` defines from which record to start including the records in the output.

By using `SKIP`, the result set will get trimmed from the top. Please note that no guarantees are made on the order of the returned results unless specified by the `ORDER BY` clause. `SKIP` accepts any expression that evaluates to a positive integer.

H.1.13.1. Skip First Three Rows

To return a subset of the result, starting from the top, use the following syntax:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    RETURN n.name
    ORDER BY n.name
```

```
    SKIP 3
$$) as (names agtype);

 names
-------
 "D"
 "E"
(2 rows)
```

The name property of the matched node `n` is returned, with a limit of 3.

H.1.13.2. Return Middle Two Rows

To return a subset of the result, starting in the middle, use this syntax:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    RETURN n.name
    ORDER BY n.name
    SKIP 1
    LIMIT 2
$$) as (names agtype);

 names
-------
 "B"
 "C"
(2 rows)
```

Two vertices from the middle are returned.

H.1.13.3. Using an Expression with SKIP to Return a Subset of Rows

Using an expression with `SKIP` to return a subset of the rows.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    RETURN n.name
    ORDER BY n.name
    SKIP (3 * rand())+ 1
$$) as (a agtype);

 names
-------
 "C"
 "D"
 "E"
(3 rows)
```

The first two vertices are skipped, and only the last three are returned in the result.

H.1.14. LIMIT

`LIMIT` constrains the number of records in the output.

`LIMIT` accepts any expression that evaluates to a positive integer.

H.1.14.1. Return a Subset of the Rows

To return a subset of the result, starting from the top, use this syntax:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)RETURN n.name
    ORDER BY n.name
    LIMIT 3
$$) as (names agtype);

names
"A"
"B"
"C"
3 rows
```

The node is returned, and no property `age` exists on it.

H.1.14.2. Using an Expression with LIMIT to Return a Subset of Rows

`LIMIT` accepts any expression that evaluates to a positive integer as long as it is not referring to any external variables:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n)
    RETURN n.name
    ORDER BY n.name
    LIMIT toInteger(3 * rand()) + 1
$$) as (names agtype);

 names
-------
 "A"
 "B"
(2 rows)
```

Returns one to three top items.

H.1.15. CREATE

The `CREATE` clause is used to create graph vertices and edges.

H.1.15.1. Terminal CREATE Clauses

A `CREATE` clause that is not followed by another clause is a terminal clause. When the Cypher query ends with a terminal clause, no results will be returned from the Cypher function call. However, the Cypher function call still requires a column list definition. When the Cypher query ends with a terminal node, define a single value in the column list definition: no data will be returned in this variable.

```
SELECT *
FROM cypher('graph_name', $$
    CREATE /* Create clause here, no following clause */
$$) as (a agtype);

 a
---
(0 rows)
```

H.1.15.2. Create Single Vertex

Creating a single vertex is done by issuing the following query.

```
SELECT *
```

```
FROM cypher('graph_name', $$
    CREATE (n)
$$) as (v agtype);

 v
---
(0 rows)
```

Nothing is returned from this query.

H.1.15.3. Create Multiple Vertices

Creating multiple vertices is done by separating them with a comma.

```
SELECT *
FROM cypher('graph_name', $$
    CREATE (n), (m)
$$) as (v agtype);

   a
-------
(0 rows)
```

H.1.15.4. Create a Vertex with a Label

To add a label when creating a vertex, use the syntax below.

```
SELECT *
FROM cypher('graph_name', $$
    CREATE (:Person)
$$) as (v agtype);

   v
-------
(0 rows)
```

Nothing is returned from this query.

H.1.15.5. Create Vertex and Add Labels and Properties

You can create a vertex with labels and properties at the same time.

```
SELECT *
FROM cypher('graph_name', $$
    CREATE (:Person {name: 'Andres', title: 'Developer'})
$$) as (n agtype);

   n
-------
(0 rows)
```

Nothing is returned from this query.

H.1.15.6. Return Created Node

You can create and return a node within the same query as follows:

```
SELECT *
FROM cypher('graph_name', $$
    CREATE (a {name: 'Andres'})
    RETURN a
$$) as (a agtype);
```

```
                                        a
------------------------------------------------------------------------------
 {"id": 281474976710660, "label": "", "properties": {"name": "Andres"}}::vertex
(1 row)
```

The newly-created node is returned.

H.1.15.7. Create an Edge Between Two Nodes

To create an edge between two vertices, we first `MATCH` the two vertices. Once the nodes are matched, we create an edge between them.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (a:Person), (b:Person)
    WHERE a.name = 'Node A' AND b.name = 'Node B'
    CREATE (a)-[e:RELTYPE]->(b)
    RETURN e
$$) as (e agtype);

                               e
--------------------------------------------------------------------
{id: 3; startid: 0, endid: 1; label: 'RELTYPE'; properties: {}}::edge
(1 row)
```

The created edge is returned by the query.

H.1.15.8. Create an Edge and Set Properties

Setting properties on edges is done in a similar manner to setting properties when creating vertices. Note that the values can be any expression.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (a:Person), (b:Person)
    WHERE a.name = 'Node A' AND b.name = 'Node B'
    CREATE (a)-[e:RELTYPE {name:a.name + '<->' + b.name}]->(b)
    RETURN e
$$) as (e agtype);

                                          e
-----------------------------------------------------------------------------------------------
 {id: 3; startid: 0, endid: 1; label: 'RELTYPE'; properties: {name: 'Node A<->Node
 B'}}::edge
(1 row)
```

The newly created edge is returned by the example query.

H.1.15.9. Create a Full Path

When you use `CREATE` and a pattern, all parts of the patterns that are not already in scope at this time will be created.

```
SELECT *
FROM cypher('graph_name', $$
    CREATE p = (andres {name:'Andres'})-[:WORKS_AT]->(neo)<-[:WORKS_AT]-(michael
 {name:'Michael'})
    RETURN p
$$) as (p agtype);

                     p
-----------------------------------------------------------------------------------------------
```

```
 [{"id": 281474976710661, "label": "", "properties": {"name": "Andres"}}::vertex,
 {"id": 1407374883553282, "label": "WORKS_AT", "end_id": 281474976710662, "start_id":
 281474976710661, "properties": {}}::edge, {"id": 281474976710662, "label": "",
 "properties": {}}::vertex, {"id": 1407374883553281, "label": "WORKS_AT", "end_id":
 281474976710662, "start_id": 281474976710663, "properties": {}}::edge, {"id":
 281474976710663, "label": "", "properties": {"name": "Michael"}}::vertex]::path
(1 row)
```

This query creates three nodes and two relationships simultaneously, assigns the pattern to a path variable, and returns the said pattern.

H.1.16. DELETE

The `DELETE` clause is used to delete graph elements — nodes, relationships, or paths.

A `DELETE` clause that is not followed by another clause is called a terminal clause. When the Cypher query ends with a terminal clause, no results will be returned from the Cypher function call. However, the Cypher function call still requires a column list definition. When the Cypher query ends with a terminal node, define a single value in the column list definition: no data will be returned in this variable.

For removing properties, see Section H.1.17.4.

You cannot delete a node without also deleting edges that start or end on said vertex. Either explicitly delete the vertices,or use `DETACH DELETE`.

H.1.16.1. Delete Isolated Vertices

To delete a vertex, use the `DELETE` clause.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (v:Useless)
    DELETE v
$$) as (v agtype);

   v
-------
(0 rows)
```

This will delete the vertices (with label Useless) that have no edges. Nothing is returned from this query.

H.1.16.2. Delete All Vertices and Edges Associated with Them

Running a `MATCH` clause will collect all nodes — use the `DETACH` option to delete vertice edges first, and then delete the vertex itself.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (v:Useless)
    DETACH DELETE v
$$) as (v agtype);

   v
-------
(0 rows)
```

Nothing is returned from this query.

H.1.16.3. Delete Edges Only

To delete an edge, use the `MATCH` clause to find your edges, then add the variable to the `DELETE` clause.

```
SELECT *
```

```
FROM cypher('graph_name', $$
    MATCH (n {name: 'Andres'})-[r:KNOWS]->()
    DELETE r
$$) as (v agtype);

   v
-------
(0 rows)
```

Nothing is returned from this query.

H.1.16.4. Return a Deleted Vertex

You can return vertices that have been deleted with a `RETURN` clause.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'A'})
    DELETE n
    RETURN n
$$) as (a agtype);

                                    a
-------------------------------------------------------------------------
 {"id": 281474976710659, "label": "", "properties": {"name": "A"}}::vertex
(1 rows)
```

H.1.17. SET

The `SET` clause is used to update labels and properties on vertices and edges.

H.1.17.1. Terminal SET Clauses

A `SET` clause that is not followed by another clause is a terminal clause. When the Cypher query ends with a terminal clause, no results will be returned from the Cypher function call. However, the Cypher function call still requires a column list definition. When the Cypher query ends with a terminal node, define a single value in the column list definition: no data will be returned in this variable.

H.1.17.2. Set a Property

To set a property on a node or relationship, use `SET`.

```
SELECT *
FROM cypher('graph_name', $$
   MATCH (v {name: 'Andres'})
   SET v.surname = 'Taylor'
$$) as (v agtype);

   v
-------
(0 rows)
```

The newly changed node is returned by the query.

H.1.17.3. Return Created Vertex

Creating a single vertex is done with the following query:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (v {name: 'Andres'})
    SET v.surname = 'Taylor'
```

```
    RETURN v
$$) as (v agtype);

                                                    v
-------------------------------------------------------------------------------------------
 {id: 3; label: 'Person'; properties: {surname:"Taylor", name:"Andres", age:36,
 hungry:true}}::vertex
(1 row)
```

The newly changed vertex is returned by the query.

H.1.17.4. Remove a Property

Normally a property can be removed by using `REMOVE`, but users can also remove properties using the `SET` command. One example is if the property comes from a parameter.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (v {name: 'Andres'})
    SET v.name = NULL
    RETURN v
$$) as (v agtype);

                                          v
-------------------------------------------------------------------------------------
 {id: 3; label: 'Person'; properties: {surname:"Taylor", age:36, hungry:true}}::vertex
(1 row)
```

The node is returned by the query, and the name property is now missing.

H.1.17.5. Set Multiple Properties Using One SET Clause

If you want to set multiple properties in one query, you can separate them with a comma.

```
SELECT *
FROM cypher('graph_name', $$
MATCH (v {name: 'Andres'})
SET v.position = 'Developer', v.surname = 'Taylor'
RETURN v
$$) as (v agtype);

                                                    v
-------------------------------------------------------------------------------------------
{"id": 281474976710661, "label": "", "properties": {"name": "Andres", "surname":
 "Taylor", "position": "Developer"}}: :vertex
(1 row)
```

H.1.18. REMOVE

The `REMOVE` clause is used to remove properties from vertex and edges.

A `REMOVE` clause that is not followed by another clause is called a terminal clause. When the Cypher query ends with a terminal clause, no results will be returned from the Cypher function call. However, the Cypher function call still requires a column list definition. When the Cypher query ends with a terminal node, define a single value in the column list definition: no data will be returned in this variable.

Cypher does not allow storing `null` in properties. Instead, if no value exists, the property is just not there. So, removing a property value on a node or a relationship is also done with `REMOVE`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (andres {name: 'Andres'})
```

```
    REMOVE andres.age
    RETURN andres
$$) as (andres agtype);

                           andres
------------------------------------------------------------
 {id: 3; label: 'Person'; properties: {name:"Andres"}}::vertex
(1 row)
```

The node is returned, and no property `age` exists on it.

H.1.19. MERGE

The `MERGE` clause ensures that a pattern exists in the graph. Either the pattern already exists, or it needs to be created.

`MERGE` either matches existing nodes, or creates new data. It is a combination of `MATCH` and `CREATE`.

For example, you can specify that the graph must contain a node for a user with a certain name. If there is not a node with the correct name, a new node will be created and its name property set. When using `MERGE` on full patterns, the behavior is that either the whole pattern matches, or the whole pattern is created. `MERGE` will not partially use existing patterns. If partial matches are needed, this can be accomplished by splitting a pattern up into multiple `MERGE` clauses.

As with `MATCH`, `MERGE` can match multiple occurrences of a pattern. If there are multiple matches, they will all be passed on to later stages of the query.

```
SELECT * from cypher('graph_name', $$
CREATE (A:Person {name: 'Charlie Sheen', bornIn: 'New York'}),
    (B:Person {name: 'Michael Douglas', bornIn: 'New Jersey'}),
    (C:Person {name: 'Rob Reiner', bornIn: 'New York'}),
    (D:Person {name: 'Oliver Stone', bornIn: 'New York'}),
    (E:Person {name: 'Martin Sheen', bornIn: 'Ohio'})
$$) as (result agtype);
```

H.1.19.1. Merge Nodes

H.1.19.1.1. Merge a Node with a Label

By just specifying a pattern with a single vertex and no labels, all vertices in the graph will be returned.

```
SELECT * FROM cypher('graph_name', $$
MERGE (v:Critic)
RETURN v
$$) as (v agtype);

                     v
-----------------------------------------------
 {id: 0; label: 'Critic': properties:{}}::vertex
(1 row)
```

If there exists a vertex with the label “Critic”, that vertex will be returned. Otherwise, the vertex will be created and returned.

H.1.19.1.2. Merge Single Vertex with Properties

Merging a vertex node with properties where not all properties match any existing vertex.

```
SELECT * FROM cypher('graph_name', $$
MERGE (charlie {name: 'Charlie Sheen', age: 10})
RETURN charlie
$$) as (v agtype);
```

```
                                        v
------------------------------------------------------------------------------
 {id: 0; label: 'Actor': properties:{name: 'Charlie Sheen', age: 10}}::vertex
(1 row)
```

If there exists a vertex with the label “Critic”, that vertex will be returned. Otherwise, the vertex will be created and returned.

If there exists a vertex with all properties, that vertex will be returned. Otherwise, a new vertex with the name “Charlie Sheen” will be created and returned.

H.1.19.1.3. Merge a Single Vertex Specifying Both Label and Property

Merging a vertex where both label and property constraints match an existing vertex.

```
SELECT * FROM cypher('graph_name', $$
MERGE (michael:Person {name: 'Michael Douglas'})
RETURN michael.name, michael.bornIn
$$) as (Name agtype, BornIn agtype);

       name        |    bornin
-------------------+--------------
 "Michael Douglas" | "New Jersey"
(1 row)
```

“Michael Douglas” will match the existing vertex, and the vertex `name` and `bornIn` properties will be returned.

H.1.20. Predicate Functions

Predicates are boolean functions that return true or false for a given set of input. They are most commonly used to filter out subgraphs in the `WHERE` part of a query.

`exists(`*property* `agtype) returns agtype boolean`

`exists()` returns `true` if the specified property exists in the node, relationship or map. This is different from the `EXISTS` clause.

```
SELECT *
FROM cypher('graph_name', $$
     MATCH (n)
     WHERE exists(n.surname)
     RETURN n.first_name, n.last_name
$$) as (first_name agtype, last_name agtype);

 first_name |  last_name
------------+------------
   'John'   |   'Smith'
   'Patty' | 'Patterson'
(2 rows)
```

`exists(`*path* `agtype) returns agtype boolean`

`exists()` returns `true` if for the given path, there already exists the given path.

```
SELECT *
FROM cypher('graph_name', $$
     MATCH (n)
     WHERE exists((n)-[]-({name: 'Willem Defoe'}))
     RETURN n.full_name
$$) as (full_name agtype);
```

```
      full_name
    --------------
    'Toby Maguire'
    'Tom Holland'
    (2 rows)
```

H.1.21. Scalar Functions

`id(`*`expression`* `agtype) returns agtype integer`

`id()` returns the ID of a vertex or edge.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (a)
    RETURN id(a)
$$) as (id agtype);

 id
----
 0
 1
 2
 3
(4 rows)
```

`start_id(`*`expression`* `agtype) returns agtype integer`

`start_id()` returns the ID of the vertex that is the starting vertex for the edge.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH ()-[e]->()
    RETURN start_id(e)
$$) as (start_id agtype);

 start_id
----------
 0
 1
 2
 3
(4 rows)
```

`end_id(`*`expression`* `agtype) returns agtype integer`

`end_id()` returns the ID of the vertex that is the ending vertex for the edge.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH ()-[e]->()
    RETURN end_id(e)
$$) as (end_id agtype);

 end_id
--------
 4
 5
 6
 7
(4 rows)
```

`type(`*`edge`* `agtype) returns agtype string`

`type()` returns the string representation of the edge type.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH ()-[e]->()
    RETURN type(e)
$$) as (type agtype);

 type
------
'KNOWS'
'KNOWS'
(2 rows)
```

`properties(`*`expression`* `agtype) returns agtype map`

`properties()` returns an agtype map containing all the properties of a vertex or edge. If the argument is already a map, it is returned unchanged. `properties(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    CREATE (p:Person {name: 'Stefan', city: 'Berlin'})
    RETURN properties(p)
$$) as (type agtype);

                  type
-------------------------------------
 {"city": "Berlin", "name": "Stefan"}
(1 row)
```

`head(`*`list`* `agtype) returns agtype`

`head()` returns the first element in an agtype list. `head(null)` returns `null`. If the first element in the list is `null`, `head(list)` will return `null`.

```
SELECT *
FROM cypher('graph_name', $$
   MATCH (a)
   WHERE a.name = 'Eskil'
   RETURN a.array, head(a.array)
$$) as (lst agtype, lst_head agtype);

          lst          | lst_head
-----------------------+----------
 ["one","two","three"] | "one"
(1 row)
```

`last(`*`list`* `agtype) returns agtype`

`last()` returns the last element in an agtype list. `last(null)` returns `null`. If the last element in the list is `null`, `last(list)` will return `null`.

```
SELECT *
FROM cypher('graph_name', $$
MATCH (a)
WHERE a.name = 'Eskil'
RETURN a.array, last(a.array)
$$) as (lst agtype, lst_tail agtype);

          lst          | lst_tail
```

```
----------------------+----------
 ["one","two","three"] | "three"
(1 row)
```

`length(`*`path`* `agtype) returns agtype integer`

`length()` returns the length of a path. `length(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
   MATCH p = (a)-[]->(b)-[]->(c)
   WHERE a.name = 'Alice'
   RETURN length(p)
$$) as (length_of_path agtype);

 length_of_path
----------------
 2
 2
 2
(3 rows)
```

`size(`*`list`* `variadic "any") returns agtype integer`

`size()` returns the length of a list. `size(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN size(['Alice', 'Bob'])
$$) as (size_of_list agtype);

 size_of_list
--------------
 2
(1 row)
```

`startNode(`*`edge`* `agtype) returns agtype`

`startNode()` returns the start node of an edge. `startNode(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (x:Developer)-[r]-()
    RETURN startNode(r)
$$) as (v agtype);

                    v
-----------------------------------------
Node[0]{name:"Alice",age:38,eyes:"brown"}
Node[0]{name:"Alice",age:38,eyes:"brown"}
(2 rows)
```

`endNode(`*`edge`* `agtype) returns agtype`

`endNode()` returns the end node of an edge. `endNode(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (x:Developer)-[r]-()
    RETURN endNode(r)
$$) as (v agtype);

                    v
```

```
-----------------------------------------
Node[2]{name:"Charlie",age:53,eyes:"green"}
Node[1]{name:"Bob",age:25,eyes:"blue"}
(2 rows)
```

`timestamp() returns agtype integer`

`timestamp()` returns the difference, measured in milliseconds, between the current time and midnight, January 1, 1970 UTC. `timestamp` will return the same value during one entire query, even for long-running queries.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN timestamp()
$$) as (t agtype);

       t
---------------
1613496720760
(1 row)
```

`toBoolean(`*`expression`* `variadic "any") returns agtype boolean`

`toBoolean()` converts a string value to a boolean value. `toBoolean(null)` returns `null`. If expression is a boolean value, it will be returned unchanged. If the parsing fails, `null` will be returned.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN toBoolean('TRUE'), toBoolean('not a boolean')
$$) as (a_bool agtype, not_a_bool agtype);

 a_bool | not_a_bool
--------+------------
 true   | NULL
(1 row)
```

`toFloat(`*`expression`* `variadic "any") returns agtype float`

`toFloat()` converts an integer or string value to a floating point number. `toFloat(null)` returns `null`. If expression is a floating point number, it will be returned unchanged. If the parsing fails, `null` will be returned.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN toFloat('11.5'), toFloat('not a number')
$$) as (a_float agtype, not_a_float agtype);

 a_float | not_a_float
---------+-------------
 11.5    | NULL
(1 row)
```

`toInteger(`*`expression`* `variadic "any") returns agtype integer`

`toInteger()` converts a floating point or string value to an integer value. `toInteger(null)` returns `null`. If expression is an integer value, it will be returned unchanged. If the parsing fails, `null` will be returned.

```
SELECT *
FROM cypher('graph_name', $$
     RETURN toInteger('42'), toInteger('not a number')
$$) as (an_integer agtype, not_an_integer agtype);
```

```
 an_integer | not_an_integer
------------+----------------
 42         | NULL
(1 row)
```

`coalesce(`*`expression`* `agtype [, `*`expression`* `agtype]*) returns agtype`

`coalesce()` returns the first non-null value in the given list of expressions. `null` will be returned if all the arguments are `null`.

```
SELECT *
FROM cypher('graph_name', $$
MATCH (a)
WHERE a.name = 'Alice'
RETURN coalesce(a.hairColor, a.eyes), a.hair_color, a.eyes
$$) as (color agtype, hair_color agtype, eyes agtype);

 color | hair_color |  eyes
-------+------------+--------
“brown”| NULL       | “Brown”
(1 row)
```

H.1.22. List Functions

```
SELECT * from cypher('graph_name', $$
CREATE (A:Person {name: 'Alice', age: 38, eyes: 'brown'}),
    (B:Person {name: 'Bob', age: 25, eyes: 'blue'}),
    (C:Person {name: 'Charlie', age: 53, eyes: 'green'}),
    (D:Person {name: 'Daniel', age: 54, eyes: 'brown'}),
    (E:Person {name: 'Eskil', age: 41, eyes: 'blue', array: ['one', 'two', 'three']}),
    (A)-[:KNOWS]->(B),
    (A)-[:KNOWS]->(C),
    (B)-[:KNOWS]->(D),
    (C)-[:KNOWS]->(D),
    (B)-[:KNOWS]->(E)
$$) as (result agtype);
```

`keys(`*`expression`* `agtype) returns agtype list`

`keys()` returns a list containing the string representations for all the property names of a vertex, edge, or map. `keys(null)` returns `null`.

```
SELECT * from cypher('graph_name', $$
    MATCH (a)
    WHERE a.name = 'Alice'
    RETURN keys(a)
$$) as (result agtype);

          result
------------------------
 ["age", "eyes", "name"]
(1 row)
```

A list containing the names of all the properties on the vertex bound to `a` is returned.

`range(`*`start`* `variadic "any", `*`end`* `variadic "any" [, `*`step`* `variadic "any"]) returns agtype list`

`range()` returns a list comprising all integer values within a range bounded by a start value *`start`* and end value *`end`*, where the difference *`step`* between any two consecutive values is constant; i.e. an arithmetic progression. The range is inclusive, and the arithmetic progression will therefore always contain *`start`* and — depending on the values of *`start`*, *`step`*, and *`end`* — *`end`*.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN range(0, 10), range(2, 18, 3)
$$) as (no_step agtype, step agtype);

              no_step               |         step
------------------------------------+-----------------------
 [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10] | [2, 5, 8, 11, 14, 17]
(1 row)
```

Two lists of numbers in the given ranges are returned.

`labels(vertex agtype) returns agtype list`

`labels()` returns a list containing the string representations for all the labels of a node. `labels(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (a)
    WHERE a.name = 'Alice'
    RETURN labels(a)
$$) as (edges agtype);

   edges
------------
 ["Person"]
(1 row)
```

A list containing all the labels of the node bound to `a` is returned.

`nodes(path agtype) returns agtype list`

`nodes()` returns a list containing all the vertices in a path. `nodes(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH p = (a)-[]->(b)-[]->(c)
    WHERE a.name = 'Alice' AND c.name = 'Eskil'
    RETURN nodes(p)
$$) as (vertices agtype);

             vertices
-------------------------------------------------------------------------------------------------
 [{"id": 844424930131969, "label": "Person", "properties": {"age": 38, "eyes":
 "brown", "name": "Alice"}}::vertex, {"id": 844424930131970, "label": "Person",
 "properties": {"age": 25, "eyes": "blue", "name": "Bob"}}::vertex, {"id":
 844424930131973, "label": "Person", "properties": {"age": 41, "eyes": "blue",
 "name": "Eskil", "array": ["one", "two", "three"]}}::vertex]
(1 row)
```

A list containing all the vertices in the path `p` is returned.

`relationships(path agtype) returns agtype list`

`relationships()` returns a list containing all the relationships in a path. `relationships(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
```

```
    MATCH p = (a)-[]->(b)-[]->(c)
    WHERE a.name = 'Alice' AND c.name = 'Eskil'
    RETURN relationships(p)
$$) as (edges agtype);

                                        edges
-------------------------------------------------------------------------------------------
 [{"id": 1125899906842625, "label": "KNOWS", "end_id": 844424930131970, "start_id":
 844424930131969, "properties": {}}::edge, {"id": 1125899906842629, "label":
 "KNOWS", "end_id": 844424930131973, "start_id": 844424930131970, "properties":
 {}}::edge]
(1 row)
```

A list containing all the edges in the path `p` is returned.

`toBooleanList(`*`list`* `variadic "any") returns agtype list`

`toBooleanList()` converts a list of values and returns a list of boolean values. If any values are not convertible to boolean they will be `null` in the list returned. Any `null` element in list is preserved. Any boolean value in list is preserved. If the list is `null`, `null` will be returned.

```
SELECT * FROM cypher('expr', $$
    RETURN toBooleanList(['true', 'false', 'true'])
$$) AS (toBooleanList agtype);

   toBooleanList
--------------------
[true, false, true]
(1 row)
```

H.1.23. Numeric Functions

`rand() returns agtype float`

`rand()` returns a random floating point number in the range from 0 (inclusive) to 1 (exclusive); i.e. [0,1). The numbers returned follow an approximate uniform distribution.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN rand()
$$) as (random_number agtype);

   random_number
-------------------
0.3586784748902053
(1 row)
```

`abs(`*`list`* `variadic "any") returns agtype`

`abs()` returns the absolute value of the given number. `abs(null)` returns `null`. If expression is negative, `-(`*`expression`*`)` (i.e. the negation of expression) is returned.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (a), (e) WHERE a.name = 'Alice' AND e.name = 'Eskil'
    RETURN a.age, e.age, abs(a.age - e.age)
$$) as (alice_age agtype, eskil_age agtype, difference agtype);

 alice_age | eskil_age | difference
-----------+-----------+------------
 38        | 41        | 3
```

```
(1 row)
```

The absolute value of the age difference is returned.

`ceil(`*`expression`* `variadic "any") returns agtype float`

`ceil()` returns the smallest floating point number that is greater than or equal to the given number and equal to a mathematical integer. `ceil(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN ceil(0.1)
$$) as (ceil_value agtype);

 ceil_value
------------
 1.0
(1 row)
```

The ceiling of 0.1 is returned.

`floor(`*`expression`* `variadic "any") returns agtype float`

`floor()` returns the greatest floating point number that is less than or equal to the given number and equal to a mathematical integer. `floor(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN floor(0.1)
$$) as (flr agtype);

 flr
-----
 0.0
(1 row)
```

The floor of 0.1 is returned.

`round(`*`expression`* `variadic "any") returns agtype float`

`round()` returns the value of the given number rounded to the nearest integer. `round(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN round(3.141592)
$$) as (rounded_value agtype);

 rounded_value
---------------
 3.0
(1 row)
```

`sign(`*`expression`* `variadic "any") returns agtype integer`

`sign()` returns the signum of the given number: 0 if the number is 0, -1 for any negative number, and 1 for any positive number. `sign(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN sign(-17), sign(0.1), sign(0)
$$) as (negative_sign agtype, positive_sign agtype, zero_sign agtype);
```

```
 negative_sign | positive_sign | zero_sign
---------------+---------------+-----------
 -1            | 1             | 0
(1 row)
```

The signs of -17 and 0.1 are returned.

H.1.24. Logarithmic Functions

`e() returns agtype float`

`e()` returns the base of the natural logarithm, `e`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN e()
$$) as (e agtype);

         e
------------------
 2.718281828459045
(1 row)
```

`sqrt(`*`expression`* `variadic "any") returns agtype float`

`sqrt()` returns the square root of a number.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN sqrt(144)
$$) as (results agtype);

 results
---------
 12.0
(1 row)
```

`exp(`*`expression`* `variadic "any") returns agtype float`

`exp()` returns `e^n`, where `e` is the base of the natural logarithm, and `n` is the value of the argument expression. `exp(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN exp(2)
$$) as (e agtype);

        e
------------------
 7.38905609893065
(1 row)
```

`e` to the power of 2 is returned.

`log(`*`expression`* `variadic "any") returns agtype float`

`log()` returns the natural logarithm of a number. `log(null)` returns `null`. `log(0)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN log(27)
$$) as (natural_logarithm agtype);
```

```
 natural_logarithm
-------------------
 3.295836866004329
(1 row)
```

The natural logarithm of 27 is returned.

`log10(`*`expression`* `variadic "any") returns agtype float`

`log10()` returns the common logarithm (base 10) of a number. `log10(null)` returns `null`. `log10(0)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN log10(27)
$$) as (common_logarithm agtype);

  common_logarithm
--------------------
 1.4313637641589874
(1 row)
```

The common logarithm of 27 is returned.

H.1.25. Trigonometric Functions

`degrees(`*`expression`* `variadic "any") returns agtype float`

`degrees()` converts radians to degrees. `degrees(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN degrees(3.14159)
$$) as (deg agtype);

        deg
-------------------
 179.9998479605043
(1 row)
```

The number of degrees close to pi is returned.

`radians(`*`expression`* `variadic "any") returns agtype float`

`radians()` converts degrees to radians. `radians(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN radians(180)
$$) as (rad agtype);

        rad
-------------------
 3.141592653589793
(1 row)
```

The number of degrees close to pi is returned.

`pi() returns agtype float`

`pi()` returns the mathematical constant pi.

```
SELECT *
FROM cypher('graph_name', $$
```

```
        RETURN pi()
    $$) as (p agtype);

             p
    ------------------
     3.141592653589793
    (1 row)
```

The constant pi is returned.

`sin(`*expression* `variadic "any") returns agtype float`

`sin()` returns the sine of a number. `sin(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN sin(0.5)
$$) as (s agtype);

         s
------------------
 0.479425538604203
(1 row)
```

The sine of 0.5 is returned.

`cos(`*expression* `variadic "any") returns agtype float`

`cos()` returns the sine of a number. `cos(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN cos(0.5)
$$) as (c agtype);

         c
--------------------
 0.8775825618903728
(1 row)
```

The cosine of 0.5 is returned.

`tan(`*expression* `variadic "any") returns agtype float`

`tan()` returns the tangent of a number. `tan(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN tan(0.5)
$$) as (t agtype);

         t
--------------------
 0.5463024898437905
(1 row)
```

The tangent of 0.5 is returned.

`cot(`*expression* `variadic "any") returns agtype float`

`cot()` returns the cotangent of a number. `cot(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
```

```
    RETURN cot(0.5)
$$) as (t agtype);

          t
------------------
 1.830487721712452
(1 row)
```

The cotangent of 0.5 is returned.

`asin(`*`expression`* `variadic "any") returns agtype float`

`asin()` returns the arcsine of a number. `asin(null)` returns `null`. If (expression < -1) or (expression > 1), then `asin(expression)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN asin(0.5)
$$) as (arc_s agtype);

       arc_s
--------------------
 0.5235987755982989
(1 row)
```

The arcsine of 0.5 is returned.

`acos(`*`expression`* `variadic "any") returns agtype float`

`acos()` returns the arcsine of a number. `acos(null)` returns `null`. If (expression < -1) or (expression > 1), then `acos(expression)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN acos(0.5)
$$) as (arc_c agtype);

       arc_c
--------------------
 1.0471975511965979
(1 row)
```

The arccosine of 0.5 is returned.

`atan(`*`expression`* `variadic "any") returns agtype float`

`atan()` returns the arctangent of a number. `atan(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN atan(0.5)
$$) as (arc_t agtype);

       arc_t
--------------------
 0.4636476090008061
(1 row)
```

The arctangent of 0.5 is returned.

`atan2(`*`expression1`* `variadic "any",` *`expression2`* `variadic "any") returns agtype float`

`atan2()` returns the arctangent of a set of coordinates in radians. `atan2(null, null)`, `atan2(null, expression2)` and `atan(expression1, null)` all return `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN atan2(0.5, 0.6)
$$) as (arc_t2 agtype);

       arc_t2
--------------------
 0.6947382761967033
(1 row)
```

The arctangent of 0.5 and 0.6 is returned.

H.1.26. String Functions

`replace(`*`original`*`, `*`search`* `variadic "any", `*`replace`* `variadic "any") returns agtype string`

`replace()` returns a string in which all occurrences of a specified string in the original string have been replaced by another (specified) string. If any argument is `null`, `null` will be returned. If search is not found in *`original`*, *`original`* will be returned.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN replace('hello', 'l', 'w')
$$) as (str_array agtype);

 str_array
-----------
 "hewwo"
(1 row)
```

`split(`*`original`* `variadic "any", `*`split_delimiter`* `variadic "any") returns list of agtype strings`

`split()` returns a list of strings resulting from the splitting of the original string around matches of the given delimiter. `split(null, splitDelimiter)` and `split(original, null)` both return `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN split('one,two', ',')
$$) as (split_list agtype);

   split_list
----------------
 ["one", "two"]
(1 row)
```

`left(`*`original`* `variadic "any", `*`length`* `variadic "any") returns agtype string`

`left()` returns a string containing the specified number of leftmost characters of the original string. `left(null, length)` and `left(null, null)` both return `null`. `left(original, null)` will raise an error. If *`length`* is not a positive integer, an error is raised. If *`length`* exceeds the size of *`original`*, *`original`* is returned.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN left('Hello', 3)
$$) as (new_str agtype);

 new_str
---------
 "Hel"
(1 row)
```

`right(original variadic "any", length variadic "any") returns agtype string`

`right()` returns a string containing the specified number of rightmost characters of the original string. `right(null, length)` and `right(null, null)` both return `null`. `right(original, null)` will raise an error. If *`length`* is not a positive integer, an error is raised. If *`length`* exceeds the size of *`original`*, *`original`* is returned.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN right('hello', 3)
$$) as (new_str agtype);

 new_str
---------
 "llo"
(1 row)
```

`substring(original variadic "any", start variadic "any" [, length variadic "any"]) returns agtype string`

`substring()` returns a substring of the original string, beginning with a 0-based index start and length. *`start`* uses a zero-based index. If *`length`* is omitted, the function returns the substring starting at the position given by *`start`* and extending to the end of *`original`*. If *`original`* is `null`, `null` is returned. If either *`start`* or *`length`* is `null` or a negative integer, an error is raised. If *`start`* is 0, the substring will start at the beginning of *`original`*. If *`length`* is 0, the empty string will be returned.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN substring('hello', 1, 3), substring('hello', 2)
$$) as (sub_str1 agtype, sub_str2 agtype);

 sub_str1 | sub_str2
----------+----------
 "ell"    | "llo"
(1 row)
```

`rTrim(original variadic "any") returns agtype string`

`rTrim()` returns the original string with trailing whitespace removed. `rTrim(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN rTrim(' hello ')
$$) as (right_trimmed_str agtype);

 right_trimmed_str
-------------------
 " hello"
(1 row)
```

`lTrim(original variadic "any") returns agtype string`

`lTrim()` returns the original string with leading whitespace removed. `lTrim(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN lTrim(' hello ')
$$) as (left_trimmed_str agtype);

 left_trimmed_str
------------------
 "hello "
```

```
(1 row)
```

`trim(`*`original`* `variadic "any") returns agtype string`

`trim()` returns the original string with leading and trailing whitespace removed. `trim(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN trim(' hello ')
$$) as (trimmed_str agtype);

 trimmed_str
-------------
 "hello"
(1 row)
```

`toLower(`*`original`* `variadic "any") returns agtype string`

`toLower()` returns the original string in lowercase. `toLower(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN toLower('HELLO')
$$) as (lower_str agtype);

 lower_str
-----------
 "hello"
(1 row)
```

`toUpper(`*`original`* `variadic "any") returns agtype string`

`toUpper()` returns the original string in uppercase. `toUpper(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN toUpper('hello')
$$) as (upper_str agtype);

 upper_str
-----------
 "HELLO"
(1 row)
```

`reverse(`*`original`* `variadic "any") returns agtype string`

`reverse()` returns a string in which the order of all characters in the original string have been reversed. `reverse(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN reverse('hello')
$$) as (reverse_str agtype);

 reverse_str
-------------
 "olleh"
(1 row)
```

`toString(`*`expression`* `agtype) returns string`

`toString()` converts an `integer`, `float` or `boolean` value to a string. `toString(null)` returns `null`. If *`expression`* is a string, it will be returned unchanged.

```
SELECT *
FROM cypher('graph_name', $$
    RETURN toString(11.5),toString('a string'), toString(true)
$$) as (float_to_str agtype, str_to_str agtype, bool_to_string agtype);

 float_to_str | str_to_str | bool_to_string
--------------+------------+----------------
 "11.5"       | "a string" | "true"
(1 row)
```

H.1.27. Aggregation Functions

Functions that activate auto aggregation.

```
LOAD 'age';
SET search_path TO ag_catalog;

SELECT create_graph('graph_name');

SELECT * FROM cypher('graph_name', $$
    CREATE (a:Person {name: 'A', age: 13}),
    (b:Person {name: 'B', age: 33, eyes: 'blue'}),
    (c:Person {name: 'C', age: 44, eyes: 'blue'}),
    (d1:Person {name: 'D', eyes: 'brown'}),
    (d2:Person {name: 'D'}),
    (a)-[:KNOWS]->(b),
    (a)-[:KNOWS]->(c),
    (a)-[:KNOWS]->(d1),
    (b)-[:KNOWS]->(d2),
    (c)-[:KNOWS]->(d2)
$$) as (a agtype);
```

`min(`*expression* variadic "any"`) returns agtype`

`min()` returns the minimum value in a set of values. Any `null` values are excluded from the calculation. In a mixed set, any string value is always considered to be lower than any numeric value, and any list is always considered to be lower than any string. Lists are compared in dictionary order, i.e. list elements are compared pairwise in ascending order from the start of the list to the end. `min(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (v:Person)
    RETURN min(v.age)
$$) as (min_age agtype);

 min_age
---------
 13
(1 row)
```

The lowest of all the values in the property `age` is returned.

To clarify the following example, assume the next three commands are run first:

```
SELECT * FROM cypher('graph_name', $$
    CREATE (:min_test {val:'d'})
$$) as (result agtype);

SELECT * FROM cypher('graph_name', $$
    CREATE (:min_test {val:['a', 'b', 23]})
```

```
$$) as (result agtype);

SELECT * FROM cypher('graph_name', $$
    CREATE (:min_test {val:[1, 'b', 23]})
$$) as (result agtype);
```

The example below shows using `min()` with lists:

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (v:min_test)
    RETURN min(v.val)
$$) as (min_val agtype);

    min_val
----------------
 ["a", "b", 23]
(1 row)
```

The lowest of all the values in the set is returned (in this case, the list `["a", "b", 23]`), as the two lists are considered to be lower values than the string "d", and the string "a" is considered to be a lower value than the numerical value 1.

`max(`*expression* `variadic "any") returns agtype float`

`max()` returns the maximum value in a set of values. Any `null` values are excluded from the calculation. In a mixed set, any numeric value is always considered to be higher than any string value, and any string value is always considered to be higher than any list. Lists are compared in dictionary order, i.e. list elements are compared pairwise in ascending order from the start of the list to the end. `max(null)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n:Person)
    RETURN max(n.age)
$$) as (max_age agtype);

 max_age
---------
 44
(1 row)
```

The highest of all the values in the property `age` is returned.

`stDev(`*expression* `variadic "any") returns agtype float`

`stDev()` returns the standard deviation for the given value over a group. It uses a standard two-pass method, with N - 1 as the denominator, and should be used when taking a sample of the population for an unbiased estimate. When the standard deviation of the entire population is being calculated, `stDevP` should be used. Any `null` values are excluded from the calculation. `stDev(null)` returns 0.0 (zero).

```
SELECT *
FROM cypher('graph_name', $$
   MATCH (n:Person)
   RETURN stDev(n.age)
$$) as (stdev_age agtype);

     stdev_age
--------------------
 15.716233645501712
```

```
(1 row)
```

The standard deviation of the values in the property `age` is returned.

`stDevP(`*`expression`* `variadic "any") returns agtype float`

`stDev()` returns the standard deviation for the given value over a group. It uses a standard two-pass method, with N as the denominator, and should be used when calculating the standard deviation for an entire population. When the standard deviation of only a sample of the population is being calculated, `stDev` should be used. Any `null` values are excluded from the calculation. `stDevP(null)` returns 0.0 (zero).

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n:Person)
    RETURN stDevP(n.age)
$$) as (stdevp_age agtype);

     stdevp_age
--------------------
 12.832251036613439
(1 row)
```

The population standard deviation of the values in the property `age` is returned.

`percentileCont(`*`expression`* `agtype,` *`percentile`* `agtype) returns agtype float`

`percentileCont()` returns the percentile of the given value over a group, with a percentile from 0.0 to 1.0. It uses a linear interpolation method, calculating a weighted average between two values if the desired percentile lies between them. For nearest values using a rounding method, see `percentileDisc`. Any `null` values are excluded from the calculation. `percentileCont(null, percentile)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n:Person)
    RETURN percentileCont(n.age, 0.4)
$$) as (percentile_cont_age agtype);

 percentile_cont_age
---------------------
 29.0
(1 row)
```

The 40th percentile of the values in the property `age` is returned, calculated with a weighted average. In this case, 0.4 is the median, or 40th percentile.

`percentileDisc(`*`expression`* `agtype,` *`percentile`* `agtype) returns agtype float`

`percentileDisc()` returns the percentile of the given value over a group, with a percentile from 0.0 to 1.0. It uses a rounding method and calculates the nearest value to the percentile. For interpolated values, see `percentileCont`. Any `null` values are excluded from the calculation. `percentileDisc(null, percentile)` returns `null`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n:Person)
    RETURN percentileDisc(n.age, 0.5)
$$) as (percentile_disc_age agtype);

 percentile_disc_age
---------------------
```

```
 33.0
(1 row)
```

The 50th percentile of the values in the property `age` is returned.

`count(`*`expression`* `agtype) returns agtype integer`

`count()` returns the number of values or records, and appears in two variants:

- `count(*)` returns the number of matching records.
- `count(expr)` returns the number of non-null values returned by an expression.

`count(*)` includes records returning `null`. `count(expr)` ignores `null` values. `count(null)` returns 0 (zero). `count(*)` can be used to return the number of nodes; for example, the number of nodes connected to some node `n`.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'A'})-[]->(x)
    RETURN n.age, count(*)
$$) as (age agtype, number_of_people agtype);

 age | number_of_people
-----+------------------
 13  | 3
(1 row)
```

The `age` property of the start node `n` (with a name value of "A") and the number of nodes related to `n` are returned.

`count(*)` can be used to group and count relationship types, returning the number of relationships of each type.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'A'})-[r]->()
    RETURN type(r), count(*)
$$) as (label agtype, count agtype);

  label  | count
---------+-------
 "KNOWS" | 3
(1 row)
```

The relationship type and the number of relationships with that type are returned.

Instead of simply returning the number of records with `count(*)`, it may be more useful to return the actual number of values returned by an expression.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n {name: 'A'})-[]->(x)
    RETURN count(x)
$$) as (count agtype);

 count
-------
 3
(1 row)
```

The number of nodes connected to the start node `n` is returned.

`count(expression)` can be used to return the number of non-null values returned by the expression.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (n:Person)
    RETURN count(n.age)
$$) as (count agtype);

 count
-------
 3
(1 row)
```

The number of nodes with the label `Person` that have a non-null value for the `age` property is returned.

In the following example we are trying to find all our friends of friends, and count them. The first aggregate function, `count(DISTINCT friend_of_friend)`, will only count a `friend_of_friend` once, as *`DISTINCT`* removes the duplicates. The second aggregate function, `count(friend_of_friend)`, will consider the same `friend_of_friend` multiple times.

```
SELECT *
FROM cypher('graph_name', $$
    MATCH (me:Person)-[]->(friend:Person)-[]->(friend_of_friend:Person)
    WHERE me.name = 'A'
    RETURN count(DISTINCT friend_of_friend), count(friend_of_friend)
$$) as (friend_of_friends_distinct agtype, friend_of_friends agtype);

 friend_of_friends_distinct | friend_of_friends
----------------------------+-------------------
 1                          | 2
(1 row)
```

Both B and C know D and thus D will get counted twice when not using `DISTINCT`.

`avg(`*`expression`* `agtype) returns agtype integer`

`avg()` returns the average of a set of numeric values. Any `null` values are excluded from the calculation. `avg(null)` returns null.

```
SELECT *
FROM cypher('graph_name', $$
MATCH (n:Person)
RETURN avg(n.age)
$$) as (avg_age agtype);

 avg_age
---------
 30.0
(1 row)
```

The average of all the values in the property `age` is returned.

`sum(`*`expression`* `agtype) returns agtype float`

`sum()` returns the sum of a set of numeric values. Any `null` values are excluded from the calculation. `sum(null)` returns null.

```
SELECT *
FROM cypher('graph_name', $$
MATCH (n:Person)
RETURN sum(n.age)
$$) as (total_age agtype);

 total_age
```

```
-----------
 90
(1 row)
```

The sum of all the values in the property `age` is returned.

H.1.28. User-Defined Functions

Users may add custom functions to apache_age. When using Cypher functions, all function calls with a Cypher query use the default namespace of: `ag_catalog`. However, if a user wants to use a function outside of this namespace, they may do so by adding the namespace before the function name.

Syntax: *`namespace_name.function_name`*

```
SELECT *
FROM cypher('graph_name', $$
RETURN pg_catalog.sqrt(25)
$$) as (result agtype);

 result
--------
 25
(1 row)
```

H.1.29. apache_age Beyond Cypher

All queries so far have followed the same pattern: a `SELECT` clause followed by a single Cypher call in the `FROM` clause. However, a Cypher query can be used in many other ways. This section highlights some more advanced ways of using the Cypher call within a more complex SQL/Cypher Hybrid Query.

H.1.29.1. Using Cypher in a CTE Expression

There are no restrictions to using Cypher with CTEs (Common Table Expression).

```
WITH graph_query as (
    SELECT *
        FROM cypher('graph_name', $$
        MATCH (n)
        RETURN n.name, n.age
    $$) as (name agtype, age agtype)
)
SELECT * FROM graph_query;

 name       | age
------------+-----
 "Andres"   | 36
 "Tobias"   | 25
 "Peter"    | 35
(3 rows)
```

H.1.29.2. Using Cypher in a Join expression

A Cypher query can be part of a `JOIN` clause.

> **Note**
>
> Cypher queries using the `CREATE`, `SET`, `REMOVE` clauses cannot be used in SQL queries with joins, as they affect the Postgres Pro transaction system. One possible solution is to protect the query with CTEs.

```
SELECT id,
    graph_query.name = t.name as names_match,
    graph_query.age = t.age as ages_match
FROM schema_name.sql_person AS t
JOIN cypher('graph_name', $$
        MATCH (n:Person)
        RETURN n.name, n.age, id(n)
$$) as graph_query(name agtype, age agtype, id agtype)
ON t.person_id = graph_query.id;

 id | names_match | ages_match
 ---+-------------+------------
 1  | True        | True
 2  | False       | True
 3  | True        | False
(3 rows)
```

H.1.29.3. Cypher in SQL Expressions

Cypher cannot be used in an expression, the query must exists in the `FROM` clause of a query. However, if the Cypher query is placed in a subquery, it will behave as any SQL style query.

H.1.29.3.1. Using Cypher with `=`

When writing a Cypher query that is known to return one column and one row, the `=` comparison operator may be used.

```
SELECT t.name FROM schema_name.sql_person AS t
where t.name = (
    SELECT a
    FROM cypher('graph_name', $$
          MATCH (v)
        RETURN v.name
    $$) as (name varchar(50))
    ORDER BY name
    LIMIT 1);

   name   | age
----------+-----
 "Andres" | 36
(1 rows)
```

H.1.29.3.2. Working with Postgres Pro IN Clause

When writing a Cypher query that is known to return one column but may have multiple rows, the `IN` operator may be used.

```
SELECT t.name, t.age FROM schema_name.sql_person as t
where t.name in (
    SELECT *
    FROM cypher('graph_name', $$
        MATCH (v:Person)
        RETURN v.name
    $$) as (a agtype));

  name     | age
-----------+-----
 "Andres"  | 36
 "Tobias"  | 25
 "Peter"   | 35
```

```
(3 rows)
```

H.1.29.3.3. Working with Postgres Pro EXISTS Clause

When writing a Cypher query that may have more than one column and row returned, the `EXISTS` operator may be used.

```
SELECT t.name, t.age
FROM schema_name.sql_person as t
WHERE EXISTS (
    SELECT *
    FROM cypher('graph_name', $$
      MATCH (v:Person)
        RETURN v.name, v.age
    $$) as (name agtype, age agtype)
    WHERE name = t.name AND age = t.age
);

   name    | age
-----------+-----
 "Andres"  | 36
 "Tobias"  | 25
 "Peter"   | 35
(3 rows)
```

H.1.29.3.4. Querying Multiple Graphs

There is no restriction to the number of graphs an SQL statement can query. Users may query multiple graphs simultaneously.

```
SELECT graph_1.name, graph_1.age, graph_2.license_number
FROM cypher('graph_1', $$
    MATCH (v:Person)
    RETURN v.name, v.age
$$) as graph_1(col_1 agtype, col_2 agtype, col_3 agtype)
JOIN cypher('graph_2', $$
    MATCH (v:Doctor)
    RETURN v.name, v.license_number
$$) as graph_2(name agtype, license_number agtype)
ON graph_1.name = graph_2.name

   name    | age | license_number
-----------+-----+----------------
 "Andres"  | 36  | 1234567890
(1 rows)
```

H.1.29.4. Prepared Statements

Cypher can run a read query within a prepared statement. When using parameters with stored procedures, an SQL parameter must be placed in the Cypher function call. See The apache_age Query Format for details.

A Cypher parameter is in the format of a "$" followed by an identifier. Unlike Postgres Pro parameters, Cypher parameters start with a letter, followed by an alphanumeric string of arbitrary length. Example: *$parameter_name*

Preparing prepared statements in Cypher is an extension of Postgres Pro stored procedure system. Use the `PREPARE` clause to create a query with the Cypher function call in it. Do not place Postgres Pro style parameters in the Cypher query call, instead place Cypher parameters in the query and place a Postgres Pro parameter as the third argument in the Cypher function call.

```
PREPARE cypher_stored_procedure(agtype) AS
SELECT *
FROM cypher('expr', $$
    MATCH (v:Person)
    WHERE v.name = $name //Cypher parameter
    RETURN v
$$, $1) //An SQL Parameter must be placed in the Cypher function call
AS (v agtype);
```

When executing the prepared statement, place an `agtype map` with the parameter values where the Postgres Pro parameter in the Cypher function call is. The value must be an `agtype map` or an error will be thrown. Exclude the `$` for parameter names.

```
EXECUTE cypher_prepared_statement('{'name': 'Tobias'}');
```

H.1.29.5. PL/pgSQL Functions

Cypher commands can be run in PL/pgSQL functions without restriction.

```
SELECT *
FROM cypher('imdb', $$
    CREATE (toby:actor {name: 'Toby Maguire'}),
        (tom:actor {name: 'Tom Holland'}),
        (willam:actor {name: 'Willam Dafoe'}),
        (robert:actor {name: 'Robert Downey Jr'}),
        (spiderman:movie {title: 'Spiderman'}),
        (no_way_home:movie {title: 'Spiderman: No Way Home'}),
        (homecoming:movie {title: 'Spiderman: Homecoming'}),
        (ironman:movie {title: 'Ironman'}),
        (tropic_thunder:movie {title: 'Tropic Thunder'}),
        (toby)-[:acted_in {role: 'Peter Parker', alter_ego: 'Spiderman'}]->(spiderman),
        (willam)-[:acted_in {role: 'Norman Osborn', alter_ego: 'Green Goblin'}]-
>(spiderman),
        (toby)-[:acted_in {role: 'Toby Maguire'}]->(tropic_thunder),
        (robert)-[:acted_in {role: 'Kirk Lazarus'}]->(tropic_thunder),
        (robert)-[:acted_in {role: 'Tony Stark', alter_ego: 'Ironman'}]->(homecoming),
        (tom)-[:acted_in {role: 'Peter Parker', alter_ego: 'Spiderman'}]->(homecoming),
        (tom)-[:acted_in {role: 'Peter Parker', alter_ego: 'Spiderman'}]-
>(no_way_home),
        (toby)-[:acted_in {role: 'Peter Parker', alter_ego: 'Spiderman'}]-
>(no_way_home),
        (willam)-[:acted_in {role: 'Norman Osborn', alter_ego: 'Green Goblin'}]-
>(no_way_home)
$$) AS (a agtype);
```

The example of function creation is shown below.

```
CREATE OR REPLACE FUNCTION get_all_actor_names()
RETURNS TABLE(actor agtype)
LANGUAGE plpgsql
AS $BODY$
BEGIN
    LOAD 'age';
    SET search_path TO ag_catalog;

    RETURN QUERY
    SELECT *
    FROM ag_catalog.cypher('imdb', $$
        MATCH (v:actor)
        RETURN v.name
```

```
    $$) AS (a agtype);
END
$BODY$;
```

Execute the query:

```
SELECT * FROM get_all_actor_names();

       actor
--------------------
 "Toby Maguire"
 "Tom Holland"
 "Willam Dafoe"
 "Robert Downey Jr"
(4 rows)
```

> **Note**
>
> It is recommended to add the `LOAD 'age'` command and setting the `search_path` to the function declaration to ensure that the `CREATE FUNCTION` command works consistently.

H.1.29.5.1. Dynamic Cypher Example

```
CREATE OR REPLACE FUNCTION get_actors_who_played_role(role agtype)
RETURNS TABLE(actor agtype, movie agtype)
LANGUAGE plpgsql
AS $function$
DECLARE sql VARCHAR;
BEGIN
        load 'age';
        SET search_path TO ag_catalog;

        sql := format('
        SELECT *
        FROM cypher(''imdb'', $$
            MATCH (actor)-[:acted_in {role: %s}]->(movie:movie)
            RETURN actor.name, movie.title
        $$) AS (actor agtype, movie agtype);
    ', role);

        RETURN QUERY EXECUTE sql;

END
$function$;
```

```
SELECT * FROM get_actors_who_played_role('"Peter Parker"');

     actor      |          movie
----------------+--------------------------
 "Toby Maguire" | "Spiderman: No Way Home"
 "Toby Maguire" | "Spiderman"
 "Tom Holland"  | "Spiderman: Homecoming"
 "Tom Holland"  | "Spiderman: No Way Home"
(4 rows)
```

H.1.29.6. SQL in Cypher

apache_age does not support SQL being directly written in Cypher. However, with user-defined functions you can write SQL queries and call them in a Cypher command.

> **Note**
>
> This applies to void and scalar-value functions only. Set returning functions are not currently supported.

Create a function:

```
CREATE OR REPLACE FUNCTION public.get_event_year(name agtype) returns agtype AS $$
    SELECT year::agtype
    FROM history AS h
    WHERE h.event_name = name::text
    LIMIT 1;
$$ LANGUAGE sql;
```

```
SELECT * FROM cypher('graph_name', $$
    MATCH (e:event)
    WHERE e.year < public.get_event_year(e.name)
    RETURN e.name
$$) as (n agtype);

        n
--------------------
 "Apache Con 2021"
(1 row)
```

H.2. oracle_fdw — access to Oracle databases

The oracle_fdw module is a Postgres Pro extension that provides a Foreign Data Wrapper for easy and efficient access to Oracle databases, including pushdown of `WHERE` conditions and required columns as well as comprehensive `EXPLAIN` support.

H.2.1. Installation

The oracle_fdw extension is provided with Postgres Pro Enterprise as a separate pre-built package `oracle-fdw-ent-16` (for the detailed installation instructions, see Chapter 17). oracle_fdw requires Oracle Instant Client version 19.5.

For RPM-based systems (RHEL, SUSE, Red OS, ROSA, ALT Linux), download the `oracle-instantclient` RPM and install it using `rpm`. If you use a Debian-based system (Ubuntu, Astra Linux), you have to either convert the RPM package to a Debian package using alien, and then install it using dpkg, or download the ZIP archive of the client and extract the contents of the archive into the `/opt/oracle` directory.

Once you have Postgres Pro Enterprise installed, create the oracle_fdw extension:

```
CREATE EXTENSION oracle_fdw;
```

That will define the required functions and create a foreign data wrapper.

Note that the extension version as shown by the psql `\dx` command or the system catalog `pg_available_extensions` is *not* the installed version of oracle_fdw. To get the oracle_fdw version, use the `oracle_diag` function.

H.2.2. Internals

oracle_fdw sets the `MODULE` of the Oracle session to `postgres` and the `ACTION` to the backend process number. This can help identifying the Oracle session and allows you to trace it with `DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE`.

oracle_fdw uses Oracle array interface to avoid unnecessary client-server round-trips. The batch size can be configured with the prefetch table option and is set to 50 by default.

Rather than using a PLAN_TABLE to explain an Oracle query (which would require such a table to be created in the Oracle database), oracle_fdw uses execution plans stored in the library cache. For that, an Oracle query is *explicitly described*, which forces Oracle to parse the query. The hard part is to find the SQL_ID and CHILD_NUMBER of the statement in V$SQL because the SQL_TEXT column contains only the first 1000 bytes of the query. Therefore, oracle_fdw adds a comment to the query that contains a hash of the query text. This is used to search in V$SQL. The actual execution plan or cost information is retrieved from V$SQL_PLAN.

oracle_fdw uses transaction isolation level SERIALIZABLE on the Oracle side, which corresponds to Postgres Pro's REPEATABLE READ. This is necessary because a single Postgres Pro statement can lead to multiple Oracle queries (e.g. during a nested loop join) and the results need to be consistent. Unfortunately, the Oracle implementation of SERIALIZABLE has certain quirks; see the Problems section for more.

The Oracle transaction is committed immediately before the local transaction commits, so that a completed Postgres Pro transaction guarantees that the Oracle transaction has completed. However, there is a small chance that the Postgres Pro transaction cannot complete even though the Oracle transaction is committed. This cannot be avoided without using two-phase transactions and a transaction manager, which is beyond what a foreign data wrapper can reasonably provide. Prepared statements involving Oracle are not supported for the same reason.

H.2.3. Short Simple Example

This is an example how to use oracle_fdw. More detailed information is provided in the sections Options and Usage. You should also read the documentation on foreign data and the commands referenced there.

For the sake of this example, let's assume you can connect to Oracle as the operating system user postgres (or whoever starts the Postgres Pro server) with the following command:

```
sqlplus orauser/orapwd@//dbserver.mydomain.com:1521/ORADB
```

That means that the Oracle client and the environment are set up correctly. It is also assumed that oracle_fdw has been installed (see the Installation section).

We want to access a table defined like this:

```
SQL> DESCRIBE oratab
 Name                           Null?    Type
 ------------------------------ -------- ------------
 ID                             NOT NULL NUMBER(5)
 TEXT                                    VARCHAR2(30)
 FLOATING                       NOT NULL NUMBER(7,2)
```

Then configure oracle_fdw as a Postgres Pro superuser like this:

```
pgdb=# CREATE EXTENSION oracle_fdw;
pgdb=# CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw
          OPTIONS (dbserver '//dbserver.mydomain.com:1521/ORADB');
```

You can use other naming methods or local connections, see the description of dbserver below.

It is a good idea to use a superuser only where really necessary, so let's allow a normal user to use the foreign server (this is not required for the example to work but recommended):

```
pgdb=# GRANT USAGE ON FOREIGN SERVER oradb TO pguser;
```

Then you can connect to Postgres Pro as pguser and define the following:

```
pgdb=> CREATE USER MAPPING FOR pguser SERVER oradb
          OPTIONS (user 'orauser', password 'orapwd');
```

You can use external authentication to avoid storing Oracle passwords.

```
pgdb=> CREATE FOREIGN TABLE oratab (
```

```
    id        integer           OPTIONS (key 'true')  NOT NULL,
    text      character varying(30),
    floating  double precision  NOT NULL
) SERVER oradb OPTIONS (schema 'ORAUSER', table 'ORATAB');
```

Remember that the table and schema name (the latter is optional) must normally be in uppercase.

Now you can use the table like a regular Postgres Pro table.

H.2.4. Usage

H.2.4.1. Oracle Permissions

The Oracle user will need the `CREATE SESSION` privilege and the right to select from the table or view in question. Note that oracle_fdw accesses the Oracle table at query planning time to get its definition. This happens *before* permissions on the foreign table are checked. Consequently, you may receive an Oracle error if you try to access a foreign table on which you have no permissions in Postgres Pro. This is expected and no security problem.

For `EXPLAIN VERBOSE`, the user will also need `SELECT` privileges on `V$SQL` and `V$SQL_PLAN`.

H.2.4.2. Connections

oracle_fdw caches Oracle connections because it is expensive to create an Oracle session for each individual query. All connections are automatically closed when the Postgres Pro session ends.

The `close_connections` function can be used to close all cached Oracle connections. This can be useful for long-running sessions that do not access foreign tables all the time and want to avoid blocking the resources needed by an open Oracle connection. You cannot call this function inside a transaction that modifies Oracle data.

H.2.4.3. Columns

When you define a foreign table, the columns of the Oracle table are mapped to the Postgres Pro columns in the order of their definition.

oracle_fdw will only include those columns in the Oracle query that are actually needed by the Postgres Pro query.

The Postgres Pro table can have more or less columns than the Oracle table. If it has more columns, and these columns are used, you will receive a warning and NULL values will be returned.

If you want to `UPDATE` or `DELETE`, make sure that the `key` option is set on all columns that belong to the table's primary key. Failure to do so will result in errors.

H.2.4.4. Data Types

You must define the Postgres Pro columns with data types that oracle_fdw can translate (see the conversion table below). This restriction is only enforced if the column actually gets used, so you can define “dummy” columns for untranslatable data types as long as you don't access them (this trick only works with `SELECT`, not when modifying foreign data). If an Oracle value exceeds the size of the Postgres Pro column (e.g., the length of a `varchar` column or the maximal `integer` value), you will receive a runtime error.

These conversions are automatically handled by oracle_fdw:

```
Oracle type              | Possible PostgreSQL types
-------------------------+--------------------------------------------------
CHAR                     | char, varchar, text
NCHAR                    | char, varchar, text
VARCHAR                  | char, varchar, text
VARCHAR2                 | char, varchar, text, json
NVARCHAR2                | char, varchar, text
```

```
CLOB                       | char, varchar, text, json
LONG                       | char, varchar, text
RAW                        | uuid, bytea
BLOB                       | bytea
BFILE                      | bytea (read-only)
LONG RAW                   | bytea
NUMBER                     | numeric, float4, float8, char, varchar, text
NUMBER(n,m) with m<=0      | numeric, float4, float8, int2, int4, int8,
                           |    boolean, char, varchar, text
FLOAT                      | numeric, float4, float8, char, varchar, text
BINARY_FLOAT               | numeric, float4, float8, char, varchar, text
BINARY_DOUBLE              | numeric, float4, float8, char, varchar, text
DATE                       | date, timestamp, timestamptz, char, varchar, text
TIMESTAMP                  | date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH TIME ZONE   | date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH             | date, timestamp, timestamptz, char, varchar, text
   LOCAL TIME ZONE         |
INTERVAL YEAR TO MONTH     | interval, char, varchar, text
INTERVAL DAY TO SECOND     | interval, char, varchar, text
XMLTYPE                    | xml, char, varchar, text
MDSYS.SDO_GEOMETRY         | geometry (see "PostGIS support" below)
```

If a `NUMBER` is converted to a `boolean`, 0 means `false`, everything else `true`.

Inserting or updating `XMLTYPE` only works with values that do not exceed the maximum length of the `VARCHAR2` data type (4000 or 32767, depending on the `MAX_STRING_SIZE` parameter).

`NCLOB` is currently not supported because Oracle cannot automatically convert it to the client encoding.

If you want to convert `TIMESTAMP WITH LOCAL TIME ZONE` to `timestamp`, consider setting the `set_time-zone` option on the foreign server.

If you need conversions exceeding the above, define an appropriate view in Oracle or Postgres Pro.

H.2.4.5. `WHERE` Conditions and `ORDER BY` Clauses

Postgres Pro will use all applicable parts of the `WHERE` clause as a filter for the scan. The Oracle query that oracle_fdw constructs will contain a `WHERE` clause corresponding to these filter criteria whenever such a condition can safely be translated to Oracle SQL. This feature, also known as *push-down* of `WHERE` clauses, can greatly reduce the number of rows retrieved from Oracle and may enable Oracle's optimizer to choose a good plan for accessing the required tables.

Similarly, `ORDER BY` clauses will be pushed down to Oracle wherever possible. Note that no `ORDER BY` condition that sorts by a character string will be pushed down as the sort orders in Postgres Pro and Oracle cannot be guaranteed to be the same.

To make use of that, try to use simple conditions for the foreign table. Choose Postgres Pro column data types that correspond to Oracle's types because otherwise conditions cannot be translated.

The expressions `now()`, `transaction_timestamp()`, `current_timestamp`, `current_date`, and `local-timestamp` will be translated correctly.

The output of `EXPLAIN` will show the Oracle query used so you can see which conditions were translated to Oracle and how.

H.2.4.6. Joins Between Foreign Tables

oracle_fdw can push down joins to the Oracle server, that is, a join between two foreign tables will lead to a single Oracle query that performs the join on the Oracle side.

There are some restrictions when this can happen:

- Both tables must be defined on the same foreign server.
- Joins between three or more tables won't be pushed down.
- The join must be in a `SELECT` statement.
- oracle_fdw must be able to push down all join conditions and `WHERE` clauses.
- Cross joins without join conditions are not pushed down.
- If a join is pushed down, `ORDER BY` clauses will not be pushed down.

It is important that table statistics for both foreign tables have been collected with `ANALYZE` for Postgres Pro to determine the best join strategy.

H.2.4.7. Modifying Foreign Data

oracle_fdw supports `INSERT`, `UPDATE`, and `DELETE` on foreign tables. This is allowed by default (also in databases upgraded from an earlier Postgres Pro release) and can be disabled by setting the readonly table option.

For `UPDATE` and `DELETE` to work, the columns corresponding to the primary key columns of the Oracle table must have the key column option set. These columns are used to identify a foreign table row, so make sure that the option is set on *all* columns that belong to the primary key.

If you omit a foreign table column during `INSERT`, that column is set to the value defined in the `DEFAULT` clause on the Postgres Pro foreign table (or NULL if there is no `DEFAULT` clause). `DEFAULT` clauses on the corresponding Oracle columns are not used. If the Postgres Pro foreign table does not include all columns of the Oracle table, the Oracle `DEFAULT` clauses will be used for the columns not included in the foreign table definition.

The `RETURNING` clause on `INSERT`, `UPDATE` and `DELETE` is supported except for columns with Oracle data types `LONG` and `LONG RAW` (Oracle doesn't support these data types in the `RETURNING` clause).

Triggers on foreign tables are supported. Triggers defined with `AFTER` and `FOR EACH ROW` require that the foreign table has no columns with Oracle data type `LONG` or `LONG RAW`. This is because such triggers make use of the `RETURNING` clause mentioned above.

While modifying foreign data works, the performance is not particularly good, specifically when many rows are affected, because (owing to the way foreign data wrappers work) each row has to be treated individually.

Transactions are forwarded to Oracle so `BEGIN`, `COMMIT`, `ROLLBACK`, and `SAVEPOINT` work as expected. Prepared statements involving Oracle are not supported. See the Internals section for details.

Since oracle_fdw uses serialized transactions by default, it is possible that data modifying statements lead to a serialization failure:

```
ORA-08177: can't serialize access for this transaction
```

This can happen if concurrent transactions modify the table and gets more likely in long running transactions. Such errors can be identified by their `SQLSTATE` (40001). An application using oracle_fdw should retry transactions that fail with this error.

It is possible to use a different transaction isolation level, see Foreign Server Options for a discussion.

H.2.4.8. EXPLAIN

Postgres Pro's EXPLAIN will show the query that is actually issued to Oracle. `EXPLAIN VERBOSE` will show Oracle's execution plan (that will not work with Oracle server 9i or older, see Problems).

H.2.4.9. ANALYZE

You can use ANALYZE to gather statistics on a foreign table. This is supported by oracle_fdw.

Without statistics, Postgres Pro has no way to estimate the row count for queries on a foreign table, which can cause bad execution plans to be chosen.

Postgres Pro will *not* automatically gather statistics for foreign tables with the autovacuum daemon like it does for normal tables, so it is particularly important to run `ANALYZE` on foreign tables after creation and whenever the remote table has changed significantly.

Keep in mind that analyzing an Oracle foreign table will result in a full sequential table scan. You can use the table option sample_percent to speed this up by using only a sample of the Oracle table.

H.2.4.10. PostGIS Support

The data type `geometry` is only available when PostGIS is installed.

The only supported geometry types are `POINT`, `LINE`, `POLYGON`, `MULTIPOINT`, `MULTILINE`, and `MULTIPOLYGON` in two and three dimensions. Empty PostGIS geometries are not supported because they have no equivalent in Oracle Spatial.

NULL values for Oracle `SRID` will be converted to 0 and vice versa. For other conversions between Oracle `SRID` and PostGIS `SRID`, create a file `srid.map` in the Postgres Pro `share` directory. Each line of this file shall contain an Oracle `SRID` and the corresponding PostGIS `SRID`, separated by a whitespace. Keep the file small for good performance.

H.2.4.11. Support for `IMPORT FOREIGN SCHEMA`

IMPORT FOREIGN SCHEMA is supported to bulk import table definitions for all tables in an Oracle schema. In addition to the documentation of `IMPORT FOREIGN SCHEMA`, consider the following:

- `IMPORT FOREIGN SCHEMA` will create foreign tables for all objects found in `ALL_TAB_COLUMNS`. That includes tables, views and materialized views, but not synonyms.
- These are the supported options for `IMPORT FOREIGN SCHEMA`:
  - `case` controls case folding for table and column names during import.

    The possible values are:

    - `keep`: leave the names as they are in Oracle, usually in upper case.
    - `lower`: translate all table and column names to lower case.
    - `smart`: only translate names that are all upper case in Oracle (this is the default).
  - `collation` is the collation used for case folding for the `lower` and `smart` options of `case`.

    The default value is `default`, which is the database's default collation. Only collations in the `pg_catalog` schema are supported. See the `collname` values in the `pg_collation` catalog for a list of possible values.
  - `dblink` is the Oracle database link through which the schema is accessed.

    This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.
  - `readonly` sets the readonly option on all imported tables.
  - `skip_tables` (default `false`): don't import tables.
  - `skip_views` (default `false`): don't import views.
  - `skip_matviews` (default `false`): don't import materialized views.
  - `max_long` sets the max_long option on all imported tables.
  - `sample_percent` sets the sample_percent option on all imported tables.
  - `prefetch` sets the prefetch option on all imported tables.
  - `lob_prefetch` sets the lob_prefetch option on all imported tables.
  - `nchar` sets the nchar option on all imported tables.

- `set_timezone` sets the set_timezone option on all imported tables.

- The Oracle schema name must be written exactly as it is in Oracle, so normally in upper case. Since Postgres Pro translates names to lower case before processing, you must protect the schema name with double quotes (for example, `"SCOTT"`).
- Table names in the `LIMIT TO` or `EXCEPT` clause must be written as they will appear in Postgres Pro after the case folding described above.

Note that `IMPORT FOREIGN SCHEMA` does not work with Oracle server 8i; see the Problems section for details.

H.2.5. Reference

H.2.5.1. Objects Created by the Extension

`oracle_fdw_handler() RETURNS fdw_handler`
`oracle_fdw_validator(text[], oid) RETURNS void`

These functions are the handler and validator functions necessary to create a foreign data wrapper.

```
FOREIGN DATA WRAPPER oracle_fdw
  HANDLER oracle_fdw_handler
  VALIDATOR oracle_fdw_validator
```

The extension automatically creates a foreign data wrapper named `oracle_fdw`. Normally, that's all you need, and you can proceed to define foreign servers. You can create additional Oracle foreign data wrappers, for example, if you need to set the nls_lang option (you can alter the existing `oracle_fdw` wrapper, but all modifications will be lost after a dump/restore).

`oracle_close_connections() RETURNS void`

This function can be used to close all open Oracle connections in this session. See Usage for further description.

`oracle_diag(name DEFAULT NULL) RETURNS text`

This function is useful for diagnostic purposes only. It will return the versions of oracle_fdw, Postgres Pro server, and Oracle client. If called with no argument or NULL, it will additionally return the values of some environment variables used for establishing Oracle connections. If called with the name of a foreign server, it will additionally return the Oracle server version.

`oracle_execute(server name, stmt text) RETURNS void`

This function can be used to execute arbitrary SQL statements on the remote Oracle server. That will only work with statements that do not return results (typically DDL statements).

Be careful when using this function since it might disturb the transaction management of oracle_fdw. Remember that running a DDL statement in Oracle will issue an implicit `COMMIT`. You are best advised to use this function outside of multi-statement transactions.

H.2.5.2. Options

H.2.5.2.1. Foreign Data Wrapper Options

> **Important**
>
> If you modify the default foreign data wrapper `oracle_fdw`, any changes will be lost upon dump/restore. Create a new foreign data wrapper if you want the options to be persistent. The SQL script shipped with the software contains a `CREATE FOREIGN DATA WRAPPER` statement you can use.

`[nls_lang]`

Sets the `NLS_LANG` environment variable for Oracle to this value. `NLS_LANG` is in the form *`language_territory.charset`* (for example, `AMERICAN_AMERICA.AL32UTF8`). This must match your database encoding. When this value is not set, oracle_fdw will automatically do the right thing if it can and issue a warning if it cannot. Set this only if you know what you are doing. See the Problems section.

H.2.5.2.2. Foreign Server Options

`dbserver`

The Oracle database connection string for the remote database. This can be in any of the forms that Oracle supports as long as your Oracle client is configured accordingly. Set this to an empty string for local (`BEQUEATH`) connections.

`[isolation_level]`

The transaction isolation level to use at the Oracle database. The value can be `serializable`, `read_committed`, or `read_only`. The default is `serializable`.

Note that the Oracle table can be queried more than once during a single Postgres Pro statement (for example, during a nested loop join). To make sure that no inconsistencies caused by race conditions with concurrent transactions can occur, the transaction isolation level must guarantee read stability. This is only guaranteed with Oracle's `SERIALIZABLE` or `READ ONLY` isolation levels.

Unfortunately Oracle's implementation of `SERIALIZABLE` is rather bad and causes serialization errors (ORA-08177) in unexpected situations, like inserts into the table. Using `READ COMMITTED` transactions works around this problem, but *there is a risk of inconsistencies*. If you want to use it, check your execution plans if the foreign scan could be executed more than once.

`[nchar]`

Setting this option to `on` chooses a more expensive character conversion on the Oracle side. This is required if Oracle tables have `NCHAR` or `NVARCHAR2` columns that contain characters that cannot be represented in the Oracle database character set. The default is `off`.

Setting `nchar` to `on` has a noticable performance impact, and it causes ORA-01461 errors with `UPDATE` statements that set strings over 2000 bytes (or 16383 if you have `MAX_STRING_SIZE = EXTENDED`). This error seems to be an Oracle bug.

`[set_timezone]`

Setting this option to `on` sets the Oracle session time zone to the current value of the Postgres Pro parameter `timezone` when the connection to Oracle is made. This is only useful if you plan to use Oracle columns of type `TIMESTAMP WITH LOCAL TIME ZONE` and want to translate them to `timestamp without time zone` in Postgres Pro. The default is `off`.

Note that if you change `timezone` after the Oracle connection has been established, oracle_fdw will not change the Oracle session time zone. You can call `oracle_close_connections() RETURNS void` in that case so that a new connection is opened the next time you access a foreign table.

If Oracle does not recognize the time zone, connections will fail with an error like “ORA-01882: timezone region not found”.

In that case, either use a different `timezone` or leave the option set to `off` and set the environment variable `ORA_SDTZ` to an appropriate value in the environment of the Postgres Pro server.

H.2.5.2.3. User Mapping Options

`user`

The Oracle user name for the session. Set this to an empty string for *external authentication* if you don't want to store Oracle credentials in the Postgres Pro database (one simple way is to use an *external password store*).

`password`

The password for the Oracle user.

H.2.5.2.4. Foreign Table Options

`table`

The Oracle table name. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

To define a foreign table based on an arbitrary Oracle query, set this option to the query enclosed in parentheses:

```
OPTIONS (table '(SELECT col FROM tab WHERE val = ''string'')')
```

Do not set the schema option in this case. `INSERT`, `UPDATE`, and `DELETE` will work on foreign tables defined on simple queries; if you want to avoid that (or confusing Oracle error messages for more complicated queries), use the table option readonly.

`dblink`

The Oracle database link through which the table is accessed. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

`[schema]`

The table's schema (or owner). Useful to access tables that do not belong to the connecting Oracle user. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

`[max_long]`

The maximal length of any `LONG`, `LONG RAW`, and `XMLTYPE` columns in the Oracle table. Possible values are integers between 1 and 1073741823 (the maximal size of a `bytea` in Postgres Pro). This amount of memory will be allocated at least twice so large values will consume a lot of memory. If max_long is less than the length of the longest value retrieved, you will receive the error message “ORA-01406: fetched column value was truncated”. The default is `32767`.

`[readonly]`

`INSERT`, `UPDATE`, and `DELETE` are only allowed on tables where this option is not set to yes/on/true. The default is `false`.

`[sample_percent]`

This option only influences `ANALYZE` processing and can be useful to `ANALYZE` very large tables in a reasonable time.

The value must be between 0.000001 and 100 and defines the percentage of Oracle table blocks that will be randomly selected to calculate Postgres Pro table statistics. This is accomplished using the `SAMPLE BLOCK (x)` clause in Oracle. The default is `100`.

`ANALYZE` will fail with ORA-00933 for tables defined with Oracle queries and may fail with ORA-01446 for tables defined with complex Oracle views.

`[prefetch]`

Sets the number of rows that will be fetched with a single round-trip between Postgres Pro and Oracle during a foreign table scan. The value must be between 1 and 1000, where a value of zero disables prefetching. The default is `50`.

Higher values can speed up performance but will use more memory on the Postgres Pro server.

Note that there is no prefetching if the Oracle table contains columns of the type `MDSYS.SDO_GEOMETRY`.

`[lob_prefetch]`

Sets the number of bytes that are prefetched for `BLOB`, `CLOB`, and `BFILE` values. LOBs that exceed that size will require additional round trips between Postgres Pro and Oracle so setting this value bigger than the size of your typical LOB will be good for performance. Choosing bigger values for this option can allocate more memory on the server side but will boost performance for large LOBs. The default is `1048576`.

H.2.5.2.5. Column Options

`[key]`

If set to yes/on/true, the corresponding column on the foreign Oracle table is considered a primary key column. For `UPDATE` and `DELETE` to work, you must set this option on all columns that belong to the table's primary key. The default is `false`.

`[strip_zeros]`

If set to yes/on/true, ASCII 0 characters will be removed from the string during transfer. Such characters are valid in Oracle but not in Postgres Pro so they will cause an error when read by oracle_fdw. This option only makes sense for `character`, `character varying`, and `text` columns. The default is `false`.

H.2.6. Problems

H.2.6.1. Encoding

Characters stored in an Oracle database that cannot be converted to the Postgres Pro database encoding will silently be replaced by replacement characters, typically a normal or inverted question mark, by Oracle. You will get no warning or error messages.

If you use a Postgres Pro database encoding that Oracle does not know (currently these are `EUC_CN`, `EUC_KR`, `LATIN10`, `MULE_INTERNAL`, `WIN874`, and `SQL_ASCII`), non-ASCII characters cannot be translated correctly. You will get a warning in this case, and the characters will be replaced by replacement characters as described above.

You can set the nls_lang option of the foreign data wrapper to force a certain Oracle encoding, but the resulting characters will most likely be incorrect and lead to Postgres Pro error messages. This is probably only useful for `SQL_ASCII` encoding if you know what you are doing.

H.2.6.2. Limited Functionality in Old Oracle Versions

The definition of the Oracle system catalogs `V$SQL` and `V$SQL_PLAN` has changed with Oracle 10.1. Using `EXPLAIN VERBOSE` with older Oracle server versions will result in errors like:

```
ERROR:  error describing query: OCIStmtExecute failed to execute
        remote query for sql_id
DETAIL:  ORA-00904: "LAST_ACTIVE_TIME": invalid identifier
```

There is no plan to fix this, since Oracle 9i has been out of Extended Support since 2010 and the functionality is not essential.

`IMPORT FOREIGN SCHEMA` throws the following error with Oracle server 8i:

```
ERROR:  error importing foreign schema: OCIStmtExecute failed to execute
        column query
DETAIL:  ORA-00904: invalid column name
```

This is because the view `ALL_TAB_COLUMNS` lacks the column `CHAR_LENGTH`, which was added in Oracle 9i.

H.2.6.3. LDAP Libraries

The Oracle client shared library comes with its own LDAP client implementation conforming to *RFC 1823* so these functions have the same names as OpenLDAP's. This will lead to a name collision when the Postgres Pro server was configured `--with-ldap`.

The name collision will not be detected because oracle_fdw is loaded at runtime, but trouble will happen if anybody calls an LDAP function. Typically, OpenLDAP is loaded first so if Oracle calls an LDAP function (for example, if you use *directory naming* name resolution), the backend will crash. This can lead to messages like the following (seen on Linux) in the Postgres Pro server log:

```
../../../libraries/libldap/getentry.c:29: ldap_first_entry:
 Assertion `( (ld)->ld_options.ldo_valid == 0x2 )' failed.
```

Since Postgres Pro is built `--with-ldap`, it may work as long as you don't use any LDAP client functionality in Oracle. On some platforms, you can force Oracle's client shared library to be loaded before the Postgres Pro server is started (`LD_PRELOAD` on Linux). Then Oracle's LDAP functions should get used. In that case, Oracle may be able to use LDAP functionality, but using LDAP from Postgres Pro will crash the backend.

You cannot use LDAP functionality both in Postgres Pro and in Oracle.

H.2.6.4. Serialization Errors

In Oracle 11.2 or above, inserting the first row into a newly created Oracle table with oracle_fdw will lead to a serialization error.

This is because of an Oracle feature called *deferred segment creation*, which defers allocation of storage space for a new table until the first row is inserted. This causes a serialization failure with serializable transactions.

This is no serious problem; you can work around it by either ignoring that first error or creating the table with `SEGMENT CREATION IMMEDIATE`.

A much nastier problem is that concurrent inserts can sometimes cause serialization errors when an index page is split concurrently with a modifying serializable transaction.

Oracle claims that this is not a bug, and the suggested solution is to retry the transaction that got a serialization error.

H.2.6.5. Oracle Bugs

This is the list of Oracle bugs that affect or have affected oracle_fdw in the past.

Bug 2728408 can cause “ORA-8177 cannot serialize access for this transaction” even if no modification of remote data is attempted. It can occur with Oracle server 8.1.7.4 (install one-off patch 2728408) or Oracle server 9.2 (install Patch Set 9.2.0.4 or better).

Oracle client 21c is known not to work for `CLOB` columns (they appear empty). There is no ultimate proof that that is an Oracle bug, but other versions are working fine.

H.2.7. Authors

Laurenz Albe, with notable contributions from Vincent Mora of Oslandia and Tatsuro Yamada of the NTT OSS Center.

H.3. pg_hint_plan — control an execution plan with hinting phrases

H.3.1. Description

pg_hint_plan is a module that allows a user to control an execution plan with hinting phrases mentioned in comments of a special form.

Postgres Pro Enterprise uses a cost-based optimizer, which utilizes data statistics rather than static rules. The planner (optimizer) estimates costs of all possible execution plans for an SQL statement, then the execution plan with the lowest cost is executed. The planner makes every effort to select the best

execution plan, but it is not always perfect, since it does not take into account some of the data properties or correlations between columns.

pg_hint_plan makes it possible to tweak execution plans using so-called “hints”, which are simple descriptions added in SQL comments of a special form.

H.3.2. Overview

H.3.2.1. Basic Usage

pg_hint_plan reads hinting phrases in comments of a special form given with the target SQL statement. The special comment begins with the character sequence `/*+` and ends with `*/`. Hinting phrases consist of a hint name and following parameters enclosed in parentheses and delimited by whitespaces. Each hinting phrase can be delimited by new lines for readability.

In the example below, a hash join is selected as a joining method and `pgbench_accounts` is scanned by a sequential scan method.

```
 /*+
    HashJoin(a b)
    SeqScan(a)
  */
 EXPLAIN SELECT *
    FROM pgbench_branches b
    JOIN pgbench_accounts a ON b.bid = a.bid
    ORDER BY a.aid;
                                        QUERY PLAN
-------------------------------------------------------------------------------------
 Sort  (cost=31465.84..31715.84 rows=100000 width=197)
   Sort Key: a.aid
   ->  Hash Join  (cost=1.02..4016.02 rows=100000 width=197)
         Hash Cond: (a.bid = b.bid)
         ->  Seq Scan on pgbench_accounts a  (cost=0.00..2640.00 rows=100000 width=97)
         ->  Hash  (cost=1.01..1.01 rows=1 width=100)
               ->  Seq Scan on pgbench_branches b  (cost=0.00..1.01 rows=1 width=100)
(7 rows)
```

H.3.3. Hint Table

The above section mentions that hints are inserted in a comment of a special form. This is inconvenient if a query cannot be edited. For such cases, hints can be placed in a special table called `hint_plan.hints`, which looks as follows:

Column	Description
id	A unique number to identify a row for a hint. This column is filled automatically by sequence.
norm_query_string	A pattern that matches the query to be hinted. Constants in the query should be replaced with `?` as in the example below. Whitespaces are significant in the pattern.
application_name	A value of *`application_name`* of sessions to apply the hint to. The hint in the example below applies to sessions connected from psql. An empty string means sessions with any *`application_name`*.
hint	A hint phrase. This must be a series of hints excluding surrounding comment marks.

The following example shows how to work with the hint table.

```
INSERT INTO hint_plan.hints(norm_query_string, application_name, hints)
    VALUES (
        'EXPLAIN (COSTS false) SELECT * FROM t1 WHERE t1.id = ?;',
        '',
        'SeqScan(t1)');
INSERT 0 1
UPDATE hint_plan.hints
   SET hints = 'IndexScan(t1)'
 WHERE id = 1;
UPDATE 1
DELETE FROM hint_plan.hints
 WHERE id = 1;
DELETE 1
```

The hint table is owned by the extension owner and has the same default privileges as at the time of its creation, i.e. during `CREATE EXTENSION`. Hints in the hint table take priority over the hints specified in comments.

H.3.3.1. Types of Hints

Hinting phrases are classified into several types depending on the kind of object and how they can affect the planner. For more details, see Section H.3.9.

H.3.3.1.1. Hints for Scan Methods

Scan method hints enforce a specific scanning method on the target table. pg_hint_plan recognizes the target table by alias names, if any. They are, for example, `SeqScan` or `IndexScan`.

Scan hints work with ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables, and system catalogs. External (foreign) tables, table functions, `VALUES` clause, CTEs, views, and subqueries are not affected.

```
/*+
    SeqScan(t1)
    IndexScan(t2 t2_pkey)
 */
SELECT * FROM table1 t1 JOIN table table2 t2 ON (t1.key = t2.key);
```

H.3.3.1.2. Hints for Join Methods

Join method hints enforce join methods of the joins involving the specified tables.

This can affect joins only on ordinary tables. Inheritance tables, `UNLOGGED` tables, temporary tables, external (foreign) tables, system catalogs, table functions, `VALUES` command results, and CTEs are allowed to be in the parameter list. Joins on views and subqueries are not affected.

Join method hints are recommended to be used together with the `Leading` joining order hint because it guarantees that a joining order specified in the request will be executed.

The hint below prompts the `NestLoop(MergeJoin(c b) a)` joining structure:

```
/*+ Leading(((c b) a)) MergeJoin(c b) NestLoop(a b c) */ EXPLAIN(COSTS OFF, TIMING OFF,
 SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c WHERE a.f1 = b.f1 AND b.f1 = c.f1;

                           QUERY PLAN
-----------------------------------------------------------------
 Aggregate
   ->  Nested Loop
         ->  Merge Join
```

```
                Merge Cond: (c.f1 = b.f1)
                ->  Index Only Scan using t1_idx1 on t1 c
                ->  Materialize
                      ->  Index Only Scan using t1_idx1 on t1 b
          ->  Memoize
                Cache Key: b.f1
                Cache Mode: logical
                ->  Index Only Scan using t1_idx1 on t1 a
                      Index Cond: (f1 = b.f1)
```

H.3.3.1.3. Hint for Joining Order

The `Leading` hint enforces the joining order for two or more tables. There are two ways of enforcing. One is enforcing specific joining order but not restricting direction at each join level:

```
 /*+
     NestLoop(t1 t2)
     MergeJoin(t1 t2 t3)
     Leading(t1 t2 t3)
  */
 SELECT * FROM table1 t1
     JOIN table table2 t2 ON (t1.key = t2.key)
     JOIN table table3 t3 ON (t2.key = t3.key);
```

Another way also enforces join direction. When the above join order is specified, the join direction chosen by the planner (outer table — inner table) may be different from the expected one. If you want to change the join direction in such a situation, use the following format:

```
 /*+ Leading ((t1 (t2 t3))) * / SELECT ...
```

In this format, two elements enclosed in parentheses are nested, and within one parenthesis, the first element is the outer table, and the second element is the inner table.

Note that the `Leading` hint (just like join methods) does not operate together with GEQO if the number of tables specified in the request exceeds `geqo_threshold`.

Some extra examples of using the hint for joining order:

```
/*+ Leading(((c b) a)) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c WHERE a.f1 = b.f1 AND b.f1 = c.f1;
                          QUERY PLAN
---------------------------------------------------------------
 Aggregate
   ->  Hash Join
         Hash Cond: (b.f1 = a.f1)
         ->  Nested Loop
               ->  Index Only Scan using t1_idx1 on t1 c
               ->  Memoize
                     Cache Key: c.f1
                     Cache Mode: logical
                     ->  Index Only Scan using t1_idx1 on t1 b
                           Index Cond: (f1 = c.f1)
         ->  Hash
               ->  Seq Scan on t1 a
```

And an example below:

```
/*+ Leading(((d c) (b a))) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c, t1 d WHERE a.f1 = b.f1 AND b.f1 = c.f1 AND c.f1
 = d.f1;
```

```
                          QUERY PLAN
-------------------------------------------------------------
 Aggregate
   ->  Hash Join
         Hash Cond: (c.f1 = a.f1)
         ->  Nested Loop
               ->  Index Only Scan using t1_idx1 on t1 d
               ->  Memoize
                     Cache Key: d.f1
                     Cache Mode: logical
                     ->  Index Only Scan using t1_idx1 on t1 c
                           Index Cond: (f1 = d.f1)
         ->  Hash
               ->  Hash Join
                     Hash Cond: (b.f1 = a.f1)
                     ->  Seq Scan on t1 b
                     ->  Hash
                           ->  Seq Scan on t1 a
```

For details, see Section H.3.9.

H.3.3.1.4. Hints for Controlling Join Behavior

The “Memoize” hint allows the join to memoize the inner result, and the “NoMemoize” hint disallows it. In the example below, the “NoMemoize” hint prohibits the topmost hash join from memoizing the result of the table `a`.

```
/*+ NoMemoize(a b) */
EXPLAIN SELECT * FROM a, b WHERE a.val = b.val;
                             QUERY PLAN
--------------------------------------------------------------------
 Hash Join  (cost=270.00..1412.50 rows=100000 width=16)
   Hash Cond: (b.val = a.val)
   ->  Seq Scan on b  (cost=0.00..15.00 rows=1000 width=8)
   ->  Hash  (cost=145.00..145.00 rows=10000 width=8)
         ->  Seq Scan on a  (cost=0.00..145.00 rows=10000 width=8)
```

H.3.3.1.5. Hint for Row Number Correction

The `Rows` hint corrects the row number misestimation of joins that comes from restrictions in the planner. For example:

```
/*+ Rows(a b #10) */ SELECT... ; Sets rows of join result to 10
/*+ Rows(a b +10) */ SELECT... ; Increments row number by 10
/*+ Rows(a b -10) */ SELECT... ; Subtracts 10 from the row number.
/*+ Rows(a b *10) */ SELECT... ; Makes the number 10 times larger.
```

H.3.3.1.6. Hint for Parallel Plans

The `Parallel` hint enforces parallel execution configuration on scans. The third parameter specifies the strength of enforcement. “soft” means that pg_hint_plan only changes `max_parallel_workers_per_gather` and leaves all others to the planner. “hard” changes other planner parameters so as to forcibly apply the number. This can affect ordinary tables, inheritance parents, `UNLOGGED` tables, and system catalog. External tables, table functions, `VALUES` clause, CTEs, views, and subqueries are not affected. Internal tables of a view can be specified by its real name or its alias as the target object. The following example shows that the query is enforced differently on each table.

```
EXPLAIN /*+ Parallel(c1 3 hard) Parallel(c2 5 hard) */
      SELECT c2.a FROM c1 JOIN c2 ON (c1.a = c2.a);
                                  QUERY PLAN
------------------------------------------------------------------------------
 Hash Join  (cost=2.86..11406.38 rows=101 width=4)
```

```
   Hash Cond: (c1.a = c2.a)
   ->  Gather  (cost=0.00..7652.13 rows=1000101 width=4)
         Workers Planned: 3
         ->  Parallel Seq Scan on c1  (cost=0.00..7652.13 rows=322613 width=4)
   ->  Hash  (cost=1.59..1.59 rows=101 width=4)
         ->  Gather  (cost=0.00..1.59 rows=101 width=4)
               Workers Planned: 5
               ->  Parallel Seq Scan on c2  (cost=0.00..1.59 rows=59 width=4)

 EXPLAIN /*+ Parallel(tl 5 hard) */ SELECT sum(a) FROM tl;
                                    QUERY PLAN
-------------------------------------------------------------------------------
 Finalize Aggregate  (cost=693.02..693.03 rows=1 width=8)
   ->  Gather  (cost=693.00..693.01 rows=5 width=8)
         Workers Planned: 5
         ->  Partial Aggregate  (cost=693.00..693.01 rows=1 width=8)
               ->  Parallel Seq Scan on tl  (cost=0.00..643.00 rows=20000 width=4)
```

H.3.3.1.7. Hints for Stored Procedures

Hints can be used with stored procedures. Be careful when using hints, since they can be inherited.

```
CREATE OR REPLACE FUNCTION test_1() RETURNS bool AS $$
BEGIN
EXECUTE 'SELECT count(*) FROM t1 WHERE f1 < 2' ;
RETURN true;
END; $$ language plpgsql;

CREATE OR REPLACE FUNCTION test_2() RETURNS void AS $$
BEGIN
EXECUTE 'SELECT /*+ SET(enable_bitmapscan off)*/ test_1()' ;
END;
$$ language plpgsql;

 SELECT test_2();

    Query Text: SELECT count(*) FROM t1 WHERE f1 < 2
    Aggregate  (cost=18.00..18.01 rows=1 width=8) (actual time=0.511..0.512 rows=1
 loops=1)
      ->  Seq Scan on t1  (cost=0.00..17.50 rows=200 width=0) (actual time=0.105..0.457
 rows=200 loops=1)
            Filter: (f1 < 2)
            Rows Removed by Filter: 800
```

H.3.3.1.8. Hints for Prepared Statements

The pg_hint_plan extension allows using hints with prepared statements. Hints should be specified in the `PREPARE` statement and are ignored in the `EXECUTE` statement.

Below are a couple of sample queries. With the `IndexOnlyScan(t1)` hint:

```
/*+ IndexOnlyScan(t1) */ PREPARE stmt AS SELECT count(*) FROM t1 WHERE f1 < 2;

EXPLAIN EXECUTE stmt;
EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF) EXECUTE stmt;
                 QUERY PLAN
-----------------------------------------
 Aggregate
   ->  Index Only Scan using t1_idx1 on t1
         Index Cond: (f1 < 2)
```

And with the `BitmapScan(t1)` hint:

```
 /*+ BitmapScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF) EXECUTE stmt;
                QUERY PLAN
-------------------------------------------
 Aggregate
   ->  Index Only Scan using t1_idx1 on t1
         Index Cond: (f1 < 2)
```

H.3.3.1.9. Setting GUC Parameters During Planning

The `Set` hint changes GUC parameters during planning. The GUC parameter shown in Section 19.7.2 can have the expected effects on planning unless any other hint conflicts with the planner method configuration parameters. When multiple hints change the same GUC, the last hint takes effect. GUC parameters for pg_hint_plan are also settable by this hint, but it may not work as you expect.

```
 /*+ Set(random_page_cost 2.0) */
 SELECT * FROM table1 t1 WHERE key = 'value';
...
```

H.3.3.2. GUC Parameters for pg_hint_plan

GUC parameters described below affect the behavior of pg_hint_plan.

Table H.7. GUC Parameters

Parameter Name	Description	Default Value
pg_hint_plan.enable_hint	True enables pg_hint_plan.	on
pg_hint_plan.enable_hint_table	True enables hinting by table.	off
pg_hint_plan.parse_messages	Specifies the log level of hint parse error. Valid values are `error`, `warning`, `notice`, `info`, `log`, `debug`.	info
pg_hint_plan.debug_print	Controls debug print and verbosity. Valid values are `off`, `on`, `detailed`, and `verbose`.	off
pg_hint_plan.message_level	Specifies message level of debug print. Valid values are `error`, `warning`, `notice`, `info`, `log`, `debug`.	log
pg_hint_plan.hints_anywhere	If it is `on`, pg_hint_plan reads hints ignoring SQL syntax. This allows placing hints anywhere in the query but may cause false reads.	off

H.3.4. Installation

The pg_hint_plan extension is provided with Postgres Pro Enterprise as a separate pre-built package `pg-hint-plan-ent-16` (for the detailed installation instructions, see Chapter 17). Once you have Postgres Pro Enterprise installed, activate pg_hint_plan:

```
LOAD 'pg_hint_plan';
LOAD
```

You can also load it globally by adding `pg_hint_plan` to the shared_preload_libraries parameter in the `postgresql.conf` file.

```
shared_preload_libraries = 'pg_hint_plan'
```

For automatic loading for specific sessions, use `ALTER USER SET/ALTER DATABASE SET`.

pg_hint_plan does not require `CREATE EXTENSION`, but if you plan to use the hint table, create the extension and enable the `enable_hint_table` parameter:

```
CREATE EXTENSION pg_hint_plan;
SET pg_hint_plan.enable_hint_table TO on;
```

H.3.5. Details in Hinting

H.3.5.1. Syntax and Placement

pg_hint_plan reads hints only from the first block comment and immediately stops parsing of any characters except alphabetical characters, digits, spaces, underscores, commas, and parentheses. In the following example `HashJoin(a b)` and `SeqScan(a)` are parsed as hints, but `IndexScan(a)` and `MergeJoin(a b)` are not:

```
 /*+
    HashJoin(a b)
    SeqScan(a)
  */
 /*+ IndexScan(a) */
 EXPLAIN SELECT /*+ MergeJoin(a b) */ *
    FROM pgbench_branches b
    JOIN pgbench_accounts a ON b.bid = a.bid
    ORDER BY a.aid;
                                       QUERY PLAN
-------------------------------------------------------------------------------------
 Sort  (cost=31465.84..31715.84 rows=100000 width=197)
   Sort Key: a.aid
   ->  Hash Join  (cost=1.02..4016.02 rows=100000 width=197)
         Hash Cond: (a.bid = b.bid)
         ->  Seq Scan on pgbench_accounts a  (cost=0.00..2640.00 rows=100000 width=97)
         ->  Hash  (cost=1.01..1.01 rows=1 width=100)
               ->  Seq Scan on pgbench_branches b  (cost=0.00..1.01 rows=1 width=100)
(7 rows)
```

However, when the `hints_anywhere` parameter is `on`, pg_hint_plan reads hints from anywhere in the query so the following hint uses would be equivalent:

```
EXPLAIN /*+ SeqScan(t1)*/
SELECT * FROM table1 t1 WHERE a < 10;
                        QUERY PLAN
-----------------------------------------------------------
 Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)
   Filter: (a < 10)
(2 rows)

EXPLAIN
SELECT * FROM table1 t1 WHERE a < 10 AND '/*+SeqScan(t1)*/' <> '';
                        QUERY PLAN
-----------------------------------------------------------
 Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)
   Filter: (a < 10)
(2 rows)

EXPLAIN
```

```
SELECT * FROM table1 t1 WHERE a < 10 /*+SeqScan(t1)*/;
                        QUERY PLAN
-----------------------------------------------------------
 Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)
   Filter: (a < 10)
(2 rows)
```

H.3.5.2. Using with PL/pgSQL

pg_hint_plan works for queries in PL/pgSQL scripts with some restrictions.

- Hints affect only the following kinds of queries:
  - Queries that return one row (`SELECT`, `INSERT`, `UPDATE`, and `DELETE`)
  - Queries that return multiple rows (`RETURN QUERY`)
  - Dynamic SQL statements (`EXECUTE`)
  - Cursor open (`OPEN`)
  - Loop over result of a query (`FOR`)
- A hint comment should be placed after the first word in a query as in the example below, since preceding comments are not sent as a part of the query.

```
CREATE FUNCTION hints_func(integer) RETURNS integer AS $$
DECLARE
    id  integer;
    cnt integer;
BEGIN
    SELECT /*+ NoIndexScan(a) */ aid
        INTO id FROM pgbench_accounts a WHERE aid = $1;
    SELECT /*+ SeqScan(a) */ count(*)
        INTO cnt FROM pgbench_accounts a;
    RETURN id + cnt;
END;
$$ LANGUAGE plpgsql;
```

H.3.5.3. Letter Case in Object Names

Unlike the way PostgreSQL handles object names, pg_hint_plan compares bare object names in hints against the database internal object names in a case-sensitive manner. Therefore, an object name `TBL` in a hint matches only `"TBL"` in database and does not match any unquoted names like `TBL`, `tbl`, or `Tbl`.

H.3.5.4. Escaping Special Characters in Object Names

The objects defined as the hint parameter should be enclosed in double quotes if they include parentheses, double quotes, and whitespaces. The escaping rules are the same as in PostgreSQL.

H.3.5.5. Distinction Between Multiple Occurrences of a Table

pg_hint_plan identifies the target object by using aliases if they exist. This behavior is useful to point at a specific occurrence among multiple occurrences of one table.

```
 /*+ HashJoin(t1 t1) */
 EXPLAIN SELECT * FROM s1.t1
  JOIN public.t1 ON (s1.t1.id=public.t1.id);
 INFO:  hint syntax error at or near "HashJoin(t1 t1)"
 DETAIL:  Relation name "t1" is ambiguous.
...
 /*+ HashJoin(pt st) */
 EXPLAIN SELECT * FROM s1.t1 st
  JOIN public.t1 pt ON (st.id=pt.id);
```

```
                              QUERY PLAN
-----------------------------------------------------------------------
 Hash Join  (cost=64.00..1112.00 rows=28800 width=8)
   Hash Cond: (st.id = pt.id)
   ->  Seq Scan on t1 st  (cost=0.00..34.00 rows=2400 width=4)
   ->  Hash  (cost=34.00..34.00 rows=2400 width=4)
         ->  Seq Scan on t1 pt  (cost=0.00..34.00 rows=2400 width=4)
```

H.3.5.6. Underlying Tables of Views or Rules

Hints are not applicable on views themselves, but they can affect the queries within the view if the object names match the object names in the expanded query on the view. Assigning aliases to the tables in the view enables them to be manipulated from outside of the view.

```
 CREATE VIEW v1 AS SELECT * FROM t2;
 EXPLAIN /*+ HashJoin(t1 v1) */
          SELECT * FROM t1 JOIN v1 ON (c1.a = v1.a);
                           QUERY PLAN
-----------------------------------------------------------------------
 Hash Join  (cost=3.27..18181.67 rows=101 width=8)
   Hash Cond: (t1.a = t2.a)
   ->  Seq Scan on t1  (cost=0.00..14427.01 rows=1000101 width=4)
   ->  Hash  (cost=2.01..2.01 rows=101 width=4)
         ->  Seq Scan on t2  (cost=0.00..2.01 rows=101 width=4)
```

And one more example:

```
CREATE VIEW v1 AS SELECT count(*) FROM t1 WHERE f1 < 2;
/*+ IndexOnlyScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT * FROM v1;
                QUERY PLAN
-----------------------------------------
 Aggregate
   ->  Index Only Scan using t1_idx1 on t1
         Index Cond: (f1 < 2)
```

Be careful not to select tables with identical names in different views because these tables may become affected. To avoid this, try using unique aliases, for example, a combination of a view name and a table name:

```
/*+ SeqScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT * FROM v2;

             QUERY PLAN
-----------------------------------
 Nested Loop Semi Join
   Join Filter: ((count(*)) = t1.f1)
   ->  Aggregate
         ->  Seq Scan on t1 t1_1
               Filter: (f1 < 2)
   ->  Seq Scan on t1
```

H.3.5.7. Inheritance

Hints can point only at the parent of an inheritance tree, yet they affect all the tables in the inheritance tree. Hints pointing directly at children will not take effect.

H.3.5.8. Hinting in Multistatements

One multistatement can have exactly one hint comment and this hint affects all individual statements in the multistatement.

H.3.5.9. VALUES Expressions

`VALUES` expressions in the `FROM` clause are named as `*VALUES*` internally, so they are hintable if it is the only `VALUES` expression in a query. Two or more `VALUES` expressions in a query cannot be distinguished by looking at `EXPLAIN`, which makes the results ambiguous:

```
/*+ MergeJoin(*VALUES*_1 *VALUES*) */
      EXPLAIN SELECT * FROM (VALUES (1, 1), (2, 2)) v (a, b)
        JOIN (VALUES (1, 5), (2, 8), (3, 4)) w (a, c) ON v.a = w.a;
INFO:  pg_hint_plan: hint syntax error at or near "MergeJoin(*VALUES*_1 *VALUES*) "
DETAIL:  Relation name "*VALUES*" is ambiguous.
                               QUERY PLAN
------------------------------------------------------------------------
 Hash Join  (cost=0.05..0.12 rows=2 width=16)
   Hash Cond: ("*VALUES*_1".column1 = "*VALUES*".column1)
   ->  Values Scan on "*VALUES*_1"  (cost=0.00..0.04 rows=3 width=8)
   ->  Hash  (cost=0.03..0.03 rows=2 width=8)
         ->  Values Scan on "*VALUES*"  (cost=0.00..0.03 rows=2 width=8)
```

H.3.6. Subqueries

Subqueries in the following context can be hinted using the `ANY_subquery` name:

```
IN (SELECT ... {LIMIT | OFFSET ...} ...)
= ANY (SELECT ... {LIMIT | OFFSET ...} ...)
= SOME (SELECT ... {LIMIT | OFFSET ...} ...)
```

For these syntaxes, the planner internally assigns a name to the subquery when planning joins on tables including it, so join hints are applicable on such joins using the implicit name. For example:

```
 /*+ HashJoin(a1 ANY_subquery)*/
 EXPLAIN SELECT *
  FROM pgbench_accounts a1
 WHERE aid IN (SELECT bid FROM pgbench_accounts a2 LIMIT 10);
                                          QUERY PLAN

 ------------------------------------------------------------------------------------------
 Hash Semi Join  (cost=0.49..2903.00 rows=1 width=97)
    Hash Cond: (a1.aid = a2.bid)
    ->  Seq Scan on pgbench_accounts a1  (cost=0.00..2640.00 rows=100000 width=97)
    ->  Hash  (cost=0.36..0.36 rows=10 width=4)
          ->  Limit  (cost=0.00..0.26 rows=10 width=4)
                ->   Seq Scan on pgbench_accounts a2  (cost=0.00..2640.00 rows=100000
 width=4)
```

H.3.6.1. Using the `IndexOnlyScan` Hint

The index scan may be unexpectedly performed on another index when the index specified in the `IndexOnlyScan` hint cannot perform the index-only scan.

H.3.6.2. The `NoIndexScan` Hint

The `NoIndexScan` hint implies `NoIndexOnlyScan`.

H.3.6.3. Parallel Hints and `UNION`

A `UNION` can run in parallel only when all underlying subqueries are parallel-safe. Therefore, enforcing parallel on any of the subqueries allows a parallel-executable `UNION` to run in parallel. Meanwhile, the `Parallel` hint with zero workers prevents a scan from being executed in parallel.

H.3.6.4. Setting pg_hint_plan Parameters by Set Hints

pg_hint_plan parameters influence the behavior of the module, so some parameters do not work as expected:

- Hints to change `enable_hint`, `enable_hint_table` are ignored even though they are reported as "used hints" in debug logs.
- Setting `debug_print` and `message_level` starts working in the middle of the query processing.

H.3.7. Errors

pg_hint_plan stops parsing on any error and uses the already parsed hints. Typical errors are listed below.

H.3.7.1. Syntax Errors

Any syntactical errors or wrong hint names are reported as syntax errors. These errors are reported in the server log with the message level, which is specified by `pg_hint_plan.message_level` if `pg_hint_plan.debug_print` is on or above.

H.3.7.2. Incorrect Object Definitions

Hints with incorrect object definitions are simply ignored. This kind of error is reported as "Not Used Hint" in the server log.

H.3.7.3. Redundant or Conflicting Hints

The last hint will take effect in case of redundant or conflicting hints. This kind of error is reported as "Duplication Hint" in the server log under the same conditions as syntax errors.

H.3.7.4. Nested Comments

A hint comment cannot be recursive. If pg_hint_plan finds it, hint parsing is immediately stopped and all the hints already parsed are ignored.

H.3.8. Functional Limitations

H.3.8.1. Influences of Planner GUC Parameters

The planner does not try to consider the joining order for the `FROM` clause entries more than `from_collapse_limit`. In such cases pg_hint_plan cannot affect the joining order.

H.3.8.2. Hints Trying to Enforce Non-Executable Plans

The planner selects any executable plan when the enforced plan cannot be executed.

- FULL OUTER JOIN to use nested loop.
- Use of indexes that do not have columns used in quals.
- TID scans for queries without `ctid` conditions.

H.3.8.3. Hints from pgpro_result_cache

The planner and the pgpro_result_cache extension ignore each other's hints.

H.3.8.4. Queries in ECPG

ECPG removes comments from queries written as embedded SQL, so hints cannot be passed to it. The only exception is the `EXECUTE` command that passes the query string to the server as is. The hint table can be used in this case.

H.3.8.5. Query Identifiers

When compute_query_id is enabled, Postgres Pro generates a query ID, ignoring comments. Hence, queries with different hints, still written the same way, may compute the same query ID.

H.3.9. Available Hints

The available hints are listed below.

Table H.8. Hints List

Group	Format	Description
Scan method	SeqScan(*table*)	Forces the sequential scan on a table.
	TidScan(*table*)	Forces the TID scan on a table.
	IndexScan(*table*[*index*...])	Forces the index scan on a table. Restricts to specified indexes, if any.
	IndexOnlyScan(*table*[*index*...])	Forces the index-only scan on a table. Restricts to specified indexes, if any. The index scan may be used if the index-only scan is not available.
	BitmapScan(*table*[*index*...])	Forces the bitmap scan on a table. Restricts to specified indexes, if any.
	IndexScanRegexp(*table*[*POSIX regexp*...])	Forces the index scan on a table. Restricts to indexes that match the specified POSIX regular expression.
	IndexOnlyScanRegexp(*table*[*POSIX regexp*...])	Forces the index-only scan on a table. Restricts to indexes that match the specified POSIX regular expression.
	BitmapScanRegexp(*table*[*POSIX regexp*...])	Forces the bitmap scan on a table. Restricts to indexes that match the specified POSIX regular expression.
	NoSeqScan(*table*)	Forces the deactivation of the sequential scan on a table.
	NoTidScan(*table*)	Forces the deactivation of the TID scan on a table.
	NoIndexScan(*table*)	Forces the deactivation of the index scan and index-only scan on a table.
	NoIndexOnlyScan(*table*)	Forces the deactivation of the index-only scan on a table.
	NoBitmapScan(*table*)	Forces the deactivation of the bitmap scan on a table.
Join method	NestLoop(*table table*[*table*...])	Forces the nested loop for joins with specified tables.
	HashJoin(*table table*[*table*...])	Forces the hash join for joins with specified tables.

Group	Format	Description
	MergeJoin(*table table*[*table*...])	Forces the merge join for joins with specified tables.
	NoNestLoop(*table table*[*table*...])	Forces the deactivation of the nested loop for joins with specified tables.
	NoHashJoin(*table table*[*table*...])	Forces the deactivation of the hash join for joins with specified tables.
	NoMergeJoin(*table table*[*table*...])	Forces the deactivation of the merge join for joins with specified tables.
Join order	Leading(*table table*[*table*...])	Forces the join order as specified.
	Leading(*<join pair>*)	Forces the join order and directions as specified. A join pair is a pair of tables and/or other join pairs enclosed in parentheses, which can make a nested structure.
Control join behavior	Memoize(*table table*[*table*...])	Allows the topmost join of the joins involving the specified tables to memoize the inner result. Note that it does not enforce memoizing.
	NoMemoize(*table table*[*table*...])	Disallows the topmost join of the joins involving the specified tables to memoize the inner result.
Row number correction	Rows(*table table*[*table*...] *correction*)	Corrects row number of a result of the joins with the specified tables. The available correction methods are absolute (#<n>), addition (+<n>), subtraction (-<n>) and multiplication (*<n>). <n> should be a string that strtod() can read.
Parallel query configuration	Parallel(table <# of workers> [soft|hard])	Enforces or inhibits parallel execution of the specified table. <# of workers> is the desired number of parallel workers, where zero means inhibiting parallel execution. If the third parameter is `soft` (default), it only changes `max_parallel_workers_per_gather` and leaves everything else to the planner. The `hard` value enforces the specified number of workers.
GUC	Set(*GUC-parameter value*)	Sets the GUC parameter to the value while the planner is running.

EXPLAIN, SET, Chapter 19, Section 15.3

H.4. tds_fdw — connect to databases that use the TDS protocol

The `tds_fdw` module provides the foreign data wrapper tds_fdw, which can connect to databases that use the Tabular Data Stream (TDS) protocol, such as *Sybase* databases and *Microsoft SQL Server*.

This foreign data wrapper requires a library that implements the DB-Library interface, such as FreeTDS. This has been tested with FreeTDS, but not the proprietary implementations of DB-Library.

H.4.1. Limitations

Unlike `WHERE` and column pushdowns, which are supported when `match_column_names` is enabled, `JOIN` pushdown or write operations are not supported.

H.4.2. Installing tds_fdw

tds_fdw is provided with Postgres Pro Enterprise as a separate pre-built package `tds-fdw` (for the detailed installation instructions, see Chapter 17).

Install the `tds_fdw` extension using CREATE EXTENSION.

H.4.3. Configuring tds_fdw

H.4.3.1. Managing Character Sets/Encoding

Although many newer versions of the TDS protocol will only use USC-2 to communicate with the server, FreeTDS converts the UCS-2 to the client character set of your choice. To set the client character set, you can set `client charset` in `freetds.conf`. See *The `freetds.conf` File* and *Localization and TDS 7.0* for details.

You may need more configuring in case you get an error like this with Microsoft SQL Server when working with Unicode data:

```
NOTICE: DB-Library notice: Msg #: 4004, Msg state: 1, Msg: Unicode data in a Unicode-only collation or ntext data cannot be sent to clients using DB-Library (such as ISQL) or ODBC version 3.7 or earlier., Server: PILLIUM\SQLEXPRESS, Process: , Line: 1, Level: 16

ERROR: DB-Library error: DB #: 4004, DB Msg: General SQL Server error: Check messages from the SQL Server, OS #: -1, OS Msg: (null), Level: 16
```

In this case, you may have to manually set tds version in `freetds.conf` to 7.0 or higher. See *The `freetds.conf` File* and *Choosing a TDS protocol version* for details.

H.4.3.2. Configuring Encrypted Connections to MSSQL

This needs to be configured at the `freetds.conf`. See *The `freetds.conf` File* and under `freetds.conf settings`, look for encryption.

H.4.4. Usage

To prepare for database access using tds_fdw:

1. Create a foreign server object, using CREATE SERVER, to represent each database you want to connect to.
2. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server.

3. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each table you want to access.

H.4.4.1. Creating a Foreign Server

To create a foreign server, execute the CREATE SERVER command providing the following options:

`servername`

The servername, address or hostname of the foreign server. This can be a DSN, as specified in `freetds.conf`. See *FreeTDS name lookup* for details. You can set this option to a comma-separated list of server names, then each server is tried until the first connection succeeds. This is useful for automatic failover to a secondary server.

Required: Yes

Default: 127.0.0.1

`port`

The port of the foreign server. Instead of providing a port here, it can be specified in `freetds.conf` (if `servername` is a DSN).

Required: No

`database`

The database to connect to for this server

Required: No

`dbuse`

If `dbuse` is 0, tds_fdw will connect directly to `database`. If `dbuse` is not 0, tds_fdw will connect to the server's default database and then select the database by calling the DB-Library's `dbuse()` function. For Azure, `dbuse` currently needs to be set to 0.

Required: No

Default: 0

`language`

The language to use for messages and the locale to use for date formats. FreeTDS may default to U.S. English on most systems. You can probably also change this in `freetds.conf`. For information related to this for MS SQL Server, see *`SET LANGUAGE` in MS SQL Server*. For information related to Sybase ASE, see *Sybase ASE login options* and *`SET LANGUAGE` in Sybase ASE*.

Required: No

`character_set`

The client character set to use for the connection if you need to set this for some reason. For TDS protocol versions 7.0+, the connection always uses UCS-2, so this parameter does nothing in those cases. See *Localization and TDS 7.0* for details.

Required: No

`tds_version`

The version of the TDS protocol to use for this server. See *Choosing a TDS protocol version* and *History of TDS Versions* for details.

Required: No

`msg_handler`

The function used for the TDS message handler. Can be one of the following values:

- `notice`: TDS messages are turned into PostgreSQL notices
- `blackhole`: TDS messages are ignored

Required: No

Default: `blackhole`

`fdw_startup_cost`

A cost that is used in query planning to represent the overhead of using this foreign data wrapper.

Required: No

`fdw_tuple_cost`

A cost that is used in query planning to represent the overhead of fetching rows from this server.

Required: No

`sqlserver_ansi_mode`

A cost that is used to represent the overhead of fetching rows from this server used in query planning.

This option is supported for SQL Server only. Setting this to `true` will enable the following server-side settings after a successful connection to the foreign server:

- `CONCAT_NULLS_YIELDS_NULL ON`
- `ANSI_NULLS ON`
- `ANSI_WARNINGS ON`
- `QUOTED_IDENTIFIER ON`
- `ANSI_PADDING ON`
- `ANSI_NULL_DFLT_ON ON`

Those parameters in summary are comparable to the SQL Server option `ANSI_DEFAULTS`. In contrast, `sqlserver_ansi_mode` currently does not activate the following options:

- `CURSOR_CLOSE_ON_COMMIT`
- `IMPLICIT_TRANSACTIONS`

This follows the behavior of the native ODBC and OLEDB driver for SQL servers, which explicitly turn them off if not configured otherwise.

Required: No

Default: `false`

Some foreign table options can also be set at the server level. Those include:

- `use_remote_estimate`
- `row_estimate_method`

Example H.1. Create a Foreign Server

```
CREATE SERVER mssql_svr
    FOREIGN DATA WRAPPER tds_fdw
    OPTIONS (servername '127.0.0.1', port '1433', database 'tds_fdw_test', tds_version
 '7.1');
```

H.4.4.2. Creating a User Mapping

To create a user mapping, execute the CREATE USER MAPPING command providing the following options:

`username`

The username of the account on the foreign server

> **Important**
>
> If you are using Azure SQL, then your username for the foreign server will need to be in the format `username@servername`. If you only use the username, the authentication will fail.

Required: Yes

`password`

The password of the account on the foreign server

Required: Yes

Example H.2. Create a User Mapping

```
CREATE USER MAPPING FOR postgres
    SERVER mssql_svr
    OPTIONS (username 'sa', password '');
```

H.4.4.3. Creating a Foreign Table

To create a foreign table, execute the CREATE FOREIGN TABLE command providing the following options:

`query`

The query string to use to query the foreign table

Required: Yes (mutually exclusive with `table_name`)

`schema_name`

The schema that the table is in. The schema name can also be included in `table_name`.

Required: No

`table_name`

The table on the foreign server to query

Aliases: *table*

Required: Yes (mutually exclusive with `query`)

`match_column_names`

Match local columns with remote columns by comparing their table names instead of using the order in which they appear in the result set. Required for `WHERE` and column pushdowns.

Required: No

`use_remote_estimate`

Estimate the size of the table by performing some operation on the remote server, as defined by `row_estimate_method`, instead of using the local estimate, as defined by `local_tuple_estimate`

Required: No

`local_tuple_estimate`

A locally set estimate of the number of tuples that is used when `use_remote_estimate` is disabled

Required: No

`row_estimate_method`

Can be one of the following values:

- `execute`: Execute the query on the remote server and get the actual number of rows in the query
- `showplan_all`: Get the estimated number of rows using *MS SQL Server's* `SET SHOWPLAN_ALL`

Required: No

Default: `execute`

Example H.3. Create a Foreign Table

Using a `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    data varchar)
    SERVER mssql_svr
    OPTIONS (table_name 'dbo.mytable', row_estimate_method 'showplan_all');
```

Using a `schema_name` and `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    data varchar)
    SERVER mssql_svr
    OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method
 'showplan_all');
```

Using a `query` definition:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    data varchar)
    SERVER mssql_svr
    OPTIONS (query 'SELECT * FROM dbo.mytable', row_estimate_method 'showplan_all');
```

Setting a remote column name:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    col2 varchar OPTIONS (column_name 'data'))
    SERVER mssql_svr
    OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method
 'showplan_all');
```

H.4.4.4. Importing a Foreign Schema

To import a foreign schema, execute the IMPORT FOREIGN SCHEMA command providing the following options:

`import_default`

Controls whether column `DEFAULT` expressions are included in the definitions of foreign tables

Required: No

Default: false

`import_not_null`

Controls whether column `NOT NULL` constraints are included in the definitions of foreign tables

Required: No

Default: true

Example H.4. Import a Foreign Schema

```
IMPORT FOREIGN SCHEMA dbo
    EXCEPT (mssql_table)
    FROM SERVER mssql_svr
    INTO public
    OPTIONS (import_default 'true');
```

H.4.4.5. Setting Variables

To set a variable, execute the SET command.

The following variables are available:

`tds_fdw.show_before_row_memory_stats`

Print memory context stats to the Postgres Pro log before each row is fetched

`tds_fdw.show_after_row_memory_stats`

Print memory context stats to the Postgres Pro log after each row is fetched

`tds_fdw.show_finished_memory_stats`

Print memory context stats to the Postgres Pro log when a query is finished

Example H.5. Set a Variable

```
postgres=# SET tds_fdw.show_finished_memory_stats=1;
SET
```

H.4.4.6. Viewing the Query Issued on the Remote System

To view the query issued on the remote system, execute the EXPLAIN `[ VERBOSE ]` command.

H.4.5. Author

Geoff Montee

Appendix I. Additional Supplied Programs

This appendix, Appendix F, Appendix G, and Appendix H contain information regarding additional modules available in the Postgres Pro Enterprise distribution. See Appendix F, Appendix G, and Appendix H for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Enterprise installation and can be used like any other program.

I.1. Additional PostgreSQL/Postgres Pro Client Applications

This section covers PostgreSQL/Postgres Pro additional client applications included in the Postgres Pro Enterprise distribution. They can be run from anywhere, independent of where the database server resides. See also Postgres Pro Client Applications for information about client applications that are part of the core Postgres Pro Enterprise distribution. Note also the *ora2pgpro* utility, which is developed independently from the core project.

oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

Synopsis

`oid2name` [*option*...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 74.

> **Note**
>
> The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

`-f` *`filenode`*
`--filenode=`*`filenode`*

show info for table with filenode *`filenode`*.

`-i`
`--indexes`

include indexes and sequences in the listing.

`-o` *`oid`*
`--oid=`*`oid`*

show info for table with OID *`oid`*.

`-q`
`--quiet`

omit headers (useful for scripting).

`-s`
`--tablespaces`

show tablespace OIDs.

`-S`
`--system-objects`

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

`-t` *`tablename_pattern`*
`--table=`*`tablename_pattern`*

show info for table(s) matching *`tablename_pattern`*.

`-V`
`--version`

Print the oid2name version and exit.

`-x`
`--extended`

display more information about each object shown: tablespace name, schema name, and OID.

`-?`
`--help`

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d` *database*
`--dbname=`*database*

database to connect to.

`-h` *host*
`--host=`*host*

database server's host.

`-H` *host*

database server's host. Use of this parameter is *deprecated* as of Postgres Pro 12.

`-p` *port*
`--port=`*port*

database server's port.

`-U` *username*
`--username=`*username*

user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-S` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

Environment

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 37.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
    Oid  Database Name  Tablespace
----------------------------------
  17228       alvherre  pg_default
  17255     regression  pg_default
  17227      template0  pg_default
      1      template1  pg_default

$ oid2name -s
All tablespaces:
     Oid  Tablespace Name
-------------------------
    1663       pg_default
    1664        pg_global
  155151         fastdisk
  155152          bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
-rw-------  1 alvherre alvherre 136536064 sep 14 09:51 155173

Description

pg_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg_probackup supports PostgreSQL 11 or higher. In Postgres Pro Enterprise, pg_probackup provides S3 (Simple Storage Service) support for storing data in private clouds.

> **Note**
>
> pg_probackup provides complete processing of S3 interface logging.

- Overview
- Quick Start
- Installation and Setup
- Command-Line Reference
- Usage

Overview

As compared to other backup solutions, pg_probackup offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- S3 support for storing data in private clouds using MinIO object storage, Amazon S3 storage, and VK Cloud storage: provided in Postgres Pro Enterprise. Backup data is transferred to and from S3 without saving it in intermediate locations thus eliminating the need of having a large temporary storage.
- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from a backup by reusing valid unchanged pages available in PGDATA.
- CFS (Compressed File System) support for incremental backups in `DELTA`, `PAGE`, and `PTRACK` (the fastest) modes: provided in Postgres Pro Enterprise.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the `checkdb` command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backups from a standby: avoiding extra load on the primary by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (`PGDATA`), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.
- Catchup: cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with the primary.

To manage backup data, pg_probackup creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using pg_probackup, you can take full or incremental backups:

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to

taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. pg_probackup supports the following modes of incremental backups:

- DELTA backup. In this mode, pg_probackup reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
- PAGE backup. In this mode, pg_probackup scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in Setting up continuous WAL archiving to make PAGE backups.
- PTRACK backup. In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

> **Warning**
>
> After promoting a standby server to primary and switching timelines, take the first backup in **either FULL or DELTA mode**. Using other backup modes in this case may result in data corruption.

pg_probackup can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with pg_probackup must use one of the following *WAL delivery modes*:

- ARCHIVE. Such backups rely on continuous archiving to ensure consistent recovery. This is the default WAL delivery mode.
- STREAM. Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of continuous archiving having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *standalone*.

Limitations

pg_probackup currently has the following limitations:

- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the `backup` command must also be run by user `postgres`. To satisfy this requirement when taking backups in the remote mode using SSH, you must set `--remote-user` option to `postgres`.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the block_size and wal_block_size parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or libc/icu versions.
- Special limitations of pg_probackup in Postgres Pro Enterprise:
  - Incremental backup and restore for CFS tablespaces require ptrack 2.4.0 or higher.
  - Only the following commands can be launched in the remote mode: add-instance, backup, restore, delete, catchup, archive-push, and archive-get.

Quick Start

To quickly get started with pg_probackup, complete the steps below. This will set up FULL and DELTA backups in the remote mode and demonstrate some basic pg_probackup operations. In the following, these terms are used:

- `backup` — Postgres Pro role used to connect to the Postgres Pro cluster.
- `backupdb` — database used to connect to the Postgres Pro cluster.
- `backup_host` — host with the backup catalog.
- `backup_user` — user on `backup_host` running all pg_probackup operations.
- `/mnt/backups` — directory on `backup_host` where the backup catalog is stored.
- `postgres_host` — host with the Postgres Pro cluster.
- `postgres` — user on `postgres_host` under which Postgres Pro cluster processes are running.
- `/var/lib/pgpro/std-16/data` — Postgres Pro data directory on `postgres_host`.

Steps to perform:

1. Install pg_probackup on both `backup_host` and `postgres_host`.
2. Set up an SSH connection from `backup_host` to `postgres_host`.
3. Configure your database cluster for STREAM backups.
4. Initialize the backup catalog:

```
backup_user@backup_host:~$ pg_probackup init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initialized
```

5. Add a backup instance called `mydb` to the backup catalog:

```
backup_user@backup_host:~$ pg_probackup add-instance \
    -B /mnt/backups \
    -D /var/lib/pgpro/std-16/data \
    --instance=node \
    --remote-host=postgres_host \
    --remote-user=postgres
INFO: Instance 'node' successfully initialized
```

6. Make a FULL backup:

```
backup_user@backup_host:~$ pg_probackup backup \
    -B /mnt/backups \
    -b FULL \
    --instance=node \
    --stream \
    --compress-algorithm=zstd \
    --remote-host=postgres_host \
    --remote-user=postgres \
    -U backup \
    -d backupdb
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6J,
 backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: zstd,
 compress-level: 1
WARNING:  pgpro_edition() function is old-style and will be removed in future major
 release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
 block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/8000028, TLI: 1

INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/9000000 currentpos 0/9000000
INFO: backup->stop_lsn 0/8004E40
INFO: Getting the Recovery Time from WAL
```

```
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 1s
INFO: Validating backup SBOL6J
INFO: Backup SBOL6J data files are valid
INFO: Backup SBOL6J resident size: 53MB
INFO: Backup SBOL6J completed
```

7. List the backups of the instance:

```
backup_user@backup_host:~$ pg_probackup show \
        -B /mnt/backups \
        --instance=node
========================================================================================
 Instance  Version  ID      Recovery Time                  Mode  WAL Mode  TLI
 Time  Data   WAL  Zalg  Zratio  Start LSN  Stop LSN   Status
========================================================================================
 node      17       SBOL6J  2024-04-09 18:18:21.970314+03  FULL  STREAM    1/0
 4s  37MB  16MB  zstd    2.57  0/8000028  0/8004E40  OK
```

8. Make an incremental backup in the DELTA mode:

```
backup_user@backup_host:~$ pg_probackup backup \
    -B /mnt/backups \
    -b DELTA \
    --instance=node \
    --stream \
    --compress-algorithm=zstd \
    --remote-host=postgres_host \
    --remote-user=postgres \
    -U backup \
    -d backupdb
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6N,
 backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,
 compress-level: 1
WARNING:  pgpro_edition() function is old-style and will be removed in future major
 release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
 block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6J
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/9000028, TLI: 1
INFO: Parent Start LSN: 0/8000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/A000000 currentpos 0/A000000
INFO: backup->stop_lsn 0/9000190
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6N
INFO: Backup SBOL6N data files are valid
INFO: Backup SBOL6N resident size: 17MB
INFO: Backup SBOL6N completed
```

9. Add or modify some parameters in the pg_probackup configuration file, so that you do not have to specify them each time on the command line:

```
backup_user@backup_host:~$ pg_probackup set-config \
    -B /mnt/backups \
    --instance=node \
    --remote-host=postgres_host \
    --remote-user=postgres \
    -U backup \
    -d backupdb
```

10. Check the configuration of the instance:

```
backup_user@backup_host:~$ pg_probackup show-config \
    -B /mnt/backups \
    --instance=node
# Backup instance information
pgdata = /var/lib/pgpro/std-16/data
system-identifier = 7355886958826772732
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-format-console = PLAIN
log-format-file = PLAIN
log-filename = pg_probackup.log
log-rotation-size = 0TB
log-rotation-age = 0d
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
# Compression parameters
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host
remote-user = postgres
```

Note that the parameters not modified via `set-config` retain their default values.

11. Make another incremental backup in the DELTA mode, omitting the parameters stored in the configuration file earlier:

```
backup_user@backup_host:~$ pg_probackup backup \
    -B /mnt/backups \
    -b DELTA \
    --instance=node \
    --stream \
    --compress-algorithm=zstd
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6P,
 backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,
 compress-level: 1
WARNING:  pgpro_edition() function is old-style and will be removed in future major
 release, use pgpro_edition GUC variable instead.
```

```
INFO: This PostgreSQL instance was initialized with data block checksums. Data
 block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6N
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/A000028, TLI: 1
INFO: Parent Start LSN: 0/9000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/B000000 currentpos 0/B000000
INFO: backup->stop_lsn 0/A000190
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6P
INFO: Backup SBOL6P data files are valid
INFO: Backup SBOL6P resident size: 17MB
INFO: Backup SBOL6P completed
```

12. List the backups of the instance again:

```
backup_user@backup_host:~$ pg_probackup show \
    -B /mnt/backups \
    --instance=node
========================================================================================
 Instance  Version  ID      Recovery Time                  Mode   WAL Mode  TLI
 Time    Data   WAL  Zalg  Zratio  Start LSN  Stop LSN   Status
========================================================================================
 node      17       SBOL6P  2024-04-09 18:18:26.630175+03  DELTA  STREAM    1/1
 1s  1147kB  16MB  zstd    1.00  0/A000028  0/A000190  OK
 node      17       SBOL6N  2024-04-09 18:18:25.015713+03  DELTA  STREAM    1/1
 2s  1160kB  16MB  zstd    1.04  0/9000028  0/9000190  OK
 node      17       SBOL6J  2024-04-09 18:18:21.970314+03  FULL   STREAM    1/0
 4s    37MB  16MB  zstd    2.57  0/8000028  0/8004E40  OK
```

13. Restore the data from the latest available backup to an arbitrary location:

```
backup_user@backup_host:~$ pg_probackup restore \
    -B /mnt/backups \
    -D /var/lib/pgpro/std-16/staging-data \
    --instance=node
INFO: Validating parents for backup SBOL6P
INFO: Validating backup SBOL6J
INFO: Backup SBOL6J data files are valid
INFO: Validating backup SBOL6N
INFO: Backup SBOL6N data files are valid
INFO: Validating backup SBOL6P
INFO: Backup SBOL6P data files are valid
INFO: Backup SBOL6P WAL segments are valid
INFO: Backup SBOL6P is valid.
INFO: Restoring the database from the backup starting at 2024-04-09 18:18:25+03 on
 localhost
INFO: Start restoring backup files. PGDATA size: 112MB
INFO: Backup files are restored. Transferred bytes: 112MB, time elapsed: 2s
INFO: Restore incremental ratio (less is better): 100% (112MB/112MB)
INFO: Syncing restored files to disk
```

```
INFO: Restored backup files are synced, time elapsed: 1s
INFO: Restore of backup SBOL6P completed.
```

Installation and Setup

Once you have pg_probackup installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable pg_probackup backups.
- Optionally, configure SSH for running pg_probackup operations in the remote mode.
- Optionally, configure S3 for running pg_probackup connected to the S3 storage.

Initializing the Backup Catalog

pg_probackup stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where *backup_dir* is the path to the backup catalog. If the *backup_dir* already exists, it must be empty. Otherwise, pg_probackup returns an error.

The user launching pg_probackup must have full access to the *backup_dir* directory.

pg_probackup creates the *backup_dir* backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

Adding a New Backup Instance

pg_probackup can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
 [remote_options]
```

Where:

- *data_dir* is the data directory of the cluster you are going to back up. To set up and use pg_probackup, write access to this directory is required.
- *instance_name* is the name of the subdirectories that will store WAL and backup files for this cluster.
- remote_options are optional parameters that need to be specified only if *data_dir* is located on a remote system.

pg_probackup creates the *instance_name* subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/`*instance_name* directory contains the `pg_probackup.conf` configuration file that controls pg_probackup settings for this backup instance. If you run this command with the remote_options, the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune pg_probackup configuration, see the section called “Configuring pg_probackup”.

The user launching pg_probackup must have full access to *backup_dir* directory and at least read-only access to *data_dir* directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running pg_probackup commands.

> **Note**
>
> For Postgres Pro 11 or higher, it is recommended to use the group access feature, so that backups can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

Configuring the Database Cluster

Although pg_probackup can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

For security reasons, it is recommended to run the configuration SQL queries below in a separate database.

```
postgres=# CREATE DATABASE backupdb;
postgres=# \c backupdb
```

To perform a backup, the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server.

For Postgres Pro versions 11 — 14:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

For Postgres Pro 15 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_start(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_stop(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the pg_hba.conf file, allow connection to the database cluster on behalf of the `backup` role.

Since pg_probackup needs to read cluster files directly, pg_probackup must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (PGDATA) you are going to back up.

Depending on whether you plan to take standalone or archive backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run pg_probackup in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections Setting up STREAM Backups, Setting up continuous WAL archiving, Setting up Backup from Standby, Configuring the Remote Mode, Setting up Partial Restore, and Setting up PTRACK Backups.

Setting up STREAM Backups

To set up the cluster for STREAM backups, complete the following steps:

- If the backup role does not exist, create it with the REPLICATION privilege when Configuring the Database Cluster:

  ```
  CREATE ROLE backup WITH LOGIN REPLICATION;
  ```

- If the backup role already exists, grant it with the REPLICATION privilege:

  ```
  ALTER ROLE backup WITH REPLICATION;
  ```

- In the pg_hba.conf file, allow replication on behalf of the backup role.
- Make sure the parameter max_wal_senders is set high enough to leave at least one session available for the backup process.
- Set the parameter wal_level to be higher than minimal.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section Setting up continuous WAL archiving.

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the STREAM WAL mode.

> **Note**
>
> If you are planning to rely on .pgpass for authentication when running backup in STREAM mode, then .pgpass must contain credentials for replication database, used to establish connection via replication protocol. Example: pghost:5432:replication:backup_user:my_strong_password

Setting up Continuous WAL Archiving

Making backups in the PAGE backup mode, performing PITR and making backups with the ARCHIVE WAL delivery mode require continuous WAL archiving to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the wal_level parameter is higher than minimal.
- If you are configuring archiving on the primary, archive_mode must be set to on or always. To perform archiving on a standby, set this parameter to always.
- Set the archive_command parameter, as follows:

  ```
  archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --
  instance=instance_name --wal-file-name=%f [remote_options]'
  ```

where *install_dir* is the installation directory of the pg_probackup version you are going to use, *backup_dir* and *instance_name* refer to the already initialized backup catalog instance for this database cluster, and remote_options only need to be specified to archive WAL on a remote host. For details about all possible archive-push parameters, see the section archive-push.

Once these steps are complete, you can start making backups in the ARCHIVE WAL mode, backups in the PAGE backup mode, as well as perform PITR.

You can view the current state of the WAL archive using the show command. For details, see the section called “Viewing WAL Archive Information”.

If you are planning to make PAGE backups and/or backups with ARCHIVE WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the archive_timeout Postgres Pro parameter **on the primary**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to a standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

> **Note**
>
> Instead of using the archive-push command provided by pg_probackup, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into *backup_dir*`/wal/`*instance_name* directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

> **Note**
>
> Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the pg_receivewal utility. In this case, pg_receivewal `-D` *directory* option should point to *backup_dir*`/wal/`*instance_name* directory. pg_probackup supports WAL compression that can be done by pg_receivewal. “Zero Data Loss” archive strategy can be achieved only by using pg_receivewal.

Setting up Backups from a Standby

pg_probackup can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the hot_standby parameter to `on`.
- On the primary server, set the full_page_writes parameter to `on`.
- To perform standalone backups on a standby, complete all the steps in section Setting up STREAM Backups.
- To perform archive backups on a standby, complete all steps in section Setting up continuous WAL archiving.

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backups from a standby server have the following limitations:

- If a standby is promoted to a primary during the backup process, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the primary, and not to use tools like pg_compresslog as archive_command to remove full-page writes from WAL files.

Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the amcheck or *amcheck_next* extension **in every database** of the cluster:

  ```
  CREATE EXTENSION amcheck;
  ```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role only in the database **used for connection** to Postgres Pro server:

  ```
  GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
  ```

Configuring the Remote Mode

pg_probackup supports the remote mode that allows you to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

Set up SSH

If you are going to use pg_probackup in remote mode via SSH, complete the following steps:

1. Install pg_probackup on both systems: `backup_host` and `postgres_host`.
2. For communication between the hosts set up a passwordless SSH connection between the `backup_user` user on `backup_host` and the `postgres` user on `postgres_host`:

   ```
   backup_user@backup_host:~$ ssh-copy-id postgres@postgres_host
   ```

   Where:

   - `backup_host` is the system with *backup catalog*.
   - `postgres_host` is the system with the Postgres Pro cluster.
   - `backup_user` is the OS user on `backup_host` used to run pg_probackup.
   - `postgres` is the user on `postgres_host` under which Postgres Pro cluster processes are running. For Postgres Pro 11 or higher a more secure approach can be used thanks to group access feature.
3. If you are going to rely on continuous WAL archiving, set up a passwordless SSH connection between the `postgres` user on `postgres_host` and the `backup` user on `backup_host`:

   ```
   postgres@postgres_host:~$ ssh-copy-id backup_user@backup_host
   ```
4. Make sure pg_probackup on `postgres_host` can be located when a connection via SSH is made. For example, for Bash, you can modify `PATH` in `~/.bashrc` of the `postgres` user (above the line in `bashrc` that exits the script for non-interactive shells). Alternatively, for pg_probackup commands, specify the path to the directory containing the pg_probackup binary on `postgres_host` via the --remote-path option.

pg_probackup in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: add-instance, backup, restore, delete, catchup, archive-push, and archive-get.
- Operating in remote mode requires pg_probackup binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main pg_probackup process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j`/`--threads` setting.

- The main pg_probackup process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on *backup_host* and connects to *postgres_host*, but in case of `archive-push` and `archive-get` commands the main process is started on *postgres_host* and connects to *backup_host*.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main pg_probackup process, which exits with an error.
- Compression is always done on *postgres_host*, while decompression is always done on *backup_host*.

> **Note**
>
> You can impose *additional restrictions* on SSH settings to protect the system in the event of account compromise.

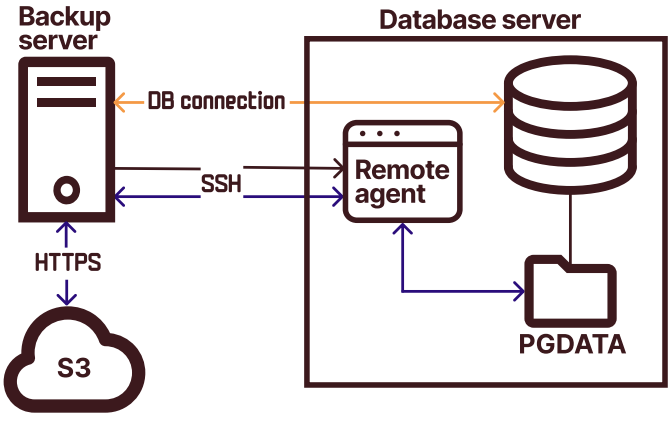
> **Note**
>
> Setting the number of threads (`-j`/`--threads` option) to a value greater than 10 for pg_probackup working in the remote mode via SSH may result in the actual number of SSH connections exceeding the maximum allowed number of simultaneous SSH connections on the remote server and consequently lead to an "ERROR: Agent error: kex_exchange_identification: Connection closed by remote host" error. To correct the error, either reduce the number of pg_probackup threads or adjust the value of `MaxStartups` configuration parameter of the remote SSH server. If SSH is set up as a xinetd service on the remote server, adjust the value of the xinetd `per_source` configuration parameter rather than `MaxStartups`.

Configuring S3 Connectivity

pg_probackup supports S3 interface for storing backups. Backup data is transferred to and from S3 without saving it in intermediate locations thus eliminating the need of having a large temporary storage.

An example configuration with a remote agent and a cloud storage (S3) is shown in Figure I.1.

Figure I.1. pg_probackup setup with a remote agent and S3



In this figure, the following logical components are shown:

Backup server

A server where the main process of pg_probackup runs and where local backups are stored.

Database server

A server with a database instance that needs to be backed up or restored.

Remote agent

A secondary pg_probackup process running on the database server. Only applicable to the remote mode.

Cloud storage

A cloud storage for backups.

Set up Access to S3 Storage

If you are going to use pg_probackup with S3 interface, complete the following steps:

- Create a bucket with a unique and meaningful name in the S3 storage for you future backups.
- Create ACCESS_KEY and SECRET_ACCESS_KEY tokens to be used for secure connectivity instead of your username and password.
- For communication between pg_probackup and S3 server, set values of environment variables corresponding to your S3 server. For example:

```
export PG_PROBACKUP_S3_HOST=127.0.0.1
export PG_PROBACKUP_S3_PORT=9000
export PG_PROBACKUP_S3_REGION=ru-msk
export PG_PROBACKUP_S3_BUCKET_NAME=test1
export PG_PROBACKUP_S3_ACCESS_KEY=admin
export PG_PROBACKUP_S3_SECRET_ACCESS_KEY=password
export PG_PROBACKUP_S3_HTTPS=ON
```

Alternatively, you can provide S3 server settings in the S3 configuration file (see the `--s3-config-file` option in the section S3 Options for details).

It makes sense to specify S3 server settings if `--s3=minio`, as described in the section S3 Options.

The following environment variables can be specified:

`PG_PROBACKUP_S3_HOST`

Address or list of addresses of the S3 server. A list of one or several semicolon-delimited addresses. Do not add a semicolon after the last address in the list. Each address can include the port number, separated by a colon. If the port number is not specified, the value of `PG_PROBACKUP_S3_PORT` is assumed. Do not add a colon if the port number is not specified.

For example:

```
export PG_PROBACKUP_S3_PORT=80
export PG_PROBACKUP_S3_HOST="127.0.0.1:9000;10.4.13.56:443;172.17.0.1"
```

In this example, for the “127.0.0.1” address, the port 9000 is explicitly specified, for “10.4.13.56”, the port 443 is specified, while for the “172.17.0.1” address, port 80, specified through `PG_PROBACKUP_S3_PORT`, will be used.

If any of the specified addresses gets unavailable while pg_probackup is in operation, requests to the S3 storage are distribited between the rest of the specified addresses. That is, when several addresses are specified, pg_probackup performs load balancing of S3 requests.

`PG_PROBACKUP_S3_PORT`

The port of the S3 server.

`PG_PROBACKUP_S3_REGION`

The region of the S3 server.

`PG_PROBACKUP_S3_BUCKET_NAME`

The name of the bucket on the S3 server.

`PG_PROBACKUP_S3_ACCESS_KEY`
`PG_PROBACKUP_S3_SECRET_ACCESS_KEY`

Secure tokens on the S3 server.

`PG_PROBACKUP_S3_HTTPS`

The protocol to be used. Possible values:

- `ON` or `HTTPS` — use HTTPS
- Other than `ON` or `HTTPS` — use HTTP

`PG_PROBACKUP_S3_BUFFER_SIZE`

The size of the read/write buffer for communicating with S3, in MiB. The default is `16`.

`PG_PROBACKUP_S3_RETRIES`

The maximum number of attempts to execute an S3 request in case of failures. The default is `3`.

`PG_PROBACKUP_S3_TIMEOUT`

The maximum amount of time to execute an HTTP request to the S3 server, in seconds. The default is `300`.

`PG_PROBACKUP_S3_IGNORE_CERT_VER`

Don't verify the certificate host and peer. The default is `ON`.

`PG_PROBACKUP_S3_CA_CERTIFICATE`

Specify the path to file with trust Certificate Authority (CA) bundle.

`PG_PROBACKUP_S3_CA_PATH`

Specify the directory with trust CA certificates.

`PG_PROBACKUP_S3_CLIENT_CERT`

Setup SSL client certificate.

`PG_PROBACKUP_S3_CLIENT_KEY`

Setup private key file for TLS and SSL client certificate.

Setting up PTRACK Backups

> **Note**
>
> PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps.

> **Note**
>
> The permissions required for the role that will perform PTRACK backups (the `backup` role in the examples below) are listed in the section called “Configuring the Database Cluster”. The role must have permissions only in the database used for connection to the Postgres Pro server.

For Postgres Pro 11 or higher:

1. Create PTRACK extension in the database *used for connection* to the Postgres Pro server:

   ```
   CREATE EXTENSION ptrack;
   ```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

   For optimal performance, it is recommended to set `ptrack.map_size` to *`N / 1024`*, where *`N`* is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

> **Note**
>
> If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

Usage

Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance=instance_name -b backup_mode
```

Where *`backup_mode`* can take one of the following values: `FULL`, `DELTA`, `PAGE`, and `PTRACK`.

When restoring a cluster from an incremental backup, pg_probackup relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. Thus, to perform incremental backups, it is necessary to have the last parent full backup with the status `OK` or `DONE` in the directory. If the parent full backup has the `MERGING` or `MERGED` status, an incremental backup cannot be performed.

For example, if merge has already been launched with a single full backup, an attempt to perform an incremental backup will end with the following messages:

```
WARNING: Valid full backup on current timeline 1 is not found, trying to look up on
 previous timelines
WARNING: Cannot find valid backup on previous timelines
ERROR: Create new full backup before an incremental one
```

ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL
```

ARCHIVE backups rely on continuous archiving to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, pg_probackup ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in *`backup_dir`*`/wal/`*`instance_name`* directory. pg_probackup also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During backup pg_probackup streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to *backup_dir*`/backups/`*instance_name*`/`*backup_id*`/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, pg_probackup also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using continuous archiving, STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

Page Validation

If data_checksums are enabled in the database cluster, pg_probackup uses this information to check correctness of data files during backup. While reading each page, pg_probackup checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that pg_probackup reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 300 times. In this case, the backup is aborted.

Even if data checksums are not enabled, pg_probackup always performs sanity checks for page headers.

External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your *instance_name* instance that will be stored under the *backup_dir* directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=/
etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=C:
\dir1;C:\dir2
```

pg_probackup recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the set-config command with the `--external-dirs` option.

Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance=instance_name]] [-D data_dir]
 [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar page validation is performed automatically while a backup is taken by pg_probackup. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using pg_probackup at all.

To perform cluster verification, pg_probackup needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for pg_probackup to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide connection options and *`data_dir`* via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions amcheck and *amcheck_next* provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the checkdb command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit *backup_dir* and *data_dir* options, only connection options are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

Validating a Backup

pg_probackup calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

> **Note**
>
> The backup validation includes checking checksums for CFS files.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running backup and restore commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the validate command with the exact recovery target options you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name --recovery-target-xid=4242
```

If validation completes successfully, pg_probackup displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify *backup_id* via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If *backup_id* is specified with recovery target options, the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `SBOL6P` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name -i SBOL6P --recovery-
target-time="2024-04-10 18:18:26+03"
```

If you specify the *backup_id* of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

Restoring a Cluster

To restore the database cluster from a backup, run the restore command with at least the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -i backup_id
```

Where:

- *backup_dir* is the backup catalog that stores all backup files and meta information.
- *instance_name* is the backup instance for the cluster to be restored.
- *backup_id* specifies the backup to restore the cluster from. If you omit this option, pg_probackup uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, pg_probackup automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore ARCHIVE backups, perform PITR, or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, pg_probackup creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the primary_conninfo parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, pg_probackup writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a STREAM backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For ARCHIVE backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the recovery target options with the `restore` command, as explained in the section called “Performing Point-in-Time (PITR) Recovery”.

If the cluster to restore contains tablespaces, pg_probackup restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping`/`-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping`/`-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -j 4 -
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in the section called “Using pg_probackup in the Remote Mode”.

> **Note**
>
> By default, the restore command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using incremental restore options with the restore command.

To restore the database cluster from a backup in incremental mode, run the restore command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -
I incremental_mode
```

Where *incremental_mode* can take one of the following values:

- CHECKSUM — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- LSN — read the *pg_control* in the data directory to obtain redo LSN and redo TLI, which allows you to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, data_checksums parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the *pg_control* file must be synched with state of data directory. This condition cannot checked at the start of restore, so it is a user responsibility to ensure that *pg_control* contain valid information. Therefore it is not recommended to use LSN mode in any situation, where pg_control cannot be trusted or has been tampered with: after *pg_resetxlog* execution, after restore from backup without recovery been run, etc.
- NONE — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, pg_probackup will check, that postmaster in given destination directory is not running and `system-identifier` is the same as in the backup.

Suppose you want to return an old primary as a replica after switchover using incremental restore in LSN mode:

```
========================================================================================

```

> **Note**
>
> Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

Partial Restore

If you have enabled partial restore before taking backups, you can restore only some of the databases using partial restore options with the restore commands.

To restore the specified databases only, run the restore command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=db1 --db-
include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=db1 --db-
exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

> **Note**
>
> The `template0` and `template1` databases are always restored.

> **Note**
>
> Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the hot_standby parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

Performing Point-in-Time (PITR) Recovery

If you have enabled continuous WAL archiving before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using recovery target options with the restore command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i`/`--backup-id` option is omitted, pg_probackup automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise pg_probackup will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-time="2024-04-10 18:18:26+03"
  ```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-xid=687
  ```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-lsn=16/B374D848
  ```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-name="before_app_upgrade"
  ```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target="latest"
  ```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target='immediate'
  ```

Using pg_probackup in the Remote Mode

pg_probackup supports the remote mode that allows you to perform `backup` and `restore` operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have pg_probackup installed on both systems.

> **Note**
>
> pg_probackup relies on passwordless SSH connection for communication between the hosts.

> **Note**
>
> In addition to SSH connection, pg_probackup uses a regular connection to the database to manage the remote operation. See the section Configuring the Database Cluster for details of how to set up a database connection.

The typical workflow is as follows:

- On your backup host, configure pg_probackup as explained in the section Installation and Setup. For the add-instance and set-config commands, make sure to specify remote mode options that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in PAGE mode, or rely on ARCHIVE WAL delivery mode, or use PITR, configure continuous WAL archiving from the database host to the backup host as explained in the section Setting up continuous WAL archiving. For the archive-push and archive-get commands, you must specify the remote mode options that point to the backup host with the backup catalog.
- Run backup or restore commands with remote mode options **on the backup host**. pg_probackup connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --remote-
user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --
remote-host=192.168.0.2 --remote-port=2302
```

Restoring an ARCHIVE backup or performing PITR in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use Remote WAL Archive Options.

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port `2302` and user `backup` on backup catalog host with address `192.168.0.3` via port `2303`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres
 --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-
port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --
instance=instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3
 --remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire *restore_command*:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres
 --remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/
```

```
pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p
 --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

> **Note**
>
> The remote mode is currently unavailable for Windows systems.

Running pg_probackup on Parallel Threads

backup, restore, merge, delete, catchup, checkdb, and validate processes can be executed on several parallel threads. This can significantly speed up pg_probackup operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL -j 4
```

> **Note**
>
> Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

> **Important**
>
> A technique is implemented that prevents repeatable copying of one file when pg_probackup runs on multiple threads. With this technique, however, when disks are slow or the system is overloaded, parallel copying might fail. To handle this situation, resolve issues with your system resources.

Configuring pg_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the *backup_dir*`/backups/`*instance_name* directory to fine-tune pg_probackup configuration.

For example, backup and checkdb commands use a regular Postgres Pro connection. To avoid specifying connection options each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the set-config command.

> **Note**
>
> It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define remote mode, retention, logging, and compression settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
 [retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance=instance_name
```

You can override the settings defined in `pg_probackup.conf` when running pg_probackup commands via the corresponding environment variables and/or command line options.

Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent pg_probackup commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default pg_probackup tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

Managing the Backup Catalog

With pg_probackup, you can manage backups from the command line:

- View backup information
- View WAL Archive Information
- Validate backups
- Merge backups
- Delete backups

Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

pg_probackup displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
============================================================================================================
 Instance  Version  ID      Recovery Time                  Mode    WAL Mode  TLI  Time

 144MB  16MB  zstd    2.47  0/22000028  0/220001C8  OK
```

For each backup, the following information is provided:

- `Instance` — the instance name.
- `Version` — Postgres Pro major version.
- `ID` — the backup identifier.
- `Recovery time` — the earliest moment for which you can restore the state of the database cluster.
- `Mode` — the method used to take this backup. Possible values: `FULL`, `PAGE`, `DELTA`, `PTRACK`.
- `WAL Mode` — WAL delivery mode. Possible values: `STREAM` and `ARCHIVE`.
- `TLI` — timeline identifiers of the current backup and its parent.
- `Time` — the time it took to perform the backup.

- `Data` — the size of the data files in this backup. This value does not include the size of WAL files. For STREAM backups, the total size of the backup can be calculated as `Data` + `WAL`.
- `WAL` — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `Zratio` — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- `Start LSN` — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- `Stop LSN` — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- `Status` — backup status. Possible values:
  - `OK` — the backup is complete and valid.
  - `DONE` — the backup is complete, but was not validated.
  - `RUNNING` — the backup is in progress.
  - `MERGING` — the backup is being merged.
  - `MERGED` — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
  - `DELETING` — the backup files are being deleted.
  - `CORRUPT` — some of the backup files are corrupt.
  - `ERROR` — the backup was aborted because of an unexpected error.
  - `ORPHAN` — the backup is invalid because one of its parent backups is corrupt or missing.
  - `HIDDEN_FOR_TEST` — a test script marked the backup as nonexistent. (pg_probackup never sets this status by itself.)

You can restore the cluster from the backup only if the backup status is `OK` or `DONE`.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = lz4
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
xlog-block-size = 8192
checksum-version = 1
program-version = 2.7.3
server-version = 17

#Result backup info
timelineid = 1
start-lsn = 0/41000028
stop-lsn = 0/420000C0
start-time = '2024-04-09 18:19:52+03'
end-time = '2024-04-09 18:19:58+03'
end-validation-time = '2024-04-09 18:19:59+03'
recovery-xid = 757
recovery-time = '2024-04-09 18:19:56.603355+03'
```

```
data-bytes = 395651278
wal-bytes = 16777216
uncompressed-bytes = 578552566
pgdata-bytes = 578552248
status = OK
primary_conninfo = 'user=backup channel_binding=prefer host=localhost
 port=5432 sslmode=prefer sslcompression=0 sslcertmode=allow sslsni=1
 ssl_min_protocol_version=TLSv1.2 gssencmode=prefer krbsrvname=postgres gssdelegation=0
 target_session_attrs=any load_balance_hosts=disable'
content-crc = 3862224379
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on a standby? Possible values: `1`, `0`.
- `block-size` — the block_size setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are data_checksums enabled in the backed up Postgres Pro cluster? Possible values: `1`, `0`.
- `program-version` — full version of pg_probackup binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `end-validation-time` — the backup validation end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression if used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup metainformation.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance=instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
    {
        "instance": "node",
        "backups": [
            {
                "id": "SBOL94",

 target_session_attrs=any load_balance_hosts=disable",
                "content-crc": 3862224379
            }
        ]
    }
]
```

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive
```

pg_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
================================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size   Zratio  N backups  Status
================================================================================================
 1    0           0/0          000000010000000000000001B  000000010000000000000042  40
        640MB  1.00    5          OK
```

For each timeline, the following information is provided:

- `TLI` — timeline identifier.
- `Parent TLI` — identifier of the timeline from which this timeline branched off.
- `Switchpoint` — LSN of the moment when the timeline branched off from its parent timeline.
- `Min Segno` — the first WAL segment belonging to the timeline.
- `Max Segno` — the last WAL segment belonging to the timeline.
- `N segments` — number of WAL segments belonging to the timeline.
- `Size` — the size that files take on disk.
- `Zalg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `Zratio` — compression ratio calculated as `N segments` * *`wal_segment_size`* * *`wal_block_size`* / `Size`.
- `N backups` — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- `Status` — status of the WAL archive for this timeline. Possible values:
  - `OK` — all WAL segments between `Min Segno` and `Max Segno` are present.
  - `DEGRADED` — some WAL segments between `Min Segno` and `Max Segno` are missing. To find out which files are lost, view this report in the JSON format. This status may appear if several WAL files (in the middle of the sequence) were deleted by the delete command with the `--delete-wal`

option according to the retention policy. This status does not affect the restore correctness, but it can be impossible to perform PITR of the cluster to some recovery targets.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive --format=json
```

The sample output is as follows:

```
[
    {
        "instance": "node",
        "timelines": [
            {
                "tli": 1,
                "parent-tli": 0,

            }
        ]
    }
]
```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

Configuring Retention Policy

With pg_probackup, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

Removing Redundant Backups

By default, all backup copies created with pg_probackup are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via set-config:

`--retention-redundancy=`*`redundancy`*

Specifies **the number of full backup copies** to keep in the backup catalog.

`--retention-window=`*`window`*

Defines the earliest point in time for which pg_probackup can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, pg_probackup must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, pg_probackup has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance=instance_name --retention-redundancy=2
 --retention-window=7
```

It is recommended to always keep at least two last parent full backups to avoid errors when creating incremental backups.

To clean up the backup catalog in accordance with retention policy, you have to run the delete command with retention flags, as shown below, or use the backup command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --delete-
wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running backup or delete commands.

Suppose you have backed up the *node* instance in the *backup_dir* directory, with the `--retention-window` option set to `6` and `--retention-redundancy` option set to `2`, and you have the following backups available on August 01, 2024:

```
BACKUP INSTANCE 'node'

 16MB  zstd    2,86  0/B000028   0/C0000C0   OK
 node      17       SGWTN3  2024-07-20 09:49:54+03  PAGE   ARCHIVE   1/1    5s  6432kB
 16MB  zstd    1,06  0/8000028   0/90000C0   OK
 node      17       SGUYZ2  2024-07-19 09:49:53+03  DELTA  ARCHIVE   1/1    5s  6442kB
 16MB  zstd    1,07  0/5000028   0/60000C0   OK
 node      17       SGT4B1  2024-07-18 09:49:52+03  FULL   ARCHIVE   1/0    5s    11MB
 16MB  zstd    2,89  0/2000028   0/3003A28   OK
```

If you run the delete command with the `--delete-expired` flag, the backups with IDs `SGT4B1`, `SGUYZ2`, and `SGWTN3` will be removed as they are expired both according to the retention window and due to redundancy (the required set of full backups has already been retained). `SGUYZ2` and `SGWTN3` will also be removed since the base full backup is expired.

Running the delete command with the `--merge-expired` flag will merge backups `SH48B3` and `SH62Z5` with `SH9SB5`. The merge will occur with `SH9SB5` as it is the first non-expired delta backup, which can be merged with expired delta backups `SH62Z5` and expired full backup `SH48B3`.

```
pg_probackup delete -B backup_dir --instance=node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'

 16MB  zstd    2,84  0/11000028   0/120000C0  OK
```

The `Time` field for the merged backup displays the time required for the merge.

Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --expire-
time="2027-04-09 18:21:32+00"
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the backup command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --expire-
time="2027-04-09 18:21:32+00"
```

To check if the backup is pinned, run the show command:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2024-04-09 18:21:32+00'
expire-time = '2027-04-09 18:21:32+00'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=0
```

> **Note**
>
> A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

Configuring WAL Archive Retention Policy

When continuous WAL archiving is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the set-config command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. Pinned backups are not included into this count: if one of the latest backups is pinned, pg_probackup ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the delete or backup command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the delete and backup commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the *backup_dir* directory and configured continuous WAL archiving:

```
pg_probackup show -B backup_dir --instance=node
```

```

 1364kB  16MB  zstd    1.01  0/6B000028  0/6B000190  OK
 node       17       SBOLCS  2024-04-09 18:22:07.521646+03  DELTA  STREAM    1/1    4s
  78MB   16MB  zstd    2.41  0/69000028  0/69000190  OK
 node       17       SBOLCC  2024-04-09 18:21:55.830115+03  FULL   STREAM    1/0   15s
 278MB   96MB  zstd    2.46  0/600060C8  0/64FE6640  OK
 node       17       SBOLBW  2024-04-09 18:21:38.399702+03  FULL   STREAM    1/0   12s
 278MB   96MB  zstd    2.46  0/54001830  0/589E5908  OK
```

You can check the state of the WAL archive by running the show command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance=node --archive
```

```
ARCHIVE INSTANCE 'node'
========================================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                Max Segno                 N
 segments  Size   Zratio  N backups  Status
========================================================================================================
```

```
 1    0           0/0          000000010000000000000052  000000010000000000000006F  30
        480MB  1.00    6          OK
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
================================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size   Zratio  N backups  Status
================================================================================================
 1    0           0/0          000000010000000000000054  000000010000000000000006F  28
        448MB  1.00    6          OK
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
================================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size  Zratio  N backups  Status
================================================================================================
 1    0           0/0          000000010000000000000006F  000000010000000000000006F  1
        16MB  1.00    6          OK
```

Alternatively, you can use the `--wal-depth` option with the backup command:

```
pg_probackup backup -B backup_dir --instance=node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
================================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size  Zratio  N backups  Status
================================================================================================
 1    0           0/0          000000010000000000000071  000000010000000000000071  1
        16MB  1.00    7          OK
```

Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows you to save much time, especially for large data volumes, as well as I/O and network traffic if you are using pg_probackup in the remote mode.

Before the merge, pg_probackup validates all the affected backups to ensure that they are valid. You can check the current backup status by running the show command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

> **Warning**
>
> Avoid force-terminating the merge operation, as it may cause subsequent `merge` commands to fail and disrupt backup validation.

Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance=instance_name -i backup_id
```

This command will delete the backup with the specified *backup_id*, together with all the incremental backups that descend from *backup_id*, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --merge-expired
```

In this case, pg_probackup searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance=instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

Cloning and Synchronizing Postgres Pro Instance

pg_probackup can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the catchup command. It can be useful in the following cases:

- To add a new standby server.

  Usually, pg_basebackup is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with the primary.

  Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with the primary and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of

extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from the primary.

`catchup` is different from other pg_probackup operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands CREATE TABLESPACE/DROP TABLESPACE cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source server as follows:

- Configure the database cluster for the instance to copy.
- To copy from a remote server, configure the remote mode.
- To use the PTRACK catchup mode, set up PTRACK backups.

Before cloning/synchronizing a Postgres Pro instance, ensure that the source server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the catchup command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where *catchup_mode* can take one of the following values:

- `FULL` — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- `DELTA` — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- `PTRACK` — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

> **Warning**
>
> PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set STREAM WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the server via replication protocol.

You can use connection_options to specify the connection to the source database cluster. If it is located on a different server, also specify remote_options.

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK
 --remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

Command-Line Reference

Commands

This section describes pg_probackup commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section Options.

version

```
pg_probackup version [--format=json]
```

Prints pg_probackup version and edition, as well as Postgres Pro version and edition.

If `--format=json` is specified, the output is printed in the JSON format. This may be needed for native integration with JSON-based applications, such as PPEM. Example of a JSON output:

```
pg_probackup version --format=json
{
    "pg_probackup":
    {
        "version": "2.8.2",
        "edition": "enterprise"
    },
    "database":
    {
        "type": "Postgres Pro Enterprise",
        "version": "16.3.1"
    },
    "compressions": [zlib, pglz, lz4, zstd]
}
```

help

```
pg_probackup help [command]
```

Displays the synopsis of pg_probackup commands. If one of the pg_probackup commands is specified, shows detailed information about the options that can be used with this command.

init

```
pg_probackup init -B backup_dir [--skip-if-exists] [s3_options] [--help]
```

[*logging_options*]

Initializes the backup catalog in *backup_dir* that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified *backup_dir* already exists, it must be empty. Otherwise, pg_probackup displays a corresponding error message. You can ignore this error by specifying the `--skip-if-exists` option. Although the backup will not be initialized, the application will return 0 code.

For details, see the section Initializing the Backup Catalog.

add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
[--skip-if-exists] [s3_options] [--help] [logging_options]
```

Initializes a new backup instance inside the backup catalog *backup_dir* and generates the `pg_probackup.conf` configuration file that controls pg_probackup settings for the cluster with the specified *data_dir* data directory.

`--skip-if-exists`

Allows skipping initialization without raising an error if an instance already exists.

For details, see the section Adding a New Backup Instance.

del-instance

```
pg_probackup del-instance -B backup_dir --instance=instance_name [s3_options] [--help]
[logging_options]
```

Deletes all backups and WAL files associated with the specified instance.

set-config

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy][--retention-window=window][--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options] [s3_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the Options section.

It is **not recommended** to edit `pg_probackup.conf` manually.

set-backup

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [s3_options] [--help] [logging_options]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

`--note=backup_note`

Sets the text note for backup copy. If *backup_note* contains newline characters, then only the substring before the first newline character will be saved. The maximum size of a text note is 1 KB. The *'none'* value removes the current note.

For all available pinning settings, see the section Pinning Options.

show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
 [s3_options]
[--no-scale-units] [logging_options]
```

Displays all the current pg_probackup configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the *backup_dir*`/backups/`*instance_name* directory and those that were provided on a command line. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

You can also specify the `--no-scale-units` option to display time and memory configuration settings in their base (unscaled) units. Otherwise, the values are scaled to larger units for optimal display. For example, if `archive-timeout` is 300, then `5min` is displayed, but if `archive-timeout` is 301, then `301s` is displayed. Also, if the `--no-scale-units` option is specified, configuration settings are displayed without units and for the JSON format, numeric and boolean values are not enclosed in quotes. This facilitates parsing the output.

To edit `pg_probackup.conf`, use the set-config command.

show

```
pg_probackup show -B backup_dir
[--help] [--instance=instance_name [-i backup_id | --archive]] [--format=plain|json]
 [--no-color] [--show-symlinks] [s3_options]
[logging_options]
```

Shows the contents of the backup catalog. If *instance_name* and *backup_id* are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

If the `--show-symlinks` option is specified, the command also shows the links between merged backups and the original full backups that incremental backups were merged to.

For details on usage, see the sections Managing the Backup Catalog and Viewing WAL Archive Information.

backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance=instance_name
[--help] [-j num_threads] [--progress]
[--backup-threads num_threads] [--validate-threads num_threads]
[-C] [--stream [-S slot_name] [--temp-slot[=true|false|on|off]]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password] [--allow-group-access]
[--write-rate-limit=bitrate]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options] [s3_options]
```

Creates a backup copy of the Postgres Pro instance.

`-b` *mode*
`--backup-mode=`*mode*

Specifies the backup mode to use. Possible values are: `FULL`, `DELTA`, `PAGE`, and `PTRACK`.

`--backup-threads` *num_threads*

Specifies the number of threads for copying files. Overrides the `j`/`--threads` option for file copying.

`--validate-threads` *num_threads*

Specifies the number of threads for the backup validation. Overrides the `j`/`--threads` option for the backup validation.

`-C`
`--smooth-checkpoint`

Spreads out the checkpoint over a period of time. By default, pg_probackup tries to complete the checkpoint as soon as possible.

`--stream`

Makes a STREAM backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot[=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the backed up Postgres Pro instance. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot`/`-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-S` *slot_name*
`--slot=`*slot_name*

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E` *external_directory_path*
`--external-dirs=`*external_directory_path*

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--allow-group-access`

Provides read access to backups stored on the backup host to any OS user in the same group as the OS user on the backup host who runs pg_probackup operations.

`--write-rate-limit=`*bitrate*

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the backup:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total backup time.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
 average rate 872.560715 MBps
```

`--archive-timeout=`*wait_time*

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, pg_probackup waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

It is recommended to use this flag when creating a backup to an S3 storage. Due to some features of S3 storages, automatic validation may appear incorrect in this case. Skip automatic validation and then perform validation using a separate validate command.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the validate command once the backup is complete to detect possible issues.

`--note=`*backup_note*

Sets the text note for backup copy. If *backup_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The *'none'* value removes current note.

For more details of the command settings, see sections Common Options, Connection Options, Retention Options, Pinning Options, Remote Mode Options, Compression Options, Logging Options, and S3 Options.

For details on usage, see the section Creating a Backup.

restore

```
pg_probackup restore -B backup_dir --instance=instance_name
[--help] [--dry-run] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync] [--allow-group-access]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options] [s3_options]
```

Restores the Postgres Pro instance from a backup copy located in the *backup_dir* backup catalog. If you specify a recovery target option, pg_probackup finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, pg_probackup uses the most recent backup to perform the recovery.

`-R`
`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the primary_con-

ninfo parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, pg_probackup writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is is started.

`--primary-conninfo=`*`primary_conninfo`*

Sets the primary_conninfo parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`
`--primary-slot-name=`*`slot_name`*

Sets the primary_slot_name parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T` *`OLDDIR=NEWDIR`*
`--tablespace-mapping=`*`OLDDIR=NEWDIR`*

Relocates the tablespace from the *`OLDDIR`* to the *`NEWDIR`* directory at the time of recovery. Both *`OLDDIR`* and *`NEWDIR`* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=`*`OLDDIR=NEWDIR`*

Relocates an external directory included into the backup from the *`OLDDIR`* to the *`NEWDIR`* directory at the time of recovery. Both *`OLDDIR`* and *`NEWDIR`* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--allow-group-access`

Provides any OS user in the same group as the cluster owner with the same access to the `PGDATA` directory on the database server as the cluster owner has. Running `restore` with this option will set the same permissions as when the cluster is created using the command

```
initdb --group access
```

`--restore-command=`*`cmdline`*

Sets the restore_command parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, incremental

restore with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the restore command again.

`-X` *wal_dir*
`--waldir=`*wal_dir*

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. *wal_dir* must be an absolute path, which must not already exist, but if it does, it must be empty.

For more details of the command settings, see sections Common Options, Recovery Target Options, Remote Mode Options, Remote WAL Archive Options, Logging Options, Partial Restore Options, and S3 Options.

For details on usage, see the section Restoring a Cluster.

checkdb

```
pg_probackup checkdb
[-B backup_dir] [--instance=instance_name] [-D data_dir]
[--help] [-j num_threads] [--progress]
[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]
[connection_options] [logging_options]
[s3_options]
```

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

For the command to work correctly, when the backup instance is created in the S3 storage, you must specify S3 options on the command line or through environment variables.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the amcheck extension or the amcheck_next extension installed in the database to check its indexes. For databases without amcheck, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of amcheck installed.

`--checkunique`

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the amcheck extension is installed in the database.

The verification of unique constraints is only possible if in the version of the amcheck extension you are using, the `bt_index_check` function takes the *checkunique* parameter.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the amcheck/amcheck_next extension you are using, the `bt_index_check` function takes the *heapallindexed* parameter.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

For more details of the command settings, see sections Common Options, Connection Options, Logging Options, and S3 Options.

For details on usage, see the section Verifying a Cluster.

validate

```
pg_probackup validate -B backup_dir
[--help] [--instance=instance_name] [-i backup_id]
[-j num_threads] [--progress] [--wal]
[--skip-block-validation]
[recovery_target_options] [logging_options] [s3_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If *instance_name* is not specified, pg_probackup validates all backups available in the backup catalog. If you specify the *instance_name* without any additional options, pg_probackup validates all the backups available for this backup instance. If you specify the *instance_name* with a recovery target option and/or a *backup_id*, pg_probackup checks whether it is possible to restore the cluster using these options. If the `--wal` option is specified, full check of the WAL archive will be performed instead of only checking WAL segments needed to restore the cluster.

For details, see the section Validating a Backup.

> **Note**
>
> The `TATLIN.OBJECT` S3 storage is an “eventually consistent” class system. In such systems, the reconciliation across nodes proceeds asynchronously. Therefore, if you are making a backup to the `TATLIN.OBJECT` S3 storage, perform backup validation not immediately after the backup, but some time later.

merge

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
[--dry-run] [--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For more details of the command settings, see sections Common Options and Merging Backups.

delete

```
pg_probackup delete -B backup_dir --instance=instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy][--retention-window=window][--wal-depth=wal_depth]
 [--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options] [s3_options]
```

Deletes backup with specified *backup_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

--no-validate

Skips automatic validation before and after retention merge.

--no-sync

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections Deleting Backups, Retention Options, and Configuring Retention Policy.

archive-push

```
pg_probackup archive-push -B backup_dir --instance=instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--dry-run] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options] [s3_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance_name* and system-identifier. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: `Refuse to push WAL segment segment_name into archive. Instance parameters mismatch.`

If the files to be copied already exists in the backup catalog, pg_probackup computes and compares their checksums. If the checksums match, archive-push skips the corresponding file and returns a successful execution code. Otherwise, archive-push fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the archive-push command with the --overwrite flag.

Each file is copied to a temporary file with the .part suffix. If the temporary file already exists, pg_probackup will wait archive_timeout seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed archive-push will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

The Postgres Pro server requests WAL segments one at a time. To speed up archiving, you can specify the --batch-size option to copy WAL segments in batches of the specified size. If --batch-size option is used, then you can also specify the -j option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the --no-sync flag is used.

You can use archive-push in the archive_command Postgres Pro parameter to set up continuous WAL archiving.

For more details of the command settings, see sections Common Options, Archiving Options, Compression Options, and S3 Options.

archive-get

```
pg_probackup archive-get -B backup_dir --instance=instance_name --wal-file-
path=wal_file_path --wal-file-name=wal_file_name
[-j num_threads] [--batch-size=batch_size]
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]
[--dry-run] [--help] [remote_options] [logging_options] [s3_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by pg_probackup as part of the restore_command when

restoring backups using a WAL archive. You do not need to set it manually if you use local storage for backups or remote mode.

If you use S3 interface, to ensure that the Postgres Pro server has access to S3 storage to fetch WAL files during restore, you can specify the `--s3-config-file` option that defines the S3 configuration file with appropriate configuration settings, as described in the section called "S3 Options".

The Postgres Pro server requests WAL segments one at a time. To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For more details of the command settings, see sections Common Options, Archiving Options, Compression Options, and S3 Options.

catchup

```
pg_probackup catchup -b catchup_mode
--source-pgdata=path_to_pgdata_on_remote_server
--destination-pgdata=path_to_local_dir
[--help] [-j | --threads=num_threads] [--dry-run]
[--write-rate-limit=bitrate]
[--stream [--temp-slot[=true|false|on|off]] [-P | --perm-slot] [-S | --slot=slot_name]]
[--exclude-path=PATHNAME]
[-T OLDDIR=NEWDIR]
[-X | --waldir=wal_dir]
[connection_options] [remote_options]
[logging_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

`-b catchup_mode`
`--backup-mode=catchup_mode`

Specifies the catchup mode to use. Possible values are: `FULL`, `DELTA`, and `PTRACK`.

`--source-pgdata=path_to_pgdata_on_remote_server`

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

`--destination-pgdata=path_to_local_dir`

Specifies the path to the local data directory to copy to.

`-j num_threads`
`--threads=num_threads`

Sets the number of parallel threads for `catchup` process.

`--stream`

Copies the instance in STREAM WAL delivery mode, including all the necessary WAL files by streaming them from the server via replication protocol. For `catchup`, it is enabled by default.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the `catchup` operation:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total duration of the `catchup` operation.

- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
 average rate 872.560715 MBps
```

`-x=`*`path_prefix`*
`--exclude-path=`*`path_prefix`*

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

> **Warning**
>
> This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot[=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot`/`-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-P`
`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot`/`-S` option.

`-S` *`slot_name`*
`--slot=`*`slot_name`*

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`-T` *`OLDDIR=NEWDIR`*
`--tablespace-mapping=`*`OLDDIR=NEWDIR`*

Relocates the tablespace from the *`OLDDIR`* to the *`NEWDIR`* directory at the time of recovery. Both *`OLDDIR`* and *`NEWDIR`* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`-X` *`wal_dir`*
`--waldir=`*`wal_dir`*

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. *`wal_dir`* must be an absolute path, which must not already exist, but if it does, it must be empty to perform `catchup` with `--catchup-mode=FULL`.

For more details of the command settings, see sections Common Options, Connection Options, and Remote Mode Options.

For details on usage, see the section Cloning and Synchronizing Postgres Pro Instance.

maintain

```
pg_probackup maintain --B backup_dir --instance=instance_name
[-i backup_id] --status-sync [--help] [--dry-run]
[--log-level-console=log-level-console] [--log-level-file=log-level-file]
[--log-format-console=log-format-console] [--log-format-file=log-format-file]
[--log-filename=log-filename]
```

Performs a cleanup of the directory with backups of the specified instance after a forced termination of previous pg_probackup commands.

`--status-sync`

Detects expired locks and hanging backups, as well as updates backup statuses.

For more details of the command settings, see sections Common Options and Logging Options.

Options

This section describes command-line options for pg_probackup commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see the section called “Configuring pg_probackup”.

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

Common Options

The list of general options.

`--dry-run`

Initiates a trial run of the appropriate command, which does not actually do any changes, that is, it does not create, delete or move files on disk. This flag allows you to check that all the command options are correct and the command is ready to run. WAL streaming is skipped with `--dry-run`.

`-B` *directory*
`--backup-path=`*directory*
`BACKUP_PATH`

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the pg_probackup commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

`-D` *directory*
`--pgdata=`*directory*
`PGDATA`

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the add-instance command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

`-i` *backup_id*
`--backup-id=`*backup_id*

Specifies the unique identifier of the backup.

`--instance` *instance_name*

Specifies the name of the Postgres Pro instance.

`-j` *num_threads*
`--threads=`*num_threads*

Sets the number of parallel threads for `backup`, `restore`, `merge`, `validate`, `checkdb`, and `archive-push` processes.

`--progress`

Shows the progress of operations.

`--help`

Shows detailed information about the options that can be used with this command.

Recovery Target Options

If continuous WAL archiving is configured, you can use one of these options together with restore or validate commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i`/`--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. Setting this value of `--recovery-target` also sets `--recovery-target-timeline` to `latest`.

`--recovery-target-timeline=`*timeline*

Specifies a particular timeline to be used for recovery:

- `current` — the timeline of the specified backup, default.
- `latest` — the timeline of the latest available backup.
- A numeric value.

`--recovery-target-lsn=`*lsn*

Specifies the LSN of the write-ahead log location up to which recovery will proceed.

`--recovery-target-name=`*recovery_target_name*

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=`*time*

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2027-04-09 18:21:32+00"`

`--recovery-target-xid=`*xid*

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=`*boolean*

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the recovery_target_inclusive parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies recovery_target_action the server should take when the recovery target is reached.

Default: `pause`

Retention Options

You can use these options together with backup and delete commands.

For details on configuring retention policy, see the section Configuring Retention Policy.

`--retention-redundancy=`*`redundancy`*

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--retention-window=`*`window`*

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--wal-depth=`*`wal_depth`*

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

Pinning Options

You can use these options together with backup and set-backup commands.

For details on backup pinning, see the section Backup Pinning.

`--ttl=`*`ttl`*

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=`*`time`*

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2027-04-09 18:21:32+00"`

Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of `warning` and `error` levels.

`--log-level-console=`*`log_level`*

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

> **Note**
>
> All console log messages are going to stderr, so the output of show and show-config commands does not mingle with log messages.

`--log-level-file=`*`log_level`*

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=`*`log_filename`*

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, pg_probackup generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=`*`error_log_filename`*

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: none

For example, if you specify the `error-pg_probackup-%u.log` pattern, pg_probackup generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=`*`log_directory`*

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Note that the directory for log files is always created locally even if backups are created in the S3 storage. So be sure to pass a local path in *`log_directory`* when needed.

Default: `$BACKUP_PATH/log/`

`--log-format-console=`*`log_format`*

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the set-config command and that the backup command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.
- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=`*`log_format`*

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: `plain`

`--log-rotation-size=`*`log_rotation_size`*

Maximum size of an individual log file. If this value is reached, the log file is rotated once a pg_probackup command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: `0`

`--log-rotation-age=`*`log_rotation_age`*

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a pg_probackup command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: `0`

Connection Options

You can use these options together with backup, catchup, and checkdb commands.

All libpq environment variables are supported.

`-d` *`dbname`*
`--pgdatabase=`*`dbname`*
`PGDATABASE`

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, pg_probackup tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

`-h` *`host`*
`--pghost=`*`host`*
`PGHOST`

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: `localhost`

`-p` *port*
`--pgport=`*port*
`PGPORT`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: `5432`

`-U` *username*
`--pguser=`*username*
`PGUSER`

User name to connect as.

`-w`
`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file or `PGPASSWORD` environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Forces a password prompt. (Deprecated)

Compression Options

You can use these options together with backup and archive-push commands.

`--compress-algorithm=`*compression_algorithm*

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `lz4`, `zstd`, `pglz`, and `none`. If set to any value, but `none`, this option enables compression that uses the corresponding algorithm. Both data files and WAL files are compressed. By default, compression is disabled. For the archive-push command, the `pglz` compression algorithm is not supported.

> **Note**
>
> pg_probackup supports compression algorithms included in the Postgres Pro version. In particular:
>
> - lz4 is supported for Postgres Pro Enterprise 13 and higher.
> - zstd is supported for Postgres Pro Enterprise 11 and higher.

Default: `none`

`--compress-level=`*compression_level*

Defines the compression level. This option can be used together with the `--compress-algorithm` option. Possible values depend on the compression algorithm specified:

- 0 — 9 for `zlib`
- 1 for `pglz`
- 0 — 12 for `lz4`
- 0 — 22 for `zstd`

The value of 0 sets the default compression level for the specified algorithm:

- 6 for `zlib`

- 1 for `pglz`
- 9 for `lz4`
- 3 for `zstd`

> **Note**
>
> The pure lz4 algorithmn has only one compression level — 1. So, if the specified compression algorithm is `lz4` and `--compress-level` is greater than 1, the lz4hc algorithm is actually used, which is much slower although does better compression.

Default: `1`

`--compress`

Specifies the default compression algorithm and `--compress-level=1`. The default algorithm is selected among those supported by Postgres Pro according to the priorities: `zstd` (highest) -> `lz4` -> `zlib` -> `pglz`. The `--compress` option overrides the `--compression-algorithm` and `--compress-level` settings and cannot be specified together with them.

Archiving Options

These options can be used with the archive-push command in the archive_command setting and the archive-get command in the restore_command setting.

Additionally, remote mode options and logging options can be used.

`--wal-file-path=`*`wal_file_path`*

Provides the path to the WAL file in *`archive_command`* and *`restore_command`*. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=`*`wal_file_name`*

Provides the name of the WAL file in *`archive_command`* and *`restore_command`*. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the archive-push command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=`*`batch_size`*

Used to speed up archiving in case of `archive-push` or to speed up recovery in case of `archive-get`. Sets the maximum number of WAL files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=`*`wait_time`*

Sets the timeout for considering existing `.part` files to be stale. By default, pg_probackup waits 300 seconds. This option can be used only with archive-push command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if *`archive_command`* contains multiple commands. This option can be used only with archive-push command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with archive-push command.

`--prefetch-dir=`*`path`*

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with archive-get command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with archive-get command.

Remote Mode Options

This section describes the options related to running pg_probackup operations remotely via SSH. These options can be used with add-instance, set-config, backup, catchup, restore, archive-push, and archive-get commands.

For details on configuring and using the remote mode, see the section called “Configuring the Remote Mode” and the section called “Using pg_probackup in the Remote Mode”.

`--remote-proto=`*`proto`*

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=`*`destination`*

Specifies the remote host IP address or hostname to connect to.

`--remote-port=`*`port`*

Specifies the remote host port to connect to.

Default: `22`

`--remote-user=`*`username`*

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=`*`path`*

Specifies pg_probackup installation directory on the remote system.

`--ssh-options=`*`ssh_options`*

Provides a string of SSH command-line options. For example, the following options can be used to set *`keep-alive`* for SSH connections opened by pg_probackup: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see *ssh_config manual page*.

Remote WAL Archive Options

This section describes the options used to provide the arguments for remote mode options in archive-get used in the restore_command command when restoring ARCHIVE backups or performing PITR.

`--archive-host=`*`destination`*

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=`*`port`*

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: `22`

`--archive-user=`*`username`*

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the restore command.

`-I` *`incremental_mode`*
`--incremental-mode=`*`incremental_mode`*

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the restore command.

`--db-exclude=`*`dbname`*

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=`*`dbname`*

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

S3 Options

This section describes the options needed to store backups in private clouds. These options can be used with any commands that pg_probackup runs using S3 interface.

`--s3=`*`s3_interface_provider`*

Specifies the S3 interface provider. Possible values are:

- `minio` — MinIO object storage, compatible with S3 cloud storage service. With this provider, custom S3 server settings can be specified. The HTTP protocol, port 9000, and region `us-east-1` are used by default.
- `vk` — VK Cloud storage. With this provider, the S3 host address `hb.vkcs.cloud`, port 443, and HTTPS protocol are only used. Custom values of the host, port, and protocol are ignored. The default value of region is `ru-msk`.
- `aws` — Amazon S3 storage, offered by Amazon Web Services (AWS). With this provider, the S3 host address *`bucket_name`*`.s3.`*`region`*`.amazonaws.com`, port 443, and HTTPS protocol are only

used. Custom values of the host, port, and protocol are ignored. The default value of region is `us-east-1`.

With `--s3=minio`, pg_probackup will work fine for a VK Cloud storage if the S3 host address, port and protocol are properly specified (host address is `hb.vkcs.cloud` or the one specified in the appropriate section of the VK Cloud profile, port 443, and HTTPS protocol). Do not specify `--s3=minio` for the Amazon S3 storage.

Once a pg_probackup command runs with the `--s3` option, pg_probackup starts running all commands that support parallel execution on 10 parallel threads (for details, see the section called “Running pg_probackup on Parallel Threads”). You can change the number of threads using the `-j`/`--threads` option.

`--s3-config-file=`*`path_to_config_file`*

Specifies the S3 configuration file. Settings in the configuration file override the environment variables. If this option is not specified, pg_probackup first looks for the S3 configuration file at `/etc/pg_probackup/s3.config` and then at `~postgres/.pg_probackup/s3.config`. The following is an example of the S3 configuration file:

```
access-key = ...
secret-key = ...
s3-host = localhost
s3-port = 9000
s3-bucket = s3demo
s3-region=us-east-1
s3-buffer-size = 32
s3-secure = on | https | http | off
```

Testing and Debugging Options

This section describes options useful only in a test or development environment.

`--cfs-nondatafile-mode`

Instructs backup command to backup CFS in a legacy mode. This allows fine-tuning compatibility with pg_probackup versions earlier than 2.6.0. This option is mainly designed for testing.

`PGPROBACKUP_TESTS_SKIP_HIDDEN`

Instructs pg_probackup to ignore backups marked as hidden. Note that pg_probackup can never mark a backup as hidden. It can only be done by directly editing the `backup.control` file. This option can only be set with environment variables.

`--destroy-all-other-dbs`

By default, pg_probackup exits with an error if an attempt is made to perform a partial incremental restore since this destroys databases not included in the restore set. This flag allows you to suppress the error and proceed with the partial incremental restore (e.g., to keep a development database snapshot up-to-date with a production one). This option can be used with the restore command.

> **Important**
>
> Never use this flag in a production cluster.

`--lock-lifetime`

Specifies the lifetime for locks taken when performing a backup, in seconds. The default value is 300. The minimum value is 60.

`PGPROBACKUP_TESTS_SKIP_EMPTY_COMMIT`

Instructs pg_probackup to skip empty commits after pg_backup_stop.

Versioning

pg_probackup follows *semantic* versioning.

Authors

Postgres Professional, Moscow, Russia.

Credits

pg_probackup utility is based on pg_arman, which was originally written by NTT and then developed and maintained by Michael Paquier.

vacuumlo

vacuumlo — remove orphaned large objects from a Postgres Pro database

Synopsis

`vacuumlo` [*option*...] *dbname*...

Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the lo module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

vacuumlo accepts the following command-line arguments:

`-l` *limit*
`--limit=`*limit*

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding max_locks_per_transaction. Set the limit to zero if you want all removals done in a single transaction.

`-n`
`--dry-run`

Don't remove anything, just show what would be done.

`-v`
`--verbose`

Write a lot of progress messages.

`-V`
`--version`

Print the vacuumlo version and exit.

`-?`
`--help`

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

`-h` *host*
`--host=`*host*

Database server's host.

`-p` *port*
`--port=`*port*

Database server's port.

`-U` *username*
`--username=`*username*

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Environment

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 37.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Author

Peter Mount `<peter@retep.org.uk>`

I.2. Third-Party Client Applications

This section covers third-party client applications included in the Postgres Pro Enterprise distribution. They can be run from anywhere, independent of where the database server resides. Note also that the odbc driver is available (see Table 17.3 for details).

pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

Synopsis

`pgbadger` [*`connection-option`*...] [*`option`*...] [*`logfile`*...]

Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

`logfile` can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass "-" as *`logfile`*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the log_line_prefix configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

pgbouncer log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at *https://pgbadger.darold.net/#reports*.

Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

Setup and Configuring

pgbadger is provided with Postgres Pro Enterprise as a separate pre-built package `pgbadger` (for the detailed installation instructions, see Chapter 17). Once you have pgbadger installed, complete the setup described in sections below.

[Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

[Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

  ```
  sudo yum install perl-JSON-XS
  ```

[Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- zcat for `gz`
- bzcat for `bz2`
- lz4cat for `lz4`
- zstdcat for `zst`
- unzip or xz for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"
--zcat="C:\tools\unzip -p"
```

> **Note**
>
> With the default autodetection of the compressed file format, you can mix gz, bz2, lz4, xz, zip and zstd log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

  To enable SQL query logging and have the query statistics include actual query strings, set

  ```
  log_min_duration_statement = 0
  ```

  On a busy server you may want to increase this value to only log queries with a longer duration.

  If you just want to report the duration and number of queries and do not want details of queries, set log_min_duration_statement to -1, which disables logging statement durations, and enable log_duration.

  Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set log_statement to `all`, the setting of `log_min_duration_statement` will have no effect.

  > **Warning**
  >
  > Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in log_line_prefix.

  It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for stderr logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable log_statement as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-16/data/log/postgres.log.2.gz /var/lib/pgpro/ent-16/data/
log/postgres.log.1.gz /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-16/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/ent-16/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/ent-16/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/ent-16/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@%d %p %r %a : ' /var/lib/pgpro/ent-16/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/ent-16/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/ent-16/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/ent-16/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/ent-16/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/ent-16/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote pgbouncer log file together:

```
pgbadger /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in pgbadger follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks pgbadger may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

```
 Option |  1 CPU  | 2 CPU | 4 CPU | 8 CPU
--------+---------+-------+-------+------
   -j   | 1h41m18 | 50m25 | 25m39 | 15m58
   -J   | 1h41m18 | 54m28 | 41m16 | 34m45
```

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

```
 Option | 1 CPU | 2 CPU | 4 CPU | 8 CPU
--------+-------+-------+-------+------
```

```
-j   | 20m15 |  9m56 |  5m20 | 4m20
-J   | 20m15 |  9m49 |  5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

> **Important**
>
> During parallel parsing, pgbadger generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/ent-16/data/log/ -mtime -7 -name
 "postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +\%F`.html -l /var/reports/
pgbadger_incremental_file.dat
```

But better turn on pgbadger's automatic building incremental reports by specifyng the `-I`/`--incremental` option. In this mode, pgbadger builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O`/`--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run pgbadger as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/ent-16/data/log/postgresql/
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode pgbadger will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run pgbadger in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-X`/`--extra-files` command-line option to force pgbadger to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O`/`--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/ent-16/data/log/postgresql/
postgresql.log.1 -O /var/www/pg_reports/
```

If pg_dump is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by pg_dump on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

Rebuilding Reports

To update all HTML reports after fixing a pgbadger report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js
rm /path/to/reports/*.css
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E`/`--explode` option if the reports were built with this option.

Building Monthly Reports

By default, in the incremental mode pgbadger only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E`/`--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

Choosing the Report File Format

The pgbadger report file format is determined by the extension of the file passed to the `-o`/`--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a pgbadger report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
ent-16/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of pgbadger output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
  pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
ent-16/data/log/postgresql-2022-01-14_000000.log
```

Return Codes

pgbadger return codes depend on how it terminated as follows:

- `0`: was a success
- `1`: died on error
- `2`: has been interrupted using `Ctrl+C`, for example
- `3`: the PID file already exists or cannot be created

- `4`: no log file was specified on the command line

Options

This section describes pgbadger command-line options.

`-a` *minutes*
`--average` *minutes*

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A` *minutes*
`--histo-average` *minutes*

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b` *datetime*
`--begin` *datetime*

Timestamp or time that specifies the start date/time for the data to be parsed in logs.

`-c` *host*
`--dbclient` *host*

Only report on log entries for the specified client host.

`-C`
`--nocomment`

Remove /* ... */ comments from queries.

`-d` *name*
`--dbname` *name*

Only report on log entries for the specified database.

`-D`
`--dns-resolv`

Replace client IP addresses with their DNS names.

> **Warning**
>
> This can considerably slow down pgbadger.

`-e` *datetime*
`--end` *datetime*

Timestamp or time that specifies the end date/time for the data to be parsed in logs.

`-E`
`--explode`

Build one report per each database. Global information not related to any database gets added to the `postgres` database report.

`-f` *logtype*
`--format` *logtype*

Specifies the log type.

Possible values: `syslog`, `syslog2`, `stderr`, `jsonlog`, `csv`, `pgbouncer`, `logplex`, `rds` and `redshift`. Use when pgbadger cannot detect the log format.

`-G`
`--nograph`

Disables graphs in HTML output.

`-h`
`--help`

Show detailed information about pbadger options and exit.

`-H` *path*
`--html-outdir` *path*

Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by `-O`/`--outdir`.

`-i` *name*
`--ident` *name*

Specifies the program name used to identify Postgres Pro messages in syslog logs.

Default: `postgres`.

`-I`
`--incremental`

Use the incremental mode, where reports will be generated by days in a separate directory specified by the `-O`/`--outdir` option.

`-j` *number*
`--jobs` *number*

Specifies the number of jobs to run at the same time. When working with csvlog logs, pgbadger always runs as single job.

Default: 1.

`-J` *number*
`--Jobs` *number*

Specifies the number of log files to parse in parallel.

Default: 1.

`-l` *filename*
`--last-parsed` *filename*

Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.

`-L` *filename*
`--logfile-list` *filename*

Specifies the file containing the list of log files to parse.

`-m` *size*
`--maxlength` *size*

Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

`-M`
`--no-multiline`

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

`-N` *name*
`--appname` *name*

Only report on log entries for the specified application.

`-o` *filename*
`--outfile` *filename*

Specifies the filename for the output and determines the report file format: `out.html`, `out.txt`, `out.bin` or `out.json`. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of "-" as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,

for the respective output format.

`-O` *path*
`--outdir` *path*

Specifies the directory where out files must be saved.

`-p` *string*
`--prefix` *string*

Specifies the value of your custom log_line_prefix string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from the standard `log_line_prefix` strings, for example, if your prefix includes additional variables, such as client IP or application name. The string must contain escape sequences for time (%t, %m or %n) and processes (%p or %c).

`-P`
`--no-prettify`

Disables SQL query code prettifier.

`-q`
`--quiet`

Disables printing anything to stdout, even the progress bar.

`-Q`
`--query-numbering`

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

`-r` *address*
`--remote-host` *address*

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

`-R` *number*
`--retention` *number*

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s` *number*
`--sample` *number*

Specifies the number of query samples to store.

Default: 3.

`-S`
`--select-only`

Only report on SELECT queries.

`-t` *number*
`--top` *number*

Specifies the number of queries to store/display.

Default: 20.

`-T` *string*
`--title` *string*

Specifies the title of the HTML report page.

`-u` *username*
`--dbuser` *username*

Only report on log entries for the specified username.

`-U` *username*
`--exclude-user` *username*

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`
`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`
`--version`

Show pgbadger version and exit.

`-w`
`--watch-mode`

Only report errors, just like *Logwatch* can do.

`-W`
`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages “Wide character in print”.

`-x` *format*
`--extension` *format*

Specfies the output format. Possible values: `text`, `html`, `bin` or `json`.

Default: `html`.

`-X`
`--extra-files`

In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

`-z` *command*
`--zcat` *command*

Specifies the full command to run the zcat program. Use if zcat, bzcat or unzip is outside of your `PATH` directories.

`-Z` *+/-XX*
`--timezone` *+/-XX*

Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--pie-limit` *number*

Specifies the number such that instead of lower pie data the sum will be shown.

`--exclude-query` *regexp*

Specifies the regular expression such that matching queries will be excluded from the report. For example: "^(VACUUM|COMMIT)". Can be used multiple times.

`--exclude-file` *filename*

Specifies the path to the file that contains each regular expression to use to exclude matching queries from the report, one expression per line.

`--include-query` *regexp*

Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: "(tbl1|tbl2)".

`--include-file` *filename*

Specifies the path to the file that contains each regular expression to use to include matching queries in the report, one expression per line.

`--disable-error`

Turns off generation of an error report.

`--disable-hourly`

Turns off generation of an hourly report.

`--disable-type`

Turns off generation of a report on queries by type, database and user.

`--disable-query`

Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

`--disable-session`

Turns off generation of a session report.

`--disable-connection`

Turns off generation of a connection report.

`--disable-lock`

Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset` *name*

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator` *char*

Specifies the CSV field separator.

Default: “,”.

`--exclude-time` *regexp*

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--include-time` *regexp*

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--exclude-db` *name*

Specifies the name of the database to exclude related log entries from the report. For example: “outdated_db”. Can be used multiple times.

`--exclude-appname` *name*

Specifies the name of the application to exclude related log entries from the report. For example: “pg_dump”. Can be used multiple time.

`--exclude-line` *regexp*

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client` *name*

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl` *command*

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-ent-16`.

`--pid-dir` *path*

Specifies the path to store the PID file.

Default: `/tmp`.

`--pid-file` *filename*

Specifies the name of the PID file to manage concurrent execution of pgbadger.

Default: `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show pgbouncer-related menus in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday (by default, they start on Sunday) with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone` *+/-XX*

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--prettify-json`

Prettify JSON output.

`--month-report` *YYYY-MM*

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report` *YYYY-MM-DD*

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by auto_explain.

`--command` *cmd*

Specifies the command to run to retrieve log entries on stdin. pgbadger will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url` *URL*

Specifes the URL to override the URL of the graphical explain tool.

Default: *http://explain.depesz.com/*

`--tempdir` *path*

Specifies the directory for temporary files.

Default: `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

`--dump-raw-csv`

Parse the log and dump the information into CSV format. No further processing is done, no report.

`--include-pid` *PID*

Only report events related to the session PID (%p). Can be used multiple times.

`--include-session` *ID*

Only report events related to the session ID (%c). Can be used multiple times.

`--histogram-query` *VAL*

Use custom inbound for query time histogram. Default inbound in milliseconds: 0,1,5,10,25,50,100,500,1000,10000.

`--histogram-session` *VAL*

Use custom inbound for session time histogram. Default inbound in milliseconds: 0,500,1000,30000,60000,600000,1800000,3600000,28800000.

Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r`/`--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program` *ssh*

Specifies the path to the SSH program to use.

Default: ssh.

`--ssh-port` *port*

Specifies the SSH port for the connection.

Default: 22.

`--ssh-user` *username*

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity` *filename*

Specifies the path to the identity file.

`--ssh-timeout` *seconds*

Specifies the timeout in seconds in case of the SSH connection failure.

Default: 10.

`--ssh-option` *options*

Specifies the list of options to define SSH connection parameters. The following options are always used:

```
-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey
```

```
-o PreferredAuthentications=hostbased,publickey
```

pg_repack

pg_repack — utility and Postgres Pro Enterprise extension to reorganize tables

Synopsis

`pg_repack` [*option*...] [*dbname*]

Description

pg_repack is a Postgres Pro Enterprise extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike CLUSTER and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. pg_repack is efficient to boot, with performance comparable to using `CLUSTER` directly.

pg_repack is a fork of the previous *https://github.com/reorg/pg_reorg* project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

> **Note**
>
> Only superusers can use the utility.

> **Note**
>
> Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

Installation

On Linux systems, pg_repack is provided together with Postgres Pro Enterprise as a separate pre-built package `pg-repack-ent-16` and requires the `postgrespro-ent-16-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see Chapter 17. On Windows systems, pg_repack is automatically installed as part of Postgres Pro.

Once you have pg_repack installed, load the `pg_repack` extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove `pg_repack` from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of pg_repack, just drop the old version from the database as explained above and install the new version.

Options

Reorganization Options

`-a`
`--all`

Attempt to repack all the databases of the cluster. Databases where the `pg_repack` extension is not installed will be skipped.

`-t` *table*
`--table=`*table*

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-I` *table*
`--parent-table=`*table*

Reorganize both the specified table(s) and its inheritors. Multiple table hierarchies may be reorganized by writing multiple `-I` switches.

`-c` *schema*
`--schema=`*schema*

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o` *column*`[, ...]`
`--order-by=`*column*`[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`
`--dry-run`

Show what would be repacked and exit.

`-j` *num_jobs*
`--jobs=`*num_jobs*

Create the specified number of extra connections to Postgres Pro, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up pg_repack.

`-s` *tablespace*
`--tablespace=`*tablespace*

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i` *index*
`--index=`*index*

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T` *secs*
`--wait-timeout=`*secs*

pg_repack needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds pg_repack will wait to acquire this lock. If the lock cannot be taken after this duration and `--no-kill-backend` option is not specified, pg_repack will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, pg_repack will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-D`
`--no-kill-backend`

Skip repacking a table if the lock cannot be taken for duration specified in `--wait-timeout`, instead of cancelling conflicting queries. The default is `false`.

`-Z`
`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

`-k`
`--no-superuser-check`

Skip the superuser checks in the client. This setting is useful for using pg_repack on platforms that support running it as non-superusers.

`-C`
`--exclude-extension`

Skip tables that belong to the specified extension(s). Some extensions may heavily depend on such tables at planning time etc.

`--switch-threshold`

Switch tables when that many tuples are left in the log table. This setting can be used to avoid the inability to catch up with write-heavy tables.

Connection Options

Options to connect to servers. You cannot use `--all` and `--dbname` or `--table` or `--parent-table` together.

`-a`
`--all`

Reorganize all databases.

`[-d]` *dbname*
`[--dbname=]`*dbname*

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h` *host*
`--host=`*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p` *port*
`--port=`*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U` *username*
`--username=`*username*

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force pg_repack to prompt for a password before connecting to a database.

This option is never essential, since pg_repack will automatically prompt for a password if the server demands password authentication. However, pg_repack will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Generic Options

`-e`
`--echo`

Echo the commands that pg_repack generates and sends to the server.

`-E` *level*
`--elevel=`*level*

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

`--help`

Show help about pg_repack command line arguments, and exit.

`-V`
`--version`

Print the pg_repack version and exit.

Environment

`PGDATABASE`
`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 37.15).

Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

Diagnostics

Error messages are reported when pg_repack fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
pg_repack VER is not installed in the database:
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
There is a mismatch between the pg_repack binary and the database library
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
The SQL extension found in the database does not match the version required by the
 pg_repack program.
```

You should drop the extension from the database and reload it as described in the section called “Installation”.

```
ERROR: relation "table" must have a primary key or not-null unique keys:
```

```
The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.
```

Define a PRIMARY KEY or a UNIQUE constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see the section called “Installation” for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last BEFORE trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
 ON sometable RENAME TO yyy_my_trigger;
```

```
ERROR: Another pg_repack command may be running on the table. Please try again later.
```

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

```
WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous
pg_repack on the table which was interrupted. Please use DROP INDEX
"schema"."index_xxxxx" to remove this index and try again.
```

A temporary index apparently created by pg_repack has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old pg_repack job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

Restrictions

pg_repack comes with the following restrictions.

Temporary tables

pg_repack cannot reorganize temporary tables.

GiST indexes

pg_repack cannot cluster tables by `GiST` indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while pg_repack is working. pg_repack will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while pg_repack is running. In many cases pg_repack would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

See also

clusterdb, vacuumdb

I.3. Additional Postgres Pro Server Applications

This section covers additional Postgres Pro Enterprise server-related applications. They are typically run on the host where the database server resides. See also Postgres Pro Server Applications for information about server applications that are part of the core Postgres Pro Enterprise distribution.

mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics

Synopsis

`mamonsu agent` [*agent_action*]

`mamonsu bootstrap -M` *mamonsu_user* [`-c` | `--config`] [`-x` | `--create-extensions`] [*connection_options*]

`mamonsu export` {`template` | `config`} *filename* [*export_options*]

`mamonsu report` [*report_options*] [*connection_options*]

`mamonsu tune` [*tuning_options*] [*connection_options*]

`mamonsu upload` [*upload_options*]

`mamonsu zabbix dashboard upload` *template_name*

`mamonsu zabbix` {`template` | `host` | `hostgroup`} *server_action*

`mamonsu zabbix item` {`error` | `lastvalue` | `lastclock`} *host_id*

`mamonsu zabbix version`

`mamonsu` [`-c` | `--config`] [`-d` | `--daemonize`]

`mamonsu --version`

`mamonsu --help`

Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in the section called “Command-Line Reference”.

Installation and Setup

> **Important**
>
> Before you start installation, attentively read Compatibility Considerations.

To use mamonsu, you must create a Zabbix account and set up a Zabbix server as explained in *Zabbix documentation*. Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see Chapter 17 and Section 18.2 for Postgres Pro installation and setup instructions, respectively.

> **Note**
>
> While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

mamonsu is provided with Postgres Pro Enterprise as a separate pre-built package `mamonsu` (for the detailed installation instructions, see Chapter 17). Once you have installed mamonsu, complete the following steps to set up metrics collection:

1. **Optionally, bootstrap mamonsu**

   If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

   In this step, the `bootstrap` command sets the mamonsu user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

   `bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of bootstrap:

   1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see Connection Parameters.
   2. Run the following command to bootstrap mamonsu:

      ```
      mamonsu bootstrap
      ```

      This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

   In the following example, `bootstrap` options are passed explicitly.

   1. Create a non-privileged database user for mamonsu. For example:

      ```
      CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
      GRANT pg_monitor TO mamonsu_user;
      ```

   2. Create a database that will be used for connection to Postgres Pro. For example:

      ```
      CREATE DATABASE mamonsu_database OWNER mamonsu_user;
      ```

   3. Run the following command to bootstrap mamonsu:

      ```
      mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/agent.conf -d
       mamonsu_database -U postgres --host myhost --port 5432
      ```

      For details of the options `-M`, `-x` and `-c`, see `bootstrap`. For details of other options, see Connection Options. This command will create monitoring functions in the *`mamonsu_database`* and grant the right to execute them to *`mamonsu_user`*. The pg_buffercache extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

   As a result, a superuser connection is no longer required. Note that mamonsu also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for mamonsu to work.

2. **Configure mamonsu**

   Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

   - Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

     ```
     [zabbix]
     ; enabled by default
     enabled = True
     client = zabbix_host_name
     address = zabbix_server
     ```

   - By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

     ```
     [system]
     ; enabled by default
     enabled = True
     ```

     > **Note**
     >
     > While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

   - If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the *`mamonsu_user`*, *`mamonsu_password`*, and the *`mamonsu_database`* used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

     ```
     [postgres]
     ; enabled by default
     enabled = True
     user = mamonsu_user
     database = mamonsu_database
     password = mamonsu_password
     port = 5432
     ```

   These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in the section called “Configuration Parameters”.

3. **Configure how to display metrics on the Zabbix server**

   1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

      ```
      mamonsu export template template.xml
      ```

      mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-`*`OS`*, where *`OS`* is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

   2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

> **Tip**
>
> If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See the section called “Managing Zabbix Server Settings from the Command Line” for details.

When the setup is complete, start mamonsu. For example, on Linux systems, you can start mamonsu as a service with the following command:

```
service mamonsu start
```

mamonsu picks up all the parameters from the mamonsu configuration file and starts monitoring your system.

Command-Line Reference

agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that mamonsu is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get` *`metric_name`*

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display mamonsu version.

bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
        [-c[ config_file] | --config[=config_file]]
        [-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

`-M`

Specify a non-privileged user that will own all mamonsu processes.

`-c config_file`
`--config=config_file`

Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through *connection_options*.

Default: `/etc/mamonsu/agent.conf`

`-x`
`--create-extensions`

Create auxiliary extensions. The pg_buffercache extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the pgpro_stats extension and grant the right to execute them to the `mamonsu` user.

connection_options

Provide optional *command-line connection parameters*.

export

Syntax:

```
mamonsu export config filename.conf  [--add-plugins=plugin_directory]
mamonsu export template filename.xml [--add-plugins=plugin_directory]
                                     [--template-name=template_name]
                                     [--application=application_name]
                                     [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
                                       [--plugin-type={pg | sys | all}]
                                       [--pg-version=version]
                                       [--config=config_file]
```

Export metrics configuration for use with the native *Zabbix agent*. The optional parameters to customize metrics collection are as follows:

`--add-plugins=`*`plugin_directory`*

Collect metrics that are defined in custom plugins located in the specified *`plugin_directory`*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=`*`version`*

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=`*`config_file`*

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
                                       [--plugin-type={pg | sys | all}]
                                       [--template-name=template_name]
                                       [--application=application_name]
                                       [--config=config_file]
                                       [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=`*`plugin_directory`*

Collect metrics that are defined in custom plugins located in the specified *`plugin_directory`*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=`*`template_name`*

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-`*`OS`*, where *`OS`* is the name of your operating system

`--application=`*`application_name`*

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-`*`OS`*, where *`OS`* is the name of your operating system

`--config=`*`config_file`*

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=`*`Boolean`*

Include system information into the generated report.

Default: `True`

`--run-postgres=`*`Boolean`*

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=`*`Boolean`*

Print the report to stdout.

Default: `True`

`--report-path=`*`report_file`*

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

connection_options

Provide optional *command-line connection parameters*.

tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
             [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune pgbadger parameters.

`--log-level { INFO | DEBUG | WARN}`

Change the logging level.

Default: `INFO`

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

connection_options

Provide optional *command-line connection parameters*.

upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see the section called “Logging Parameters”.

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: `localhost`

`--zabbix-port=`*`port_number`*

The port of the Zabbix server.

Default: 10051

`--zabbix-file=`*`metrics_file`*

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=`*`zabbix_host_name`*

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

zabbix dashboard upload

Syntax:

```
mamonsu dashboard upload template_name
```

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

zabbix item

Syntax:

```
mamonsu zabbix item {error | lastvalue | lastclock } host_name
```

View the specified property of the latest metrics data received by Zabbix for the specified host.

zabbix version

Syntax:

```
mamonsu zabbix version
```

Get the version of the Zabbix server that mamonsu is connected to.

zabbix host

Syntax:

```
mamonsu zabbix host list
mamonsu zabbix host show host_name
mamonsu zabbix host id host_name
mamonsu zabbix host delete host_id
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id
```

Manage Zabbix hosts using one of the actions described in the section called “Zabbix Server Actions”.

zabbix hostgroup

Syntax:

```
mamonsu zabbix hostgroup list
mamonsu zabbix hostgroup show hostgroup_name
mamonsu zabbix hostgroup id hostgroup_name
```

```
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in the section called "Zabbix Server Actions".

zabbix template

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in the section called "Zabbix Server Actions".

[--config] [--daemonize]

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

`-c config_file`
`--config=config_file`

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

`-d`
`--daemonize`

Run in the background. Without it, mamonsu will run in the foreground.

--version

Syntax:

```
mamonsu --version
```

Display `mamonsu` version.

--help

Syntax:

```
mamonsu --help
```

Display `mamonsu` command-line help.

Connection Options

connection_options provide command-line connection parameters for the target Postgres Pro cluster. *connection_options* can be `--host`, `--port`, `--dbname` (`-d`), `--username` (`-U`), and `--password` (`-W`). The `--dbname` option should specify the *mamonsu_database* created for monitoring purposes. Note that the `--username` (`-U`) option must specify a superuser that can access the cluster.

If you omit *connection_options*, mamonsu checks the configuration file for the needed settings.

Zabbix Server Actions

Using mamonsu, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show` *object_name*

Display the details about the specified template, host, or host group.

`id` *object_name*

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete` *object_id*

Delete the object with the specified ID.

`create` *hostgroup_name*
`create` *host_name hostgroup_id template_id mamonsu_address*

Create a new host or a host group.

`export` *template_name*

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items}` *host_id*

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- connection parameters
- logging parameters
- plugin parameters

All parameters must be specified in the *parameter = value* format.

Connection Parameters

[postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the mamonsu user set in bootstrap, or a superuser if `bootstrap` was not run.

Default: `postgres`

`password`

The password for the specified user.

`database`

The database to connect to for metrics collection.

Default: `postgres`

`host`

The server address to connect to.

Default: `localhost`

`port`

The port to connect to.

Default: 5432

`application_name`

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: `mamonsu`

`query_timeout`

statement_timeout for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

Alternatively you can specify environment variables rather than the configuration parameters. The following environment variables can be used: `PGUSER`, `PGPASSWORD`, `PGHOST`, `PGDATABASE`, `PGPORT`, and `PGAPPNAME`. See Section 37.15 for their meaning.

[system]

The `[system]` section controls system metrics collection and can contain the following parameters:

`enabled`

Enables/disables system metrics collection if set to `True` or `False`, respectively.

Default: `True`

[zabbix]

The `[zabbix]` section provides connection settings for the Zabbix server and can contain the following parameters:

`enabled`

Enables/disables sending the collected metrics data to the Zabbix server if set to `True` or `False`, respectively.

Default: `True`

`client`

The name of the Zabbix host.

`address`

The address of the Zabbix server.

Default: 127.0.0.1

`port`

The port of the Zabbix server.

Default: 10051

`timeout`

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

[agent]

The `[agent]` section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

`enabled`

Enables/disables metrics collection from the command line using the `agent` command.

Default: `True`

`host`

The address of the system on which mamonsu is running.

Default: 127.0.0.1

`port`

The port on which mamonsu is running.

Default: 10052

[sender]

The `[sender]` section controls the queue size of the data to be sent to the Zabbix server:

`queue`

The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

Logging Parameters

[metric_log]

The `[metric_log]` section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

`enabled`

Enables/disables storing the collected metrics data in a text file. If this option is set to `True`, mamonsu creates the `localhost.log` file for storing metric values.

Default: `False`

`directory`

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

`max_size_mb`

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

[log]

The `[log]` section specifies logging settings for mamonsu and can contain the following parameters:

`file`

Specifies the log filename, which can be preceded by the full path.

`level`

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

`format`

The format of the logged data.

Default: `[%(levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

Plugin Parameters

[plugins]

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in the section called “Individual Plugin Sections”.

Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the `Individual Plugin Sections` heading and edit its parameter values:

`enabled`

Enables/disables using built-in plugins if set to `True` or `False`, respectively. These values are case-sensitive.

Default: `False`

`interval`

Specifies the plugin operation interval, in seconds. The parameter is set with an integer specifying the plugin operation interval in seconds. You can set different intervals for different plugins. For plugins that collect PostgreSQL/ Postgres Pro metrics, for example, autovacuum, checkpoint, etc., this is the interval within which mamonsu accesses the Postgres Pro instance for metrics collection. For system plugins, for example, diskstats, memory, etc., this is the interval within which the operating system is accessed. For service plugins, for example, agentapi, logsender, zbxsender, this is the interval within which their functions are called. Note that the `interval` parameter of the zbxsender plugin is associated with the `timeout` parameter of the `[zabbix]` section. The maximum Zabbix server response timeout greater than the plugin operation interval may cause misbehavior of the zbxsender plugin: the plugin restarts with an error message if the connection or data transfer require longer time than the value specified in the `interval` parameter.

Default: 60

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

[preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to PREPARE TRANSACTION and Section 57.17.

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

[pgprobackup]

This plugin uses pg_probackup to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to pg_probackup.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified *`backup_directory`*.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

Usage

Collecting and Viewing Metrics Data

Once started, mamonsu begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]       7921004544    1564570818
system.memory[swap_cache]       868352    1564570818
pgsql.connections[idle]            6.0    1564570818
pgsql.archive_command[failed_trying_to_archive]    0    1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where *`metric_name`* is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at *https://www.zabbix.com/documentation/current/manual*.

If you have chosen to save all the collected metrics data into a file, as explained in the section called “Logging Parameters”, you can later upload these metrics onto a Zabbix server for visualization using the upload command.

Adding Custom Plugins

You can extend mamonsu with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

   ```
   [plugins]
   directory = /etc/mamonsu/plugins
   ```
3. Generate a new Zabbix template to include custom plugins:

   ```
   mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
   ```
4. Upload the generated `template.xml` to the Zabbix server as explained in the section called “Installation and Setup”.

Tuning Postgres Pro and System Configuration

Based on the collected metrics data, mamonsu can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See the section called “Command-Line Reference” for the full list of parameters available for `report` and `tune` commands.

Managing Zabbix Server Settings from the Command Line

mamonsu enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

   - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
   - Set the `ZABBIX_URL` to `http://zabbix/`

   If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

   ```
   --url=http://zabbix/ --user=zabbix_login --password=zabbix_password
   ```

2. Generate a new template file and upload it to the Zabbix server:

   ```
   mamonsu export template template.xml
   mamonsu zabbix template export template.xml
   ```

3. Create a new host group:

   ```
   mamonsu zabbix hostgroup create hostgroup_name
   ```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

   ```
   mamonsu zabbix hostgroup id hostgroup_name
   mamonsu zabbix template id template_name
   ```

5. Create a host associated with this group and link it with the uploaded template using a single command:

   ```
   mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
   ```

   where *`host_name`* is the name of the host, *`hostgroup_id`* and *`template_id`* are the unique IDs returned in the previous step, and *`mamonsu_address`* is the IP address of the system on which mamonsu runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in the section called “Installation and Setup”.

Exporting Metrics for Native Zabbix Agent

Using mamonsu, you can convert system and Postgres Pro metrics definitions to the format supported by the native *Zabbix agent*.

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

> **Important**
>
> To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by mamonsu using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

   ```
   mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
   ```

   For all possible options of the `export zabbix-parameters` command, see the section called “Command-Line Reference”.

2. Generate a template for the native Zabbix agent:

   ```
   mamonsu export zabbix-template template.xml
   ```

   For all possible options of the `export zabbix-template` command, see the section called “Command-Line Reference”.

3. Upload the generated template to the Zabbix server, as explained in the section called “Installation and Setup”.

4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:

   - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
   - For `{$PG_PATH}`, specify psql installation directory.

Compatibility Considerations

If you want to upgrade mamonsu to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:

  1. Install the new version of mamonsu.
  2. Generate a new template for the Zabbix server.
  3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
  4. Upload the new template to the Zabbix server.
  5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
  6. Create a new host for the same system and link the new template to it.
  7. Restart mamonsu. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.

- If you do not need to retain the collected data, do the following:

  1. Install the new version of mamonsu.
  2. Generate a new template for the Zabbix server.

3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
4. Upload the new template to the Zabbix server.
5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

pgpro_controldata

pgpro_controldata — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

Synopsis

`pgpro_controldata` [*option*...]

Description

`pgpro_controldata` prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

`pgpro_controldata` also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

pgpro_controldata is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-controldata` (for the detailed installation instructions, see Chapter 17).

Options

`pgpro_controldata` accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like pg_controldata does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

General-Purpose

`-B`
`--bindir`

Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D` *datadir*
`--pgdata=`*datadir*

Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`
`--version`

Print the pgpro_controldata version, then exit.

`-?`
`--help`

Show help about pgpro_controldata command-line arguments, then exit.

Compatibility-Related

`-C`
`--compatibility-check`

Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`
`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`
`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

Environment

`PGDATA`

Default data directory location

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

See Also

pg_controldata

pg_integrity_check

pg_integrity_check — calculate and validate checksums for controlled files (certified edition only)

Synopsis

`pg_integrity_check` [*connection-option*...] [-s | --system] [-u | --user] [-c | --catalog] [-o | --output] [-l *filename* | --log=*filename*] [--syslog] [-D *datadir*] [-C *filename*] [-v | --verbose] [-? | --help]

Description

`pg_integrity_check` is a utility provided with Postgres Pro Enterprise that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `-s`, `-u`, or `-c` for read-only files, additional files, or system catalog tables, respectively.

If you use the `-o` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `-o` option together with the `-s` option, since a checksum for read-only files cannot be overwritten.

If you omit the `-o` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see Section 33.2.

Options

connection-options

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `-c` option. For detailed description of connection options, see psql.

`-s`
`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`
`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`
`--catalog`

Validate checksums for system catalog tables. For the `-c` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

`-o`
`--output`

Recalculate checksums and write it into a file.

`-l` *filename*
`--log=`*filename*

Write checksum validation results into a log file.

`--syslog`

Write checksum validation results into the syslog.

`-D` *`datadir`*

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `-u` option.

`-C` *`filename`*

The absolute path to the configuration file used for integrity checks of system catalog tables of the selected database. If used with the `-o` option, `pg_integrity_check` writes into the specified file. If no other option is used, `pg_integrity_check` checks data against the specified file.

`-v`
`--verbose`

Print debugging information, including checksum values.

`-?`
`--help`

Print command-line help.

Return Values

0 — checksums are calculated or validated successfully.

1 — an error occurred during the initial checksum calculation for read-only files.

2 — checksum validation revealed changes in one or more of the controlled objects.

3 — an unexpected error occurred during checksum validation.

Examples

Compute checksums for additional files and write them into the `share/security/_var_lib_pgpro_ent-16_data.user.conf` configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/ent-16/data
```

Check integrity of all controlled objects in the `postgres` database on behalf of the `postgres` user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/ent-16/data -d postgres -h localhost -p
 5432 -U postgres
```

I.4. Third-Party Server Applications

This section covers third-party server-related applications. They are typically run on the host where the database server resides.

pgbouncer

pgbouncer — a Postgres Pro connection pooler

Synopsis

On Linux systems:

`pgbouncer` [-d] [-R] [-v] [-u *`user`*] pgbouncer.ini

`pgbouncer` -V | -h

On Windows:

`pgbouncer` [-v] [-u *`user`*] pgbouncer.ini

`pgbouncer` -V | -h

To use pgbouncer as a Windows service:

`pgbouncer.exe` --regservice pgbouncer.ini

`pgbouncer.exe` --unregservice pgbouncer.ini

Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

Quick Start

pgbouncer is provided with Postgres Pro Enterprise as a separate pre-built package `pgbouncer` (for the detailed installation instructions, see Chapter 17). Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch pgbouncer:

```
$ pgbouncer -d pgbouncer.ini
```

> **Note**
>
> The above command does not work on Windows systems. Instead, pgbouncer must be launched as a service that first needs to be registered, as follows:
>
> ```
> pgbouncer --regservice
> ```

4. Have your application (or the `psql` client) connect to pgbouncer instead of directly to the Postgres Pro server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage pgbouncer by connecting to the special administration database pgbouncer and issuing `SHOW HELP;` to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
  SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
  SET key = arg
  RELOAD
  PAUSE
  SUSPEND
  RESUME
  SHUTDOWN
  [...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to stderr after going into the background.

> **Note**
>
> Does not work on Windows, pgbouncer needs to run as service there.

`-R, --reboot`

> **Note**
>
> This option is deprecated. Instead of this option use a rolling restart with multiple pgbouncer processes listening on the same port using `so_reuseport` instead.

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

> **Note**
>
> Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

Admin Console

The console is available by connecting as normal to the database pgbouncer:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this.

Show Commands

The `SHOW` commands output information. Each command is described below.

SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

`database`

Statistics are presented per database.

`total_xact_count`

Total number of SQL transactions pooled by pgbouncer.

`total_query_count`

Total number of SQL queries pooled by pgbouncer.

`total_received`

Total volume in bytes of network traffic received by pgbouncer.

`total_sent`

Total volume in bytes of network traffic sent by pgbouncer.

`total_xact_time`

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

`total_query_time`

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

`total_wait_time`

Time spent by clients waiting for a server, in microseconds. Updated when a client connection is assigned a backend connection.

`avg_xact_count`

Average transactions per second in last stat period.

`avg_query_count`

Average queries per second in last stat period.

`avg_recv`

Average received (from clients) bytes per second.

`avg_sent`

Average sent (to clients) bytes per second.

`avg_xact_time`

Average transaction duration, in microseconds.

`avg_query_time`

Average query duration, in microseconds.

`avg_wait_time`

Average time spent by clients waiting for a server that were assigned a backend connection within the current `stats_period`, in microseconds (average per second within that period).

SHOW STATS_TOTALS

Subset of `SHOW STATS` showing the total values (`total_`).

SHOW STATS_AVERAGES

Subset of `SHOW STATS` showing the average values (`avg_`).

SHOW TOTALS

Like `SHOW STATS` but aggregated across all databases.

SHOW SERVERS

`type`

S, for server.

`user`

User name pgbouncer uses to connect to server.

`database`

Database name.

`state`

State of the pgbouncer server connection, one of `active`, `idle`, `used`, `tested`, `new`, `active_cancel`, or `being_canceled`.

`addr`

IP address of Postgres Pro server.

`port`

Port of Postgres Pro server.

`local_addr`

Connection start address on local machine.

`local_port`

Connection start port on local machine.

`connect_time`

When the connection was made.

`request_time`

When last request was issued.

`wait`

Not used for server connections.

`wait_us`

Not used for server connections.

`close_needed`

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.

`ptr`

Address of internal object for this connection. Used as unique ID.

`link`

Address of client connection the server is paired with.

`remote_pid`

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

`tls`

A string with TLS connection information, or empty if not using TLS.

`application_name`

A string containing the `application_name` set on the linked client connection, or empty if this is not set, or if there is no linked connection.

SHOW CLIENTS

`type`

C, for client.

`user`

Client connected user.

`database`

Database name.

`state`

State of the client connection, one of `active`, `waiting`, `active_cancel_req`, or `waiting_cancel_req`.

`addr`

IP address of the client.

`port`

Source port of the client.

`local_addr`

Connection end address on local machine.

`local_port`

Connection end port on local machine.

`connect_time`

Timestamp of connect time.

`request_time`

Timestamp of latest client request.

`wait`

Current waiting time in seconds.

`wait_us`

Microsecond part of the current waiting time.

`close_needed`

Not used for clients.

`ptr`

Address of internal object for this connection. Used as unique ID.

`link`

Address of server connection the client is paired with.

`remote_pid`

Process ID, in case client connects over Unix socket and OS supports getting it.

`tls`

A string with TLS connection information, or empty if not using TLS.

`application_name`

A string containing the `application_name` set by the client for this connection, or empty if this is not set.

SHOW POOLS

A new pool entry is made for each couple of (database, user).

`database`

Database name.

`user`

User name.

`cl_active`

Client connections that are either linked to server connections or are idle with no queries waiting to be processed.

`cl_waiting`

Client connections that have sent queries but have not yet got a server connection.

`cl_active_cancel_req`

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

`cl_waiting_cancel_req`

Client connections that have not forwarded query cancellations to the server yet.

`sv_active`

Server connections that are linked to a client.

`sv_active_cancel`

Server connections that are currently forwarding a cancel request.

`sv_being_canceled`

Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.

`sv_idle`

Server connections that are unused and immediately usable for client queries.

`sv_used`

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

`sv_tested`

Server connections that are currently running either `server_reset_query` or `server_check_query`.

`sv_login`

Server connections currently in the process of logging in.

`maxwait`

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

`maxwait_us`

Microsecond part of the maximum waiting time.

`pool_mode`

The pooling mode in use.

SHOW PEER_POOLS

A new `peer_pool` entry is made for each configured peer.

`database`

ID of the configured peer entry.

`cl_active_cancel_req`

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

`cl_waiting_cancel_req`

Client connections that have not forwarded query cancellations to the server yet.

`sv_active_cancel`

Server connections that are currently forwarding a cancel request.

`sv_login`

Server connections currently in the process of logging in.

SHOW LISTS

Show following internal information, in columns (not rows):

`databases`

Count of databases.

`users`

Count of users.

`pools`

Count of pools.

`free_clients`

Count of free clients.

`used_clients`

Count of used clients.

`login_clients`

Count of clients in `login` state.

`free_servers`

Count of free servers.

`used_servers`

Count of used servers.

`dns_names`

Count of DNS names in the cache.

`dns_zones`

Count of DNS zones in the cache.

`dns_queries`

Count of in-flight DNS queries.

`dns_pending`

Not used.

SHOW USERS

`name`

The user name.

`pool_mode`

The user's override `pool_mode`, or `NULL` if the default will be used instead.

SHOW DATABASES

`name`

Name of configured database entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`database`

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override pool_mode, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

`paused`

1 if this database is currently paused, else 0.

`disabled`

1 if this database is currently disabled, else 0.

SHOW PEERS

`peer_id`

ID of the configured peer entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`pool_size`

Maximum number of server connections that can be made to this peer.

SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

> **Note**
>
> This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

`fd`

File descriptor numeric value.

`task`

One of `pooler`, `client` or `server`.

`user`

User of the connection using the FD.

`database`

Database of the connection using the FD.

`addr`

IP address of the connection using the FD, `unix` if a Unix socket is used.

`port`

Port used by the connection using the FD.

`cancel`

Cancel key for this connection.

`link`

File descriptor for corresponding server/client. `NULL` if idle.

SHOW SOCKETS, SHOW ACTIVE_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

SHOW CONFIG

Show the current configuration settings, one per row, with the following columns:

`key`

Configuration variable name.

`value`

Configuration value.

`default`

Configuration default value.

`changeable`

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

SHOW MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

SHOW DNS_HOSTS

Show host names in DNS cache.

`hostname`

Host name.

`ttl`

How many seconds until next lookup.

`addrs`

Comma separated list of addresses.

SHOW DNS_ZONES

Show DNS zones in cache.

`zonename`

Zone name.

`serial`

Current serial.

`count`

Host names belonging to this zone.

SHOW VERSION

Show the pgbouncer version string.

SHOW STATE

Show the pgbouncer state settings. Current states are active, paused and suspended.

Process Controlling Commands

PAUSE [*db*]

pgbouncer tries to disconnect from all servers. Disconnecting each server connection waits for that server connection to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all server connections have been disconnected. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

DISABLE *db*

Reject all new client connections on the given database.

ENABLE *db*

Allow new client connections after a previous `DISABLE` command.

RECONNECT *db*

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed,

because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

KILL *db*

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

SUSPEND

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

RESUME [*db*]

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

SHUTDOWN

The pgbouncer process will exit.

RELOAD

The pgbouncer process will reload its configuration files and update changeable settings. This includes the main configuration file as well as the files specified by the settings `auth_file` and `auth_hba_file`.

pgbouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

WAIT_CLOSE [*db*]

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see the section called “SHOW SERVERS”). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

Other Commands

SET *key* = *arg*

Changes a configuration setting (see also the section called “SHOW CONFIG”). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

Signals

`SIGHUP`

Reload config. Same as issuing the command `RELOAD` on the console.

`SIGINT`

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

`SIGTERM`

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

`SIGUSR1`

Same as issuing `PAUSE` on the console.

`SIGUSR2`

Same as issuing `RESUME` on the console.

Libevent Settings

From the libevent documentation:

> It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.
>
> By setting the environment variable `EVENT_SHOW_METHOD`, `libevent` displays the kernel notification method that it uses.

`pgbouncer.ini` Configuration File

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

Generic Settings

`logfile`

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation, `kill -HUP` or on console `RELOAD;` should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to stderr. Use the command-line option `-q` or `-d` for that.

Default: not set

`pidfile`

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

`listen_addr`

Specifies a list (comma-separated) of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

`listen_port`

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

`unix_socket_dir`

Specifies the location for Unix sockets. Applies to both the listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with `@` specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: `/tmp` (empty on Windows)

`unix_socket_mode`

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

`unix_socket_group`

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

`user`

If set, specifies the Unix user to change to after startup. Works only if pgbouncer is started as root or if it's already running as the given user.

Not supported on Windows.

Default: not set

`pool_mode`

Specifies when a server connection can be reused by other clients.

`session`

Server is released back to pool after client disconnects. Default.

`transaction`

Server is released back to pool after transaction finishes.

`statement`

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

`max_client_conn`

Maximum number of client connections allowed.

When this setting is increased, then the file descriptor limits in the operating system might also have to be increased. Note that the number of file descriptors potentially used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

```
max_client_conn + (max pool_size * total databases * total users)
```

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

```
max_client_conn + (max pool_size * total databases)
```

The theoretical maximum should never be reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves the behavior when the normal load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool (see `reserve_pool_timeout`). The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this time, pgbouncer enables use of additional connections from the reserve pool. The 0 value disables this parameter. [seconds]

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the pgbouncer database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the pgbouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is a round-robin system behind a database address (TCP, DNS, or host list), then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

`track_extra_parameters`

By default, pgbouncer tracks `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings` and `application_name` parameters per client. To allow other parameters to be tracked, they can be specified here, so that pgbouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list (e.g. `default_transaction_read-only, IntervalStyle`)

> **Note**
>
> Most parameters cannot be tracked this way. The only parameters that can be tracked are ones that Postgres Pro reports to the client. Postgres Pro has an official list of parameters that it reports to the client. Postgres Pro extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing paremeters that Postgres Pro does not report. Notably Citus 12.0+ causes PostgreSQL to also report `search_path`.

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the `options` startup packet. Parameters specified using both of these methods are supported by `track_extra_parameters`. However, it's not possible to include `options` itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: `IntervalStyle`

`ignore_startup_parameters`

By default, pgbouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that pgbouncer knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list (e.g. `options,extra_float_digits`).

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the `options` startup packet. Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It's even possible to include `options` itself in `ignore_startup_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

Default: empty

`peer_id`

The peer ID used to identify this pgbouncer process in a group of pgbouncer processes that are peered together. The `peer_id` value should be unique within a group of peered pgbouncer processes. When set to 0, pgbouncer peering is disabled. See also [peers] Section for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

`disable_pqexec`

Disable the Simple Query protocol (PQexec). Unlike the Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously, this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only at the start of a connection. If `application_name` is later changed with `SET`, pgbouncer does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make pgbouncer use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for `service_name`.

`stats_period`

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

Authentication Settings

pgbouncer handles its own client authentication and has its own database of users. These settings control this.

`auth_type`

How to authenticate users.

`cert`

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

`md5`

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

`scram-sha-256`

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client

but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

`plain`

The clear-text password is sent over the wire. Deprecated.

`trust`

No authentication is done. The user name must still exist in `auth_file`.

`any`

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

`hba`

The actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods for different access paths, for example: connections over Unix socket use `peer` authentication method, connections over TCP must use TLS.

`pam`

Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name reported to PAM is `pgbouncer`. `pam` is not supported in the HBA configuration file.

`auth_hba_file`

HBA configuration file to use when `auth_type` is `hba`.

Default: not set

`auth_file`

The name of the file to load user names and passwords from. See the section called “Authentication File Format” for details.

Most authentication types (see `auth_type`) require that either `auth_file` or `auth_user` be set; otherwise there would be no users defined.

Default: not set

`auth_user`

If `auth_user` is set, then any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database, using `auth_user`. The password of `auth_user` will be taken from `auth_file`. (If `auth_user` does not require a password, then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

`auth_query`

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT usename, passwd FROM pg_shadow WHERE usename=$1`

`auth_dbname`

Database name in the [databases] section to be used for authentication purposes. This option can be either global or overriden in the connection string if this parameter is specified.

Log Settings

`syslog`

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

`syslog_ident`

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

`syslog_facility`

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

`log_connections`

Log successful logins.

Default: 1

`log_disconnections`

Log disconnections with reasons.

Default: 1

`log_pooler_errors`

Log error messages the pooler sends to clients.

Default: 1

`log_stats`

Write aggregated statistics into the log, every `stats_period`. This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

`verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. For example, using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

Console Access Control

`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when `auth_type` is `any`, in which case any user name is allowed in as admin.

Default: empty

`stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

Connection Sanity Checks, Timeouts

`server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress, so the value should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL`, which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, because in that mode, clients must not use any session-based features, since each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL`

`server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running `server_check_query` on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `select 1`

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a

configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused (not currently linked to any client connection) server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be closed. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login don't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login to the server failed, because of failure to connect or from authentication, the pooler waits this much before retrying to connect. During the waiting interval, new clients trying to connect to the failing server will get an error immediately without another connection attempt. [seconds]

The purpose of this behavior is that clients don't unnecessarily queue up waiting for a server connection to become available if the server is not working. However, it also means that if a server is momentarily failing, for example during a restart or if the configuration was erroneous, then it will take at least this long until the pooler will consider connecting to it again. Planned events such as restarts should normally be managed using the `PAUSE` command to avoid this.

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via "*") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long DNS lookups can be cached. The actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long DNS errors and `NXDOMAIN` DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, its connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not pgbouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate pgbouncer uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3), `secure` (tlsv1.2,tlsv1.3), `legacy` (all).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default`/`secure`, `compat`/`legacy`, `insecure`/`all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. The default mode is `prefer`.

`disable`

Plain TCP. TLS is not even requested from the server.

`prefer`

TLS connection is always requested first from Postgres Pro. If refused, the connection will be established over plain TCP. Server certificate is not validated. Default.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3), `secure` (tlsv1.2,tlsv1.3), `legacy` (all).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default`/`secure`, `compat`/`legacy`, `insecure`/`all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. The 0 value disables this parameter. If this is disabled, clients will be queued indefinitely. [seconds]

This setting is used to prevent unresponsive servers from grabbing up connections. It also helps when the server is down or rejects connections for any reason.

Default: 120.0

`cancel_wait_timeout`

Maximum time cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. 0 disables. If this is disabled, cancel requests will be queued indefinitely. [seconds]

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Default: 10.0

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

`idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

`suspend_timeout`

How long to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed. [seconds]

Default: 10

Low-Level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. The full result set can be larger.

Default: 2147483647

`listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in the queue. When the queue is full, further new connections are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

To make sure query cancellations keep working, you should set up pgbouncer peering between the different pgbouncer processes. For details see the `peer_id` configuration option and the `[peers]` configuration section. There's also an example that uses peering and `so_reuseport` in the Examples section.

Default: 0

`tcp_defer_accept`

Sets the `TCP_DEFER_ACCEPT` socket option; see `man 7 tcp` for details. (This is a Boolean option: 1 means enabled. The actual value set if enabled is currently hardcoded to 45 seconds.)

This is currently only supported on Linux.

Default: 1 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **tcp_keepidle=7200**, **tcp_keepintvl=75**, **tcp_keepcnt=9**. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

Section [databases]

The section `[databases]` defines the names of the databases that clients of pgbouncer can connect to and specifies where those connections will be routed. The section contains key=value lines like

```
dbname = connection string
```

where the key will be taken as a database name and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
foodb = host=host1.example.com port=5432
```

```
bardb = host=localhost dbname=bazdb
```

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where "" is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

`*` acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to pgbouncer specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in a round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

A comma-separated list of host names or addresses can be specified. In that case, connections are made in a round-robin manner. (If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. This is an implementation dependency that is subject to change.) Note that in a list, all hosts must be available at all times: there are no mechanisms to skip unreachable hosts or to select only available hosts from a list or similar. (This is different from what a host list in libpq means.) Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` for how clients are assigned to already established server connections.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise pgbouncer logs into the destination database with the client user name, meaning that there will be one pool per user.

`password`

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

`auth_user`

Override of the global `auth_user` setting, if specified.

`pool_size`

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

`min_pool_size`

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

`reserve_pool`

Set additional connections for this database. If not set, `reserve_pool_size` is used.

`connect_query`

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

`pool_mode`

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

`max_db_connections`

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

`client_encoding`

Ask specific `client_encoding` from server.

`datestyle`

Ask specific `datestyle` from server.

`timezone`

Ask specific `timezone` from server.

Section [users]

This section contains key=value lines like

```
user1 = settings
```

where the key will be taken as a user name and the value as a list of configuration settings specific for this user.

Example:

```
user1 = pool_mode=session
```

Only a few settings are available here.

`pool_mode`

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

Section [peers]

This section defines the peers that pgbouncer can forward cancellation requests to and where those cancellation requests will be routed.

pgbouncer processes can be peered together in a group by defining a `peer_id` value and a `[peers]` section in the configs of all the pgbouncer processes. These pgbouncer processes can then forward cancellation requests to the process that it originated from. This is needed to make cancellations work when multiple pgbouncer processes (possibly on different servers) are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains key=value lines like

```
peer_id = connection string
```

where the key will be taken as a `peer_id` and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
1 = host=host1.example.com
2 = host=/tmp/pgbouncer-2  port=5555
```

> **Note**
>
> For peering to work, the `peer_id` of each pgbouncer process in the group must be unique within the peered group. And the `[peers]` section should contain entries for each of those peer IDs. An example can be found in the Examples section. It is allowed, but not necessary, for the `[peers]` section to contain the `peer_id` of the pgbouncer that the config is for. Such an entry will be ignored, but it is allowed to make config management easier. Because it allows using the exact same `[peers]` section for multiple configs.

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it's not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```

`port`

Default: 6432

`pool_size`

If not set, the `default_pool_size` is used.

Include Directive

The pgbouncer configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the filename is not an absolute path, it is taken as relative to the current working directory.

Authentication File Format

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. pgbouncer ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

So user `admin` with password `1234` will have MD5-hashed password `md545f2603610af569b6155c45067268c6b`.

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in Section 20.1.

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.

- Database field: Supports `all`, `sameuser`, @*`file`*, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- User name field: Supports `all`, @*`file`*, multiple names. Not supported: `+groupname`.
- Address field: Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- Auth-method field: Only methods supported by pgbouncer's `auth_type` are supported, plus `peer` and `reject`, but except `any` and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

Examples

Small example configuration:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database examples:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb

; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
 datestyle=ISO
```

Example of a secure function for `auth_query`:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
 out phash text)
RETURNS record AS $$
BEGIN
    SELECT usename, passwd FROM pg_catalog.pg_shadow
    WHERE usename = i_username INTO uname, phash;
    RETURN;
END;$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

Example configs for 2 peered pgbouncer processes to create a multi-core pgbouncer setup using `so_reuseport`.

The config for the first process:

```
[databases]
postgres = host=localhost dbname=postgres
```

```
[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

The config for the second process:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

pg_filedump

pg_filedump — display formatted contents of a Postgres Pro heap, index, or control file

Synopsis

`pg_filedump` [*option*...] [*file*]

Description

pg_filedump is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the Options section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

Installation

pg_filedump is provided with Postgres Pro Enterprise as a separate pre-built package `pg-filedump-ent-16` (for the detailed installation instructions, see Chapter 17).

Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

`-a`

Display absolute addresses when formatting. Block header information is always block-relative.

`-b`

Display binary block images within a range. The option will turn off all formatting options.

`-d`

Display formatted block content dump. The option will turn off all other formatting options.

`-D` *attrlist*

Decode tuples using given comma-separated list of types. The list of supported types:

`bigint`
`bigserial`
`bool`
`char`
`charN` — char(n)
`date`
`float`
`float4`
`float8`
`int`
`json`
`macaddr`
`name`
`numeric`
`oid`
`real`

`serial`
`smallint`
`smallserial`
`text`
`time`
`timestamp`
`timetz`
`uuid`
`varchar`
`varcharN` — varchar(n)
`xid`
`xml`
`~` — ignore all attributes left in a tuple

`-f`

Display formatted block content dump along with interpretation.

`-h`

Display help.

`-i`

Display interpreted item details.

`-k`

Verify block checksums.

`-o`

Do not dump old values.

`-R` *`startblock`* `[`*`endblock`*`]`

Display specific block ranges within the file. Blocks are indexed from 0. *`startblock`*: block to start at. *`endblock`*: block to end at. A *`startblock`* without an *`endblock`* will format a single block.

`-s` *`segsize`*

Force segment size to *`segsize`*.

`-t`

Dump TOAST files.

`-v`

Output additional information about TOAST relations.

`-n` *`segnumber`*

Force segment number to *`segnumber`*.

`-S` *`blocksize`*

Force block size to *`blocksize`*.

`-x`

Force interpreted formatting of block items as index items.

`-y`

Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S` *`blocksize`*

Force block size to *`blocksize`*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

Appendix J. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

J.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Enterprise distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. A *list of language interfaces* is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

https://wiki.postgresql.org/wiki/List_of_drivers

J.2. Administration Tools

There are several administration tools available for Postgres Pro. One of them is PPEM, an integrated administration panel for Postgres Pro Enterprise management. It provides centralized privilege-based access to a unified management and monitoring interface with embedded command line. There are other solutions, e.g. an open-source platform *pgAdmin*.

J.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. A list of *procedural languages* is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

https://wiki.postgresql.org/wiki/PL_Matrix

J.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in Appendix F. Other extensions are developed independently, like *PostGIS*. Even Postgres Pro replication solutions can be developed externally. For example, *Slony-I* is a popular primary/standby replication solution that is developed independently from the core project. Some extensions are made compatible with Postgres Pro Enterprise, for example, citus. Consult the Postgres Pro Enterprise support team if you want to gain access to such extensions.

J.5. citus — distributed database and columnar storage functionality

citus is an extension that is made compatible with Postgres Pro and provides such major functionalities as columnar data storage and distributed OLAP database, which can be used either together or separately.

citus offers the following benefits:

- Columnar storage with data compression.

- The ability to scale your Postgres Pro installation to a distributed database cluster.
- Row-based or schema-based sharding.
- Parallelized DML operations across cluster nodes.
- Reference tables, which can be accessed locally on each node.
- The ability to execute DML queries on any node, which allows utilizing the full capacity of your cluster for distributed queries.

J.5.1. Limitations

citus is incompatible with some Postgres Pro Enterprise features, take note of these limitations while arranging your work with the extension:

- citus cannot be used together with autonomous transactions.
- With enable_self_join_removal set to `on`, query planning will result in an error if the optimizer decides to make the query distributed. Otherwise, the optimizer may form an erroneous distributed query plan and produce incorrect query results. Therefore, it is recommended to set this parameter to `off`.
- Real-time query replanning and citus should not be used together. If used, the `EXPLAIN ANALYZE` command may operate incorrectly.
- citus cannot operate with `standard_conforming_strings` set to `off`. citus_columnar can, but to avoid any errors, it is required to set the configuration parameter to `on` while executing the `CREATE EXTENSION` or `ALTER EXTENSION UPDATE` commands. After the installation or update is completed, you can change the parameter value to `off`, if necessary. The extension will continue to operate correctly.

J.5.2. Installation

The citus extension is provided with Postgres Pro Enterprise as a separate pre-built package `citus-ent-16` (for the detailed installation instructions, see Chapter 17). Once you have Postgres Pro Enterprise installed, follow the citus installation instructions below.

J.5.2.1. Installing citus on a Single Node

To enable citus on a single node, complete the following steps:

1. Add `citus` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'citus'
   ```

   If you want to use citus together with other extensions, citus should be the first on the list of `shared_preload_libraries`.

2. Reload the database server for the changes to take effect. To verify that the `citus` library was installed correctly, you can run the following command:

   ```
   SHOW shared_preload_libraries;
   ```

3. Create the citus extension using the following query:

   ```
   CREATE EXTENSION citus;
   ```

The `CREATE EXTENSION` command in the procedure above also installs the citus_columnar extension. If you want to enable *only* citus_columnar, complete the same steps but specify `citus_columnar` instead.

J.5.2.2. Installing citus on Multiple Nodes

To enable citus on multiple nodes, complete the following steps on all nodes:

1. Add `citus` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'citus'
```

If you want to use citus together with other extensions, citus should be the first on the list of `shared_preload_libraries`.

2. Set up access permissions to the database server. By default, the database server listens only to clients on `localhost`. Set the `listen_addresses` configuration parameter to `*` to specify all available IP interfaces.
3. Configure client authentication by editing the `pg_hba.conf` file.
4. Reload the database server for the changes to take effect. To verify that the `citus` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

5. Create the citus extension using the following query:

```
CREATE EXTENSION citus;
```

When the above steps have been taken on all nodes, perform the actions below on the coordinator node for worker nodes to be able to connect to it:

1. Register the hostname that worker nodes use to connect to the coordinator node:

```
SELECT citus_set_coordinator_host('coordinator_name', coordinator_port);
```

2. Add each worker node:

```
SELECT * from citus_add_node('worker_name', worker_port);
```

3. Verify that worker nodes are set successfully:

```
SELECT * FROM citus_get_active_worker_nodes();
```

J.5.3. When to Use citus

J.5.3.1. Multi-Tenant SaaS Database

Most B2B applications already have the notion of a tenant, customer, or account built into their data model. In this model, the database serves many tenants, each of whose data is separate from other tenants.

citus provides full SQL functionality for this workload and enables scaling out your relational database to more than 100,000 tenants. citus also adds new features for multi-tenancy. For example, citus supports tenant isolation to provide performance guarantees for large tenants, and has the concept of reference tables to reduce data duplication across tenants.

These capabilities allow you to scale out data of your tenants across many computers and add more CPU, memory, and disk resources. Further, sharing the same database schema across multiple tenants makes efficient use of hardware resources and simplifies database management.

citus offers the following advantages for multi-tenant applications:

- Fast queries for all tenants.
- Sharding logic in the database rather than the application.
- Hold more data in single-node Postgres Pro.
- Scale out maintaining the SQL functionality.
- Maintain performance under high concurrency.
- Fast metrics analysis across customer base.
- Scale to handle new customer sign-ups.
- Isolate resource usage of large and small customers.

J.5.3.2. Real-Time Analytics

citus supports real-time queries over large datasets. Commonly these queries occur in rapidly growing event systems or systems with time series data. Example use cases include:

- Analytic dashboards with sub-second response times.
- Exploratory queries on unfolding events.
- Large dataset archival and reporting.
- Analyzing sessions with funnel, segmentation, and cohort queries.

citus parallelizes query execution and scales linearly with the number of worker databases in a cluster. Some advantages of citus for real-time applications are as follows:

- Maintain sub-second responses as the dataset grows.
- Analyze new events and new data in real time.
- Parallelize SQL queries.
- Scale out maintaining the SQL functionality.
- Maintain performance under high concurrency.
- Fast responses to dashboard queries.
- Use one database rather than many on several nodes.
- Rich Postgres Pro data types and extensions.

J.5.3.3. Microservices

citus supports schema-based sharding, which allows distributing regular database schemas across many computers. This sharding methodology aligns well with typical microservices architecture, where storage is fully owned by the service hence cannot share the same schema definition with other tenants.

Schema-based sharding is an easier model to adopt, create a new schema, and set the `search_path` in your service.

Advantages of using citus for microservices:

- Allows distributing horizontally scalable state across services.
- Transfer strategic business data from microservices into common distributed tables for analytics.
- Efficiently use hardware by balancing services on multiple computers.
- Isolate noisy services to their own nodes.
- Easy to understand sharding model.
- Quick adoption.

J.5.3.4. Considerations for Use

citus extends Postgres Pro with distributed functionality, but it is not a drop-in replacement that scales out all workloads. A performant citus cluster involves thinking about the data model, tooling, and choice of SQL features used.

A good way to think about tools and SQL features is the following: if your workload aligns with use cases described here and you happen to run into an unsupported tool or query, then there is usually a good workaround.

J.5.3.5. When citus is Inappropriate

Some workloads do not need a powerful distributed database, while others require a large flow of information between worker nodes. In the first case citus is unnecessary and in the second not generally performant. Below are a few examples when you do not need to use citus:

- You do not expect your workload to ever grow beyond a single Postgres Pro Enterprise node.
- Offline analytics, without the need for real-time data transfer nor real-time queries.
- Analytics apps that do not need to support a large number of concurrent users.
- Queries that return data-heavy ETL results rather than summaries.

J.5.4. Quick Tutorials

J.5.4.1. Multi-Tenant Applications

In this tutorial a sample ad analytics dataset is used to demonstrate how you can use citus to power your multi-tenant application.

> **Note**
>
> This tutorial assumes that you already have citus installed and running. If not, consult the Installing citus on a Single Node section to set up the extension locally.

J.5.4.1.1. Data Model and Sample Data

This section shows how to create a database for an ad analytics app, which can be used by companies to view, change, analyze, and manage their ads and campaigns (see an *example app*). Such an application has good characteristics of a typical multi-tenant system. Data from different tenants is stored in a central database, and each tenant has an isolated view of their own data.

Three Postgres Pro tables to represent this data will be used. To get started, download sample data for these tables:

```
curl https://examples.citusdata.com/tutorial/companies.csv > companies.csv
curl https://examples.citusdata.com/tutorial/campaigns.csv > campaigns.csv
curl https://examples.citusdata.com/tutorial/ads.csv > ads.csv
```

J.5.4.1.2. Creating Tables

1. First connect to the citus coordinator using psql.

   If you are using citus installed as described in the Installing citus on a Single Node section, the coordinator node will be running on port `9700`.

   ```
   psql -p 9700
   ```

2. Create tables by using the standard Postgres Pro `CREATE TABLE` command:

   ```
   CREATE TABLE companies (
       id bigint NOT NULL,
       name text NOT NULL,
       image_url text,
       created_at timestamp without time zone NOT NULL,
       updated_at timestamp without time zone NOT NULL
   );

   CREATE TABLE campaigns (
       id bigint NOT NULL,
       company_id bigint NOT NULL,
       name text NOT NULL,
       cost_model text NOT NULL,
       state text NOT NULL,
       monthly_budget bigint,
       blacklisted_site_urls text[],
   ```

```
    created_at timestamp without time zone NOT NULL,
    updated_at timestamp without time zone NOT NULL
);

CREATE TABLE ads (
    id bigint NOT NULL,
    company_id bigint NOT NULL,
    campaign_id bigint NOT NULL,
    name text NOT NULL,
    image_url text,
    target_url text,
    impressions_count bigint DEFAULT 0,
    clicks_count bigint DEFAULT 0,
    created_at timestamp without time zone NOT NULL,
    updated_at timestamp without time zone NOT NULL
);
```

3. Create primary key indexes on each of the tables just like you would do in Postgres Pro:

```
ALTER TABLE companies ADD PRIMARY KEY (id);
ALTER TABLE campaigns ADD PRIMARY KEY (id, company_id);
ALTER TABLE ads ADD PRIMARY KEY (id, company_id);
```

J.5.4.1.3. Distributing Tables and Loading Data

Now you can instruct citus to distribute tables created above across the different nodes in the cluster. To do so, run the create_distributed_table function and specify the table you want to shard and the column you want to shard on. In the example below, all the tables are sharded on the `company_id` column.

```
SELECT create_distributed_table('companies', 'id');
SELECT create_distributed_table('campaigns', 'company_id');
SELECT create_distributed_table('ads', 'company_id');
```

Sharding all tables on the `company_id` column allows citus to co-locate the tables together and allows for features like primary keys, foreign keys, and complex joins across your cluster.

Then you can go ahead and load the downloaded data into the tables using the standard psql `\copy` command. Make sure that you specify the correct file path if you downloaded the file to a different location.

```
\copy companies from 'companies.csv' with csv
\copy campaigns from 'campaigns.csv' with csv
\copy ads from 'ads.csv' with csv
```

J.5.4.1.4. Running Queries

After the data is loaded into the tables, you can run some queries. citus supports standard `INSERT`, `UPDATE`, and `DELETE` commands for inserting and modifying rows in a distributed table, which is the typical way of interaction for a user-facing application.

For example, you can insert a new company by running:

```
INSERT INTO companies VALUES (5000, 'New Company', 'https://randomurl/image.png',
 now(), now());
```

If you want to double the budget for all campaigns of the company, run the `UPDATE` command:

```
UPDATE campaigns
SET monthly_budget = monthly_budget*2
WHERE company_id = 5;
```

Another example of such an operation is to run transactions, which span multiple tables. For example, you can delete a campaign and all its associated ads atomically by running:

```
BEGIN;
DELETE FROM campaigns WHERE id = 46 AND company_id = 5;
DELETE FROM ads WHERE campaign_id = 46 AND company_id = 5;
COMMIT;
```

Each statement in a transaction causes round-trips between the coordinator and workers in the multi-node citus. For multi-tenant workloads, it is more efficient to run transactions in distributed functions. The efficiency gains become more apparent for larger transactions, but you can use the small transaction above as an example.

1. First create a function that does the deletions:

   ```
   CREATE OR REPLACE FUNCTION
     delete_campaign(company_id int, campaign_id int)
   RETURNS void LANGUAGE plpgsql AS $fn$
   BEGIN
     DELETE FROM campaigns
      WHERE id = $2 AND campaigns.company_id = $1;
     DELETE FROM ads
      WHERE ads.campaign_id = $2 AND ads.company_id = $1;
   END;
   $fn$;
   ```

2. Next use the create_distributed_function function to instruct citus to call the function directly on workers rather than on the coordinator (except on a single-node citus installation, which runs everything on the coordinator). It calls the function on whatever worker holds the shards for the `ads` and `campaigns` tables corresponding to the `company_id` value.

   ```
   SELECT create_distributed_function(
     'delete_campaign(int, int)', 'company_id',
     colocate_with := 'campaigns'
   );

   -- You can run the function as usual
   SELECT delete_campaign(5, 46);
   ```

3. Besides transactional operations, you can also run analytics queries using standard SQL. One interesting query for a company to run is to see details about its campaigns with maximum budget.

   ```
   SELECT name, cost_model, state, monthly_budget
   FROM campaigns
   WHERE company_id = 5
   ORDER BY monthly_budget DESC
   LIMIT 10;
   ```

4. You can also run a join query across multiple tables to see information about running campaigns, which receive the most clicks and impressions.

   ```
   SELECT campaigns.id, campaigns.name, campaigns.monthly_budget,
          sum(impressions_count) AS total_impressions, sum(clicks_count) AS
    total_clicks
   FROM ads, campaigns
   WHERE ads.company_id = campaigns.company_id
   AND ads.campaign_id = campaigns.id
   AND campaigns.company_id = 5
   AND campaigns.state = 'running'
   GROUP BY campaigns.id, campaigns.name, campaigns.monthly_budget
   ORDER BY total_impressions, total_clicks;
   ```

The tutorial above shows how to use citus to power a simple multi-tenant application. As a next step, you can look at the Multi-Tenant Apps section to see how you can model your own data for multi-tenancy.

J.5.4.2. Real-Time Analytics

This tutorial demonstrates how to use citus to ingest events data and run analytical queries on that data in human real-time. A sample GitHub events dataset is used to this end in the example.

> **Note**
>
> This tutorial assumes that you already have citus installed and running. If not, consult the Installing citus on a Single Node section to set up the extension locally.

J.5.4.2.1. Data Model and Sample Data

This section shows how to create a database for a real-time analytics application. This application will insert large volumes of events data and enable analytical queries on that data with sub-second latencies. In this example, the GitHub events dataset is used. This dataset includes all public events on GitHub, such as `commits`, `forks`, `new issues`, and `comments` on these issues.

Two Postgres Pro tables are used to represent this data. To get started, download sample data for these tables:

```
curl https://examples.citusdata.com/tutorial/users.csv > users.csv
curl https://examples.citusdata.com/tutorial/events.csv > events.csv
```

J.5.4.2.2. Creating Tables

To start first connect to the citus coordinator using psql.

If you are using citus installed as described in the Installing citus on a Single Node section, the coordinator node will be running on port `9700`.

```
psql -p 9700
```

Then you can create the tables by using the standard Postgres Pro `CREATE TABLE` command:

```
CREATE TABLE github_events
(
    event_id bigint,
    event_type text,
    event_public boolean,
    repo_id bigint,
    payload jsonb,
    repo jsonb,
    user_id bigint,
    org jsonb,
    created_at timestamp
);

CREATE TABLE github_users
(
    user_id bigint,
    url text,
    login text,
    avatar_url text,
    gravatar_id text,
    display_login text
);
```

Next you can create indexes on events data just like you do in Postgres Pro. This example also shows how to create a GIN index to make querying on JSONB fields faster.

```
CREATE INDEX event_type_index ON github_events (event_type);
CREATE INDEX payload_index ON github_events USING GIN (payload jsonb_path_ops);
```

J.5.4.2.3. Distributing Tables and Loading Data

Now you can instruct citus to distribute the tables created above across the nodes in the cluster. To do so, you can call the create_distributed_table function and specify the table you want to shard and the column you want to shard on. In the example below, all the tables are sharded on the `user_id` column.

```
SELECT create_distributed_table('github_users', 'user_id');
SELECT create_distributed_table('github_events', 'user_id');
```

Sharding all tables on the `user_id` column allows citus to co-locate the tables together and allows for efficient joins and distributed roll-ups.

Then you can go ahead and load the downloaded data into the tables using the standard psql `\copy` command. Make sure that you specify the correct file path if you downloaded the file to a different location.

```
\copy github_users from 'users.csv' with csv
\copy github_events from 'events.csv' with csv
```

J.5.4.2.4. Running Queries

After the data is loaded into the tables, you can run some queries. First check how many users are contained in the distributed database.

```
SELECT count(*) FROM github_users;
```

Now analyze GitHub `push` events in the data. First compute the number of `commits` per minute by using the number of distinct `commits` in each `push` event.

```
SELECT date_trunc('minute', created_at) AS minute,
       sum((payload->>'distinct_size')::int) AS num_commits
FROM github_events
WHERE event_type = 'PushEvent'
GROUP BY minute
ORDER BY minute;
```

Also, there is a users table. You can also join the users with events and find the top ten users who created the most repositories.

```
SELECT login, count(*)
FROM github_events ge
JOIN github_users gu
ON ge.user_id = gu.user_id
WHERE event_type = 'CreateEvent' AND payload @> '{"ref_type": "repository"}'
GROUP BY login
ORDER BY count(*) DESC LIMIT 10;
```

citus also supports standard `INSERT`, `UPDATE`, and `DELETE` commands for inserting and modifying data. For example, you can update the user display login by running the following command:

```
UPDATE github_users SET display_login = 'no1youknow' WHERE user_id = 24305673;
```

As a next step, you can look at the Real-Time Apps section to see how you can model your own data and power real-time analytical applications.

J.5.4.3. Microservices

This tutorial shows how to use citus as the storage backend for multiple microservices and demonstrates a sample setup and basic operation of such a cluster.

> **Note**
>
> This tutorial assumes that you already have citus installed and running. If not, consult the Installing citus on a Single Node section to set up the extension locally.

J.5.4.3.1. Distributed Schemas

Distributed schemas are relocatable within a citus cluster. The system can rebalance them as a whole unit across the available nodes, which allows for efficient sharing of resources without manual allocation.

By design, microservices own their storage layer, we do not make any assumptions on the type of tables and data that they will create and store. We, however, provide a schema for every service and assume that they use a distinct role to connect to the database. When a user connects, their role name is put at the beginning of the `search_path`, so if the role matches the schema name, you do not need any application changes to set the correct `search_path`.

Three services are used in the example:

- `user` service
- `time` service
- `ping` service

To start first connect to the citus coordinator using psql.

If you are using citus installed as described in the Installing citus on a Single Node section, the coordinator node will be running on port `9700`.

```
psql -p 9700
```

You can now create the database roles for every service:

```
CREATE USER user_service;
CREATE USER time_service;
CREATE USER ping_service;
```

There are two ways to distribute a schema in citus:

- Manually by calling the `citus_schema_distribute('schema_name')` function:

  ```
  CREATE SCHEMA AUTHORIZATION user_service;
  CREATE SCHEMA AUTHORIZATION time_service;
  CREATE SCHEMA AUTHORIZATION ping_service;

  SELECT citus_schema_distribute('user_service');
  SELECT citus_schema_distribute('time_service');
  SELECT citus_schema_distribute('ping_service');
  ```

  This method also allows you to convert existing regular schemas into distributed schemas.

  > **Note**
  >
  > You can only distribute schemas that do not contain distributed and reference tables.

- Alternative approach is to enable the citus.enable_schema_based_sharding configuration parameter:

  ```
  SET citus.enable_schema_based_sharding TO ON;

  CREATE SCHEMA AUTHORIZATION user_service;
  CREATE SCHEMA AUTHORIZATION time_service;
  CREATE SCHEMA AUTHORIZATION ping_service;
  ```

  The parameter can be changed for the current session or permanently in the `postgresql.conf` file. With the parameter set to `ON` all created schemas are distributed by default.

You can list the currently distributed schemas:

```
SELECT * FROM citus_schemas;
```

```
schema_name  | colocation_id | schema_size | schema_owner
-------------+---------------+-------------+--------------
user_service |             5 | 0 bytes     | user_service
time_service |             6 | 0 bytes     | time_service
ping_service |             7 | 0 bytes     | ping_service
(3 rows)
```

J.5.4.3.2. Creating Tables

You now need to connect to the citus coordinator for every microservice. You can use the `\c` command to swap the user within an existing psql instance.

```
\c citus user_service
```

```
CREATE TABLE users (
    id SERIAL PRIMARY KEY,
    name VARCHAR(255) NOT NULL,
    email VARCHAR(255) NOT NULL
);
```

```
\c citus time_service
```

```
CREATE TABLE query_details (
    id SERIAL PRIMARY KEY,
    ip_address INET NOT NULL,
    query_time TIMESTAMP NOT NULL
);
```

```
\c citus ping_service
```

```
CREATE TABLE ping_results (
    id SERIAL PRIMARY KEY,
    host VARCHAR(255) NOT NULL,
    result TEXT NOT NULL
);
```

J.5.4.3.3. Configure Services

For the purpose of this tutorial a very simple set of services is used. You can obtain them by cloning this public repository:

```
git clone https://github.com/citusdata/citus-example-microservices.git
```

The repository contains the `ping`, `time`, and `user` services. All of them have the `app.py` file, which we run.

```
$ tree
.
├── LICENSE
├── README.md
├── ping
│   ├── app.py
│   ├── ping.sql
│   └── requirements.txt
├── time
│   ├── app.py
│   ├── requirements.txt
│   └── time.sql
└── user
    ├── app.py
    ├── requirements.txt
    └── user.sql
```

Before you run the services, however, edit the `user/app.py`, `ping/app.py`, and `time/app.py` files providing the *connection configuration* for your citus cluster:

```
# Database configuration
db_config = {
    'host': 'localhost',
    'database': 'citus',
    'user': 'ping_service',
    'port': 9700
}
```

After making the changes save all modified files and move on to the next step of running the services.

J.5.4.3.4. Running the Services

- Change into every app directory and run them in their own `python` environment.

  ```
  cd user
  pipenv install
  pipenv shell
  python app.py
  ```

  Repeat the above for the `time` and `ping` service, after which you can use the API.

- Create some users:

  ```
  curl -X POST -H "Content-Type: application/json" -d '[
    {"name": "John Doe", "email": "john@example.com"},
    {"name": "Jane Smith", "email": "jane@example.com"},
    {"name": "Mike Johnson", "email": "mike@example.com"},
    {"name": "Emily Davis", "email": "emily@example.com"},
    {"name": "David Wilson", "email": "david@example.com"},
    {"name": "Sarah Thompson", "email": "sarah@example.com"},
    {"name": "Alex Miller", "email": "alex@example.com"},
    {"name": "Olivia Anderson", "email": "olivia@example.com"},
    {"name": "Daniel Martin", "email": "daniel@example.com"},
    {"name": "Sophia White", "email": "sophia@example.com"}
  ]' http://localhost:5000/users
  ```

- List the created users:

  ```
  curl http://localhost:5000/users
  ```

- Get current time:

  ```
  curl http://localhost:5001/current_time
  ```

- Run the `ping` against example.com:

  ```
  curl -X POST -H "Content-Type: application/json" -d '{"host": "example.com"}'
   http://localhost:5002/ping
  ```

J.5.4.3.5. Exploring the Database

Now that we called some API functions, data has been stored and we can check if the citus_schemas view reflects what we expect:

```
SELECT * FROM citus_schemas;
```

```
schema_name  | colocation_id | schema_size | schema_owner
-------------+---------------+-------------+--------------
user_service |             1 | 112 kB      | user_service
time_service |             2 | 32 kB       | time_service
ping_service |             3 | 32 kB       | ping_service
```

```
(3 rows)
```

At the time of schemas creation you do not instruct citus on which computer to create them. It is done automatically. Execute the following query to see where each schema resides:

```
SELECT nodename,nodeport, table_name, pg_size_pretty(sum(shard_size))
  FROM citus_shards
GROUP BY nodename,nodeport, table_name;
```

```
nodename  | nodeport |         table_name          | pg_size_pretty
-----------+----------+-----------------------------+----------------
localhost |     9701 | time_service.query_details | 32 kB
localhost |     9702 | user_service.users         | 112 kB
localhost |     9702 | ping_service.ping_results  | 32 kB
```

We can see that the `time` service landed on node `localhost:9701`, while the `user` and `ping` services share space on the second worker `localhost:9702`. This is only an example, and the data sizes here can be ignored, but let us assume that we are annoyed by the uneven storage space utilization between the nodes. It makes more sense to have the two smaller `time` and `ping` services reside on one computer, while the large `user` service resides alone.

We can do this by instructing citus to rebalance the cluster by disk size:

```
SELECT citus_rebalance_start();
```

```
NOTICE:  Scheduled 1 moves as job 1
DETAIL:  Rebalance scheduled as background job
HINT:  To monitor progress, run: SELECT * FROM citus_rebalance_status();
 citus_rebalance_start
-----------------------
                     1
(1 row)
```

When done, check how the new layout looks:

```
SELECT nodename,nodeport, table_name, pg_size_pretty(sum(shard_size))
  FROM citus_shards
GROUP BY nodename,nodeport, table_name;
```

```
nodename  | nodeport |         table_name          | pg_size_pretty
-----------+----------+-----------------------------+----------------
localhost |     9701 | time_service.query_details | 32 kB
localhost |     9701 | ping_service.ping_results  | 32 kB
localhost |     9702 | user_service.users         | 112 kB
(3 rows)
```

We expect that the schemas have been moved and the cluster has become more balanced. This operation is transparent for the applications. Therefore, there is no need for a restart, and they will continue serving queries.

J.5.5. Use Case Guides

J.5.5.1. Multi-Tenant Applications

If you are building a Software-as-a-service (SaaS) application, you probably already have the notion of tenancy built into your data model. Typically, most information relates to tenants/customers/accounts and the database tables capture this natural relation.

For SaaS applications, each tenant's data can be stored together in a single database instance and kept isolated from and invisible to other tenants. This is efficient in three ways. First, application improvements apply to all clients. Second, sharing a database between tenants uses hardware efficiently. Last, it is much simpler to manage a single database for all tenants than a different database server for each tenant.

However, a single relational database instance has traditionally had trouble scaling to the volume of data needed for a large multi-tenant application. Developers were forced to relinquish the benefits of the relational model when data exceeded the capacity of a single database node.

The citus extension allows users to write multi-tenant applications as if they are connecting to a single Postgres Pro database, when in fact the database is a horizontally scalable cluster of computers. Client code requires minimal modifications and can continue to use full SQL capabilities.

This guide takes a sample multi-tenant application and describes how to model it for scalability with citus. Along the way typical challenges for multi-tenant applications are examined like isolating tenants from noisy neighbors, scaling hardware to accommodate more data, and storing data that differs across tenants. Postgres Pro and citus provide all the tools needed to handle these challenges, so let's get building.

J.5.5.1.1. Let's Make an App: Ad Analytics

We will build the back-end for an application that tracks online advertising performance and provides an analytics dashboard on top. It is a natural fit for a multi-tenant application because user requests for data concern one company (their own) at a time. Code for the full example application is *available* on GitHub.

Let's start by considering a simplified schema for this application. The application must keep track of multiple companies, each of which runs advertising campaigns. Campaigns have many ads, and each ad has associated records of its clicks and impressions.

Here is the example schema. We will make some minor changes later, which allow us to effectively distribute and isolate the data in a distributed environment.

```
CREATE TABLE companies (
  id bigserial PRIMARY KEY,
  name text NOT NULL,
  image_url text,
  created_at timestamp without time zone NOT NULL,
  updated_at timestamp without time zone NOT NULL
);

CREATE TABLE campaigns (
  id bigserial PRIMARY KEY,
  company_id bigint REFERENCES companies (id),
  name text NOT NULL,
  cost_model text NOT NULL,
  state text NOT NULL,
  monthly_budget bigint,
  blacklisted_site_urls text[],
  created_at timestamp without time zone NOT NULL,
  updated_at timestamp without time zone NOT NULL
);

CREATE TABLE ads (
  id bigserial PRIMARY KEY,
  campaign_id bigint REFERENCES campaigns (id),
  name text NOT NULL,
  image_url text,
  target_url text,
  impressions_count bigint DEFAULT 0,
  clicks_count bigint DEFAULT 0,
  created_at timestamp without time zone NOT NULL,
  updated_at timestamp without time zone NOT NULL
);
```

```
CREATE TABLE clicks (
  id bigserial PRIMARY KEY,
  ad_id bigint REFERENCES ads (id),
  clicked_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_click_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL
);

CREATE TABLE impressions (
  id bigserial PRIMARY KEY,
  ad_id bigint REFERENCES ads (id),
  seen_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_impression_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL
);
```

There are modifications we can make to the schema, which will give it a performance boost in a distributed environment like citus. To see how, we must become familiar with how the extension distributes data and executes queries.

J.5.5.1.2. Scaling the Relational Data Model

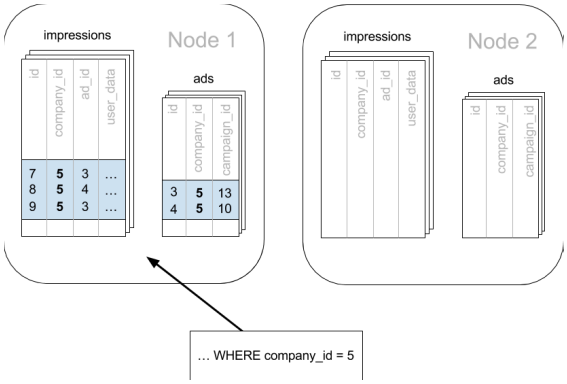
The relational data model is great for applications. It protects data integrity, allows flexible queries, and accommodates changing data. Traditionally the only problem was that relational databases were not considered capable of scaling to the workloads needed for big SaaS applications. Developers had to put up with NoSQL databases, or a collection of backend services, to reach that size.

With citus you can keep your data model *and* make it scale. The extension appears to applications as a single Postgres Pro database, but it internally routes queries to an adjustable number of physical servers (nodes), which can process requests in parallel.

Multi-tenant applications have a nice property that we can take advantage of: queries usually always request information for one tenant at a time, not a mix of tenants. For instance, when a salesperson is searching prospect information in a CRM, the search results are specific to his employer; other businesses' leads and notes are not included.

Because application queries are restricted to a single tenant, such as a store or company, one approach for making multi-tenant application queries fast is to store *all* data for a given tenant on the same node. This minimizes network overhead between the nodes and allows citus to support all your application's joins, key constraints and transactions efficiently. With this, you can scale across multiple nodes without having to totally re-write or re-architect your application. See the figure below to learn more.

Figure J.1. Multi-Tenant Ad Routing Diagram



This can be done in citus by making sure every table in our schema has a column to clearly mark which tenant owns which rows. In the ad analytics application the tenants are companies, so we must ensure all tables have a `company_id` column.

We can tell citus to use this column to read and write rows to the same node when the rows are marked for the same company. In citus terminology `company_id` is the *distribution column*, which you can learn more about in the Choosing Distribution Column section.

J.5.5.1.3. Preparing Tables and Ingesting Data

In the previous section we identified the correct distribution column for our multi-tenant application: `company_id`. Even in a single-computer database it can be useful to denormalize tables with the addition of `company_id`, whether it be for row-level security or for additional indexing. The extra benefit, as we saw, is that including the extra column helps for multi-machine scaling as well.

The schema we have created so far uses a separate `id` column as primary key for each table. citus requires that primary and foreign key constraints include the distribution column. This requirement makes enforcing these constraints much more efficient in a distributed environment as only a single node has to be checked to guarantee them.

In SQL, this requirement translates to making primary and foreign keys composite by including `company_id`. This is compatible with the multi-tenant case because what we really need there is to ensure uniqueness on a per-tenant basis.

Putting it all together, here are the changes that prepare the tables for distribution by `company_id`.

```
CREATE TABLE companies (
  id bigserial PRIMARY KEY,
  name text NOT NULL,
  image_url text,
  created_at timestamp without time zone NOT NULL,
  updated_at timestamp without time zone NOT NULL
);

CREATE TABLE campaigns (
  id bigserial,       -- was: PRIMARY KEY
  company_id bigint REFERENCES companies (id),
  name text NOT NULL,
  cost_model text NOT NULL,
  state text NOT NULL,
  monthly_budget bigint,
  blacklisted_site_urls text[],
  created_at timestamp without time zone NOT NULL,
  updated_at timestamp without time zone NOT NULL,
  PRIMARY KEY (company_id, id) -- added
);

CREATE TABLE ads (
  id bigserial,       -- was: PRIMARY KEY
  company_id bigint,  -- added
  campaign_id bigint, -- was: REFERENCES campaigns (id)
  name text NOT NULL,
  image_url text,
  target_url text,
  impressions_count bigint DEFAULT 0,
  clicks_count bigint DEFAULT 0,
  created_at timestamp without time zone NOT NULL,
  updated_at timestamp without time zone NOT NULL,
  PRIMARY KEY (company_id, id),         -- added
  FOREIGN KEY (company_id, campaign_id) -- added
```

```
    REFERENCES campaigns (company_id, id)
);

CREATE TABLE clicks (
  id bigserial,         -- was: PRIMARY KEY
  company_id bigint,    -- added
  ad_id bigint,         -- was: REFERENCES ads (id),
  clicked_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_click_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL,
  PRIMARY KEY (company_id, id),       -- added
  FOREIGN KEY (company_id, ad_id)     -- added
    REFERENCES ads (company_id, id)
);

CREATE TABLE impressions (
  id bigserial,          -- was: PRIMARY KEY
  company_id bigint,     -- added
  ad_id bigint,          -- was: REFERENCES ads (id),
  seen_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_impression_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL,
  PRIMARY KEY (company_id, id),        -- added
  FOREIGN KEY (company_id, ad_id)      -- added
    REFERENCES ads (company_id, id)
);
```

You can learn more about migrating your own data model in the Identify Distribution Strategy section.

J.5.5.1.3.1. Practical Example

> **Note**
>
> This guide is designed so you can follow along in your own citus database. This tutorial assumes that you already have the extension installed and running. If not, consult the Installing citus on a Single Node section to set up the extension locally.

1. At this point feel free to follow along in your own citus cluster by *downloading* and executing the SQL to create the schema. Once the schema is ready, we can tell citus to create shards on the workers. From the coordinator node run:

   ```
   SELECT create_distributed_table('companies',    'id');
   SELECT create_distributed_table('campaigns',    'company_id');
   SELECT create_distributed_table('ads',          'company_id');
   SELECT create_distributed_table('clicks',       'company_id');
   SELECT create_distributed_table('impressions', 'company_id');
   ```

   The create_distributed_table function informs citus that a table should be distributed among nodes and that future incoming queries to those tables should be planned for distributed execution. The function also creates shards for the table on worker nodes, which are low-level units of data storage citus uses to assign data to nodes.

2. The next step is loading sample data into the cluster from the command line:

   ```
   # Download and ingest datasets from the shell
   ```

```
for dataset in companies campaigns ads clicks impressions geo_ips; do
  curl -O https://examples.citusdata.com/mt_ref_arch/${dataset}.csv
done
```

3. Being an extension of Postgres Pro, citus supports bulk loading with the `/copy` command. Use it to ingest the data you downloaded and make sure that you specify the correct file path if you downloaded the file to some other location. Back inside psql run this:

```
\copy companies from 'companies.csv' with csv
\copy campaigns from 'campaigns.csv' with csv
\copy ads from 'ads.csv' with csv
\copy clicks from 'clicks.csv' with csv
\copy impressions from 'impressions.csv' with csv
```

J.5.5.1.4. Integrating Applications

Once you have made the slight schema modification outlined earlier, your application can scale with very little work. You will just connect the app to citus and let the database take care of keeping the queries fast and the data safe.

Any application queries or update statements, which include a filter on `company_id`, will continue to work exactly as they are. As mentioned earlier, this kind of filter is common in multi-tenant apps. When using an Object-Relational Mapper (ORM) you can recognize these queries by methods such as `where` or `filter`.

ActiveRecord:

```
Impression.where(company_id: 5).count
```

Django:

```
Impression.objects.filter(company_id=5).count()
```

Basically when the resulting SQL executed in the database contains a `WHERE company_id = :value` clause on every table (including tables in `JOIN` queries), then citus will recognize that the query should be routed to a single node and execute it there as it is. This makes sure that all SQL functionality is available. The node is an ordinary Postgres Pro server after all.

Also, to make it even simpler, you can use our *`activerecord-multi-tenant`* library for Ruby on Rails, or *`django-multitenant`* for Django, which will automatically add these filters to all your queries, even the complicated ones. Check out our migration guides for *Ruby on Rails* and *Django*.

This guide is framework-agnostic, so we will point out some citus features using SQL. Use your imagination for how these statements would be expressed in your language of choice.

Here is a simple query and update operating on a single tenant.

```
-- Campaigns with highest budget

SELECT name, cost_model, state, monthly_budget
  FROM campaigns
 WHERE company_id = 5
 ORDER BY monthly_budget DESC
 LIMIT 10;

-- Double the budgets!

UPDATE campaigns
   SET monthly_budget = monthly_budget*2
 WHERE company_id = 5;
```

A common pain point for users scaling applications with NoSQL databases is the lack of transactions and joins. However, transactions work as you would expect them to in citus:

```
-- Transactionally reallocate campaign budget money

BEGIN;

UPDATE campaigns
   SET monthly_budget = monthly_budget + 1000
 WHERE company_id = 5
   AND id = 40;

UPDATE campaigns
   SET monthly_budget = monthly_budget - 1000
 WHERE company_id = 5
   AND id = 41;

COMMIT;
```

As a final demo of SQL support, we have a query that includes aggregates and window functions and it works the same in citus as it does in Postgres Pro. The query ranks the ads in each campaign by the count of their impressions.

```
SELECT a.campaign_id,
       RANK() OVER (
         PARTITION BY a.campaign_id
         ORDER BY a.campaign_id, count(*) desc
       ), count(*) as n_impressions, a.id
  FROM ads as a
  JOIN impressions as i
    ON i.company_id = a.company_id
   AND i.ad_id      = a.id
 WHERE a.company_id = 5
GROUP BY a.campaign_id, a.id
ORDER BY a.campaign_id, n_impressions desc;
```

In short, when queries are scoped to a tenant then the `INSERT`, `UPDATE`, `DELETE`, complex SQL commands, and transactions all work as expected.

J.5.5.1.5. Sharing Data Between Tenants

Up until now all tables have been distributed by `company_id`, but sometimes there is data that can be shared by all tenants and does not “belong” to any tenant in particular. For instance, all companies using this example ad platform might want to get geographical information for their audience based on IP addresses. In a single computer database this could be accomplished by a lookup table for geo-ip, like the following. (A real table would probably use PostGIS, but bear with the simplified example.)

```
CREATE TABLE geo_ips (
  addrs cidr NOT NULL PRIMARY KEY,
  latlon point NOT NULL
    CHECK (-90  <= latlon[0] AND latlon[0] <= 90 AND
           -180 <= latlon[1] AND latlon[1] <= 180)
);
CREATE INDEX ON geo_ips USING gist (addrs inet_ops);
```

To use this table efficiently in a distributed setup, we need to find a way to co-locate the `geo_ips` table with clicks for not just one but every company. That way, no network traffic need be incurred at query time. This can be done in citus by designating `geo_ips` as a reference table.

```
-- Make synchronized copies of geo_ips on all workers
```

```
SELECT create_reference_table('geo_ips');
```

Reference tables are replicated across all worker nodes, and citus automatically keeps them in sync during modifications. Notice that we call the create_reference_table function rather than the create_distributed_table function.

Now that `geo_ips` is established as a reference table, load it with example data:

```
\copy geo_ips from 'geo_ips.csv' with csv
```

Now joining clicks with this table can execute efficiently. We can ask, for example, the locations of everyone who clicked on ad `290`.

```
SELECT c.id, clicked_at, latlon
  FROM geo_ips, clicks c
 WHERE addrs >> c.user_ip
   AND c.company_id = 5
   AND c.ad_id = 290;
```

J.5.5.1.6. Online Changes to the Schema

Another challenge with multi-tenant systems is keeping the schemas for all the tenants in sync. Any schema change needs to be consistently reflected across all the tenants. In citus, you can simply use standard Postgres Pro DDL commands to change the schema of your tables, and the extension will propagate them from the coordinator node to the workers using a two-phase commit protocol.

For example, the advertisements in this application could use a text caption. We can add a column to the table by issuing the standard SQL on the coordinator:

```
ALTER TABLE ads
  ADD COLUMN caption text;
```

This updates all the workers as well. Once this command finishes, the citus cluster will accept queries that read or write data in the new `caption` column.

For a fuller explanation of how DDL commands propagate through the cluster, see the Modifying Tables section.

J.5.5.1.7. When Data Differs Across Tenants

Given that all tenants share a common schema and hardware infrastructure, how can we accommodate tenants, which want to store information not needed by others? For example, one of the tenant applications using our advertising database may want to store tracking cookie information with clicks, whereas another tenant may care about browser agents. Traditionally databases using a shared schema approach for multi-tenancy have resorted to creating a fixed number of pre-allocated “custom” columns, or having external “extension tables”. However, Postgres Pro provides a much easier way with its unstructured column types, notably JSONB.

Notice that our schema already has a JSONB field in `clicks` called `user_data`. Each tenant can use it for flexible storage.

Suppose company five includes information in the field to track whether the user is on a mobile device. The company can query to find who clicks more, mobile or traditional visitors:

```
SELECT
  user_data->>'is_mobile' AS is_mobile,
  count(*) AS count
FROM clicks
WHERE company_id = 5
GROUP BY user_data->>'is_mobile'
```

```
ORDER BY count DESC;
```

The database administrator can even create a partial index to improve speed for an individual tenant's query patterns. Here is one to improve filters for clicks of the company with `company_id = 5` from users on mobile devices:

```
CREATE INDEX click_user_data_is_mobile
ON clicks ((user_data->>'is_mobile'))
WHERE company_id = 5;
```

Additionally, Postgres Pro supports GIN indices on JSONB. Creating a GIN index on a JSONB column will create an index on every key and value within that JSON document. This speeds up a number of JSONB operators such as `?`, `?|`, and `?&`.

```
CREATE INDEX click_user_data
ON clicks USING gin (user_data);

-- this speeds up queries like, "which clicks have
-- the is_mobile key present in user_data?"

SELECT id
  FROM clicks
 WHERE user_data ? 'is_mobile'
   AND company_id = 5;
```

J.5.5.1.8. Scaling Hardware Resources

Multi-tenant databases should be designed for future scale as business grows or tenants want to store more data. citus can scale out easily by adding new computers without having to make any changes or take application downtime.

Being able to rebalance data in the citus cluster allows you to grow your data size or number of customers and improve performance on demand. Adding new computers allows you to keep data in memory even when it is much larger than what a single computer can store.

Also, if data increases for only a few large tenants, then you can isolate those particular tenants to separate nodes for better performance.

To scale out your citus cluster, first add a new worker node to it with the citus_add_node function.

Once you add the node it is available in the system. However, at this point no tenants are stored on it and citus will not yet run any queries there. To move your existing data, you can ask citus to rebalance the data. This operation moves bundles of rows called shards between the currently active nodes to attempt to equalize the amount of data on each node.

```
SELECT citus_rebalance_start();
```

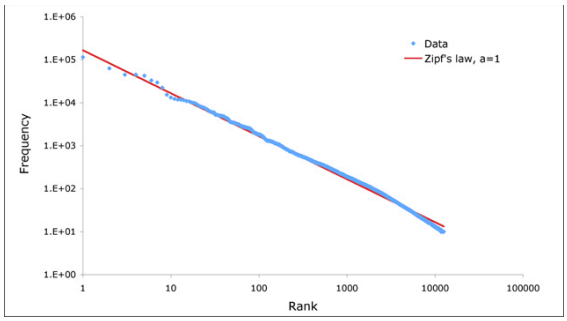
Applications do not need to undergo downtime during shard rebalancing. Read requests continue seamlessly, and writes are locked only when they affect shards, which are currently in flight. In citus writes to shards are blocked during rebalancing but reads are unaffected.

J.5.5.1.9. Dealing with Big Tenants

The previous section describes a general-purpose way to scale a cluster as the number of tenants increases. However, users often have two questions. The first is what will happen to their largest tenant if it grows too big. The second is what are the performance implications of hosting a large tenant together with small ones on a single worker node.

Regarding the first question, investigating data from large SaaS sites reveals that as the number of tenants increases, the size of tenant data typically tends to follow a *Zipfian distribution*. See the figure below to learn more.

Figure J.2. Ziphian Distribution



For instance, in a database of 100 tenants, the largest is predicted to account for about 20% of the data. In a more realistic example for a large SaaS company, if there are 10,000 tenants, the largest will account for around 2% of the data. Even at 10TB of data, the largest tenant will require 200GB, which can pretty easily fit on a single node.

Another question is regarding performance when large and small tenants are on the same node. Standard shard rebalancing will improve overall performance but it may or may not improve the mixing of large and small tenants. The rebalancer simply distributes shards to equalize storage usage on nodes, without examining which tenants are allocated on each shard.

To improve resource allocation and make guarantees of tenant QoS it is worthwhile to move large tenants to dedicated nodes. The citus extension provides the tools to do this.

In our case, let's imagine that the company with `company_id=5` is very large. We can isolate the data for this tenant in two steps. We will present the commands here, and you can consult the Tenant Isolation section to learn more about them.

First isolate the tenant's data to a dedicated shard suitable to move. The `CASCADE` option also applies this change to the rest of our tables distributed by `company_id`.

```
SELECT isolate_tenant_to_new_shard(
  'companies', 5, 'CASCADE'
);
```

The output is the shard ID dedicated to hold `company_id=5`:

```
┌─────────────────────────────────┐
│ isolate_tenant_to_new_shard │
├─────────────────────────────────┤
│                          102240 │
└─────────────────────────────────┘
```

Next we move the data across the network to a new dedicated node. Create a new node as described in the previous section. Take note of its hostname.

```
-- Find the node currently holding the new shard

SELECT nodename, nodeport
  FROM pg_dist_placement AS placement,
       pg_dist_node AS node
 WHERE placement.groupid = node.groupid
   AND node.noderole = 'primary'
   AND shardid = 102240;

-- Move the shard to your choice of worker (it will also move the
-- other shards created with the CASCADE option)
```

```
-- Note that you should set wal_level for all nodes to be >= logical
-- to use citus_move_shard_placement
-- You also need to restart your cluster after setting wal_level in
-- postgresql.conf files

SELECT citus_move_shard_placement(
  102240,
  'source_host', source_port,
  'dest_host', dest_port);
```

You can confirm the shard movement by querying the pg_dist_placement table again.

J.5.5.1.10. Where to Go From Here

With this, you now know how to use citus to power your multi-tenant application for scalability. If you have an existing schema and want to migrate it for citus, see the Migrating an Existing App section.

To adjust a front-end application, specifically Ruby on Rails or Django, read *Ruby on Rails* or *Django* migration guides.

J.5.5.2. Real-Time Dashboards

citus provides real-time queries over large datasets. One workload we commonly see at citus involves powering real-time dashboards of event data.

For example, you could be a cloud services provider helping other businesses monitor their HTTP traffic. Every time one of your clients receives an HTTP request your service receives a log record. You want to ingest all those records and create an HTTP analytics dashboard that gives your clients insights such as the number HTTP errors their sites served. It is important that this data shows up with as little latency as possible so your clients can fix problems with their sites. It is also important for the dashboard to show graphs of historical trends.

Alternatively, maybe you are building an advertising network and want to show clients clickthrough rates on their campaigns. In this example latency is also critical, raw data volume is also high, and both historical and live data are important.

In this section we will demonstrate how to build part of the first example, but this architecture would work equally well for the second and many other use cases.

J.5.5.2.1. Data Model

The data we are dealing with is an immutable stream of log data. We will insert directly into citus but it is also common for this data to first be routed through something like Kafka. Doing so has the usual advantages, and makes it easier to pre-aggregate the data once data volumes become unmanageably high.

We will use a simple schema for ingesting HTTP event data. This schema serves as an example to demonstrate the overall architecture; a real system might use additional columns.

```
-- This is run on the coordinator

CREATE TABLE http_request (
  site_id INT,
  ingest_time TIMESTAMPTZ DEFAULT now(),

  url TEXT,
  request_country TEXT,
  ip_address TEXT,

  status_code INT,
  response_time_msec INT
```

```
);

SELECT create_distributed_table('http_request', 'site_id');
```

When we call the create_distributed_table function we ask citus to hash-distribute `http_request` using the `site_id` column. That means all the data for a particular site will live in the same shard.

The user defined functions use the default configuration values for shard count. We recommend using 2-4x as many shards as CPU cores in your cluster. Using this many shards lets you rebalance data across your cluster after adding new worker nodes.

With this, the system is ready to accept data and serve queries. Keep the following loop running in a psql console in the background while you continue with the other commands in this article. It generates fake data every second or two.

```
DO $$
  BEGIN LOOP
    INSERT INTO http_request (
      site_id, ingest_time, url, request_country,
      ip_address, status_code, response_time_msec
    ) VALUES (
      trunc(random()*32), clock_timestamp(),
      concat('http://example.com/', md5(random()::text)),
      ('{China,India,USA,Indonesia}'::text[])[ceil(random()*4)],
      concat(
        trunc(random()*250 + 2), '.',
        trunc(random()*250 + 2), '.',
        trunc(random()*250 + 2), '.',
        trunc(random()*250 + 2)
      )::inet,
      ('{200,404}'::int[])[ceil(random()*2)],
      5+trunc(random()*150)
    );
    COMMIT;
    PERFORM pg_sleep(random() * 0.25);
  END LOOP;
END $$;
```

Once you are ingesting data, you can run dashboard queries such as:

```
SELECT
  site_id,
  date_trunc('minute', ingest_time) as minute,
  COUNT(1) AS request_count,
  SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as success_count,
  SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count,
  SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
FROM http_request
WHERE date_trunc('minute', ingest_time) > now() - '5 minutes'::interval
GROUP BY site_id, minute
ORDER BY minute ASC;
```

The setup described above works but has two drawbacks:

- Your HTTP analytics dashboard must go over each row every time it needs to generate a graph. For example, if your clients are interested in trends over the past year, your queries will aggregate every row for the past year from scratch.
- Your storage costs will grow proportionally with the ingest rate and the length of the queryable history. In practice, you may want to keep raw events for a shorter period of time (one month) and look at historical graphs over a longer time period (years).

J.5.5.2.2. Rollups

You can overcome both drawbacks by rolling up the raw data into a pre-aggregated form. Here, we will aggregate the raw data into a table, which stores summaries of 1-minute intervals. In a production system, you would probably also want something like 1-hour and 1-day intervals, these each correspond to zoom-levels in the dashboard. When the user wants request times for the last month the dashboard can simply read and chart the values for each of the last 30 days.

```
CREATE TABLE http_request_1min (
  site_id INT,
  ingest_time TIMESTAMPTZ, -- which minute this row represents

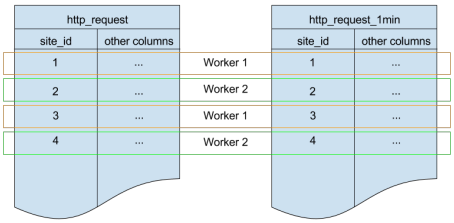
  error_count INT,
  success_count INT,
  request_count INT,
  average_response_time_msec INT,
  CHECK (request_count = error_count + success_count),
  CHECK (ingest_time = date_trunc('minute', ingest_time))
);

SELECT create_distributed_table('http_request_1min', 'site_id');

CREATE INDEX http_request_1min_idx ON http_request_1min (site_id, ingest_time);
```

This looks a lot like the previous code block. Most importantly: It also shards on `site_id` and uses the same default configuration for shard count. Because all three of those match, there is a 1-to-1 correspondence between `http_request` shards and `http_request_1min` shards, and citus will place matching shards on the same worker. This is called co-location; it makes queries such as joins faster and our rollups possible. See the figure below to learn more.

Figure J.3. Collocation Diagram



In order to populate `http_request_1min` we are going to periodically run `INSERT INTO SELECT`. This is possible because the tables are co-located. The following function wraps the rollup query up for convenience.

```
-- Single-row table to store when we rolled up last
CREATE TABLE latest_rollup (
  minute timestamptz PRIMARY KEY,

  -- "minute" should be no more precise than a minute
  CHECK (minute = date_trunc('minute', minute))
);

-- Initialize to a time long ago
INSERT INTO latest_rollup VALUES ('10-10-1901');

-- Function to do the rollup
CREATE OR REPLACE FUNCTION rollup_http_request() RETURNS void AS $$
DECLARE
  curr_rollup_time timestamptz := date_trunc('minute', now() - interval '1 minute');
```

```
  last_rollup_time timestamptz := minute from latest_rollup;
BEGIN
  INSERT INTO http_request_1min (
    site_id, ingest_time, request_count,
    success_count, error_count, average_response_time_msec
  ) SELECT
    site_id,
    date_trunc('minute', ingest_time),
    COUNT(1) as request_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as
 success_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count,
    SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
  FROM http_request
  -- Roll up only data new since last_rollup_time
  WHERE date_trunc('minute', ingest_time) <@
          tstzrange(last_rollup_time, curr_rollup_time, '(]')
  GROUP BY 1, 2;

  -- Update the value in latest_rollup so that next time we run the
  -- rollup it will operate on data newer than curr_rollup_time
  UPDATE latest_rollup SET minute = curr_rollup_time;
END;
$$ LANGUAGE plpgsql;
```

> **Note**
>
> The above function should be called every minute. You could do this by adding a `crontab` entry on the coordinator node:
>
> ```
> * * * * * psql -c 'SELECT rollup_http_request();'
> ```

Alternatively, an extension such as *pg_cron* allows you to schedule recurring queries directly from the database.

The dashboard query from earlier is now a lot nicer:

```
SELECT site_id, ingest_time as minute, request_count,
       success_count, error_count, average_response_time_msec
  FROM http_request_1min
 WHERE ingest_time > date_trunc('minute', now()) - '5 minutes'::interval;
```

J.5.5.2.3. Expiring Old Data

The rollups make queries faster, but we still need to expire old data to avoid unbounded storage costs. Simply decide how long you would like to keep data for each granularity and use standard queries to delete expired data. In the following example, we decided to keep raw data for one day, and per-minute aggregations for one month:

```
DELETE FROM http_request WHERE ingest_time < now() - interval '1 day';
DELETE FROM http_request_1min WHERE ingest_time < now() - interval '1 month';
```

In production you could wrap these queries in a function and call it every minute in a `cron` job.

Data expiration can go even faster by using table range partitioning on top of citus hash distribution. See the Timeseries Data section for a detailed example.

Those are the basics. We provided an architecture that ingests HTTP events and then rolls up these events into their pre-aggregated form. This way you can both store raw events and also power your analytical dashboards with subsecond queries.

The next sections extend upon the basic architecture and show you how to resolve questions, which often appear.

J.5.5.2.4. Approximate Distinct Counts

A common question in HTTP analytics deals with approximate distinct counts: How many unique visitors visited your site over the last month? Answering this question *exactly* requires storing the list of all previously seen visitors in the rollup tables, a prohibitively large amount of data. However, an approximate answer is much more manageable.

A datatype called HyperLogLog, or `hll`, can answer the query approximately; it takes a surprisingly small amount of space to tell you approximately how many unique elements are in a set. Its accuracy can be adjusted. We will use ones which, using only 1,280 bytes, will be able to count up to tens of billions of unique visitors with at most 2.2% error.

An equivalent problem appears if you want to run a global query, such as the number of unique IP addresses, which visited any of your client's sites over the last month. Without `hll` this query involves shipping lists of IP addresses from the workers to the coordinator for it to deduplicate. That is both a lot of network traffic and a lot of computation. By using `hll` you can greatly improve query speed.

You can install the hll extension, whose instructions are available in *the GitHub repository*, and enable it as follows:

```
CREATE EXTENSION hll;
```

Now we are ready to track IP addresses in our rollup with hll. First add a column to the rollup table.

```
ALTER TABLE http_request_1min ADD COLUMN distinct_ip_addresses hll;
```

Next use our custom aggregation to populate the column. Just add it to the query in our rollup function:

```
@@ -1,10 +1,12 @@
  INSERT INTO http_request_1min (
    site_id, ingest_time, request_count,
    success_count, error_count, average_response_time_msec
+   , distinct_ip_addresses
  ) SELECT
    site_id,
    date_trunc('minute', ingest_time),
    COUNT(1) as request_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as
 success_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count,
    SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
+   , hll_add_agg(hll_hash_text(ip_address)) AS distinct_ip_addresses
  FROM http_request
```

Dashboard queries are a little more complicated, you have to read out the distinct number of IP addresses by calling the `hll_cardinality` function:

```
SELECT site_id, ingest_time as minute, request_count,
       success_count, error_count, average_response_time_msec,
       hll_cardinality(distinct_ip_addresses) AS distinct_ip_address_count
  FROM http_request_1min
 WHERE ingest_time > date_trunc('minute', now()) - interval '5 minutes';
```

`hll` is not just faster, it lets you do things you could not previously. Say we did our rollups, but instead of using `hll` we saved the exact unique counts. This works fine, but you cannnot answer queries such as “how many distinct sessions were there during this one-week period in the past we've thrown away the raw data for?”.

With `hll`, this is easy. You can compute distinct IP counts over a time period with the following query:

```
SELECT hll_cardinality(hll_union_agg(distinct_ip_addresses))
FROM http_request_1min
WHERE ingest_time > date_trunc('minute', now()) - '5 minutes'::interval;
```

You can find more information about the hll extension in the *project's GitHub repository*.

J.5.5.2.5. Unstructured Data with JSONB

The citus extension works well with Postgres Pro built-in support for unstructured data types. To demonstrate this, let's keep track of the number of visitors, which came from each country. Using a semi-structure data type saves you from needing to add a column for every individual country and ending up with rows that have hundreds of sparsely filled columns. It is recommended to use the JSONB format, here we will demonstrate how to incorporate JSONB columns into your data model.

First, add the new column to our rollup table:

```
ALTER TABLE http_request_1min ADD COLUMN country_counters JSONB;
```

Next, include it in the rollups by modifying the rollup function:

```
@@ -1,14 +1,19 @@
  INSERT INTO http_request_1min (
    site_id, ingest_time, request_count,
    success_count, error_count, average_response_time_msec
+   , country_counters
  ) SELECT
    site_id,
    date_trunc('minute', ingest_time),
    COUNT(1) as request_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as success_count
    SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count
    SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
- FROM http_request
+   , jsonb_object_agg(request_country, country_count) AS country_counters
+ FROM (
+   SELECT *,
+     count(1) OVER (
+       PARTITION BY site_id, date_trunc('minute', ingest_time), request_country
+     ) AS country_count
+   FROM http_request
+ ) h
```

Now, if you want to get the number of requests that came from America in your dashboard, you can modify the dashboard query to look like this:

```
SELECT
  request_count, success_count, error_count, average_response_time_msec,
  COALESCE(country_counters->>'USA', '0')::int AS american_visitors
FROM http_request_1min
WHERE ingest_time > date_trunc('minute', now()) - '5 minutes'::interval;
```

J.5.5.3. Timeseries Data

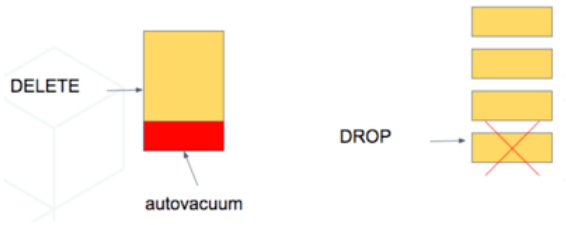
In a timeseries workload, applications (such as some real-time apps) query recent information, while archiving old information.

To deal with this workload, a single-node Postgres Pro database would typically use table partitioning to break a big table of time-ordered data into multiple inherited tables with each containing different time ranges.

Storing data in multiple physical tables speeds up data expiration. In a single big table, deleting rows incurs the cost of scanning to find which to delete, and then vacuuming the emptied space. On the other

hand, dropping a partition is a fast operation independent of data size. It is the equivalent of simply removing files on disk that contain the data. See the figure below to learn more.

Figure J.4. Delete vs. Drop Diagram



Partitioning a table also makes indices smaller and faster within each date range. Queries operating on recent data are likely to operate on “hot” indices that fit in memory. This speeds up reads. See the figure below to learn more.

Figure J.5. `SELECT` Across Multiple Indexes

Also inserts have smaller indices to update, so they go faster too. See the figure below to learn more.

Figure J.6. `INSERT` Across Multiple Indexes

Time-based partitioning makes most sense when:

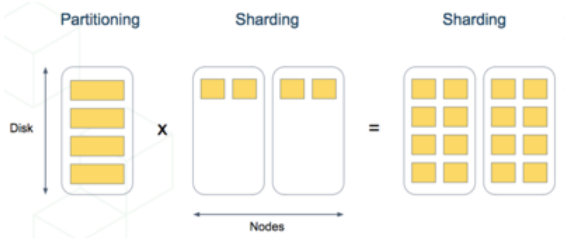
1. Most queries access a very small subset of the most recent data.
2. Older data is periodically expired (deleted/dropped).

Keep in mind that, in the wrong situation, reading all these partitions can hurt overhead more than it helps. However, in the right situations it is quite helpful. For example, when keeping a year of time series data and regularly querying only the most recent week.

J.5.5.3.1. Scaling Timeseries Data on citus

We can mix the single-node table partitioning techniques with citus distributed sharding to make a scalable time-series database. It is the best of both worlds. It is especially elegant atop Postgres Pro declarative table partitioning. See the figure below to learn more.

Figure J.7. Timeseries Sharding and Partitioning



For example, let's distribute *and* partition a table holding the historical *GitHub events data*.

Each record in this GitHub data set represents an event created in GitHub, along with key information regarding the event such as event type, creation date, and the user who created the event.

The first step is to create and partition the table by time as we would in a single-node Postgres Pro database:

```
-- Declaratively partitioned table
CREATE TABLE github_events (
  event_id bigint,
  event_type text,
  event_public boolean,
  repo_id bigint,
  payload jsonb,
  repo jsonb,
  actor jsonb,
  org jsonb,
  created_at timestamp
) PARTITION BY RANGE (created_at);
```

Notice the `PARTITION BY RANGE (created_at)`. This tells Postgres Pro that the table will be partitioned by the `created_at` column in ordered ranges. We have not yet created any partitions for specific ranges, though.

Before creating specific partitions, let's distribute the table in citus. We will shard by `repo_id`, meaning the events will be clustered into shards per repository.

```
SELECT create_distributed_table('github_events', 'repo_id');
```

At this point citus has created shards for this table across worker nodes. Internally each shard is a table with the name `github_events_`*`N`* for each shard identifier *`N`*. Also, citus propagated the partitioning information, and each of these shards has `Partition key: RANGE (created_at)` declared.

A partitioned table cannot directly contain data, it is more like a view across its partitions. Thus the shards are not yet ready to hold data. We need to create partitions and specify their time ranges, after which we can insert data that match the ranges.

J.5.5.3.2. Automating Partition Creation

citus provides helper functions for partition management. We can create a batch of monthly partitions using the create_time_partitions function:

```
SELECT create_time_partitions(
  table_name         := 'github_events',
  partition_interval := '1 month',
  end_at             := now() + '12 months'
);
```

citus also includes the time_partitions view for an easy way to investigate the partitions it has created.

```
SELECT partition
  FROM time_partitions
 WHERE parent_table = 'github_events'::regclass;
```

```
┌────────────────────────┐
│       partition        │
├────────────────────────┤
│ github_events_p2021_10 │
│ github_events_p2021_11 │
│ github_events_p2021_12 │
│ github_events_p2022_01 │
│ github_events_p2022_02 │
│ github_events_p2022_03 │
│ github_events_p2022_04 │
│ github_events_p2022_05 │
│ github_events_p2022_06 │
```

```
| github_events_p2022_07 |
| github_events_p2022_08 |
| github_events_p2022_09 |
| github_events_p2022_10 |
└────────────────────────┘
```

As time progresses, you will need to do some maintenance to create new partitions and drop old ones. It is best to set up a periodic job to run the maintenance functions with an extension like *pg_cron*:

```
-- Set two monthly cron jobs:

-- 1. Ensure we have partitions for the next 12 months

SELECT cron.schedule('create-partitions', '0 0 1 * *', $$
  SELECT create_time_partitions(
      table_name         := 'github_events',
      partition_interval := '1 month',
      end_at             := now() + '12 months'
  )
$$);

-- 2. (Optional) Ensure we never have more than one year of data

SELECT cron.schedule('drop-partitions', '0 0 1 * *', $$
  CALL drop_old_time_partitions(
      'github_events',
      now() - interval '12 months' /* older_than */
  );
$$);
```

> **Note**
>
> Be aware that native partitioning in Postgres Pro is still quite new and has a few quirks. Maintenance operations on partitioned tables will acquire aggressive locks that can briefly stall queries.

J.5.5.3.3. Archiving with Columnar Storage

Some applications have data that logically divides into a small updatable part and a larger part that is "frozen". Examples include logs, clickstreams, or sales records. In this case we can combine partitioning with columnar table storage to compress historical partitions on disk. citus columnar tables are currently append-only, meaning they do not support updates or deletes, but we can use them for the immutable historical partitions.

A partitioned table may be made up of any combination of row and columnar partitions. When using range partitioning on a timestamp key, we can make the newest partition a row table, and periodically roll the newest partition into another historical columnar partition.

Let's see an example, using GitHub events again. We will create a new table called `github_columnar_events` for disambiguation from the earlier example. To focus entirely on the columnar storage aspect, we will not distribute this table.

Next, download sample data:

```
wget http://examples.citusdata.com/github_archive/github_events-2015-01-01-
{0..5}.csv.gz
gzip -c -d github_events-2015-01-01-*.gz >> github_events.csv
```

```
-- Our new table, same structure as the example in
-- the previous section
```

```
CREATE TABLE github_columnar_events ( LIKE github_events )
PARTITION BY RANGE (created_at);

-- Create partitions to hold two hours of data each

SELECT create_time_partitions(
  table_name         := 'github_columnar_events',
  partition_interval := '2 hours',
  start_from         := '2015-01-01 00:00:00',
  end_at             := '2015-01-01 08:00:00'
);

-- Fill with sample data
-- (note that this data requires the database to have UTF8 encoding)

\COPY github_columnar_events FROM 'github_events.csv' WITH (format CSV)

-- List the partitions, and confirm they are
-- using row-based storage (heap access method)

SELECT partition, access_method
  FROM time_partitions
 WHERE parent_table = 'github_columnar_events'::regclass;
```

```
┌──────────────────────────────────────────┬───────────────┐
│                partition                 │ access_method │
├──────────────────────────────────────────┼───────────────┤
│ github_columnar_events_p2015_01_01_0000  │ heap          │
│ github_columnar_events_p2015_01_01_0200  │ heap          │
│ github_columnar_events_p2015_01_01_0400  │ heap          │
│ github_columnar_events_p2015_01_01_0600  │ heap          │
└──────────────────────────────────────────┴───────────────┘
```

```
-- Convert older partitions to use columnar storage

CALL alter_old_partitions_set_access_method(
  'github_columnar_events',
  '2015-01-01 06:00:00' /* older_than */,
  'columnar'
);

-- The old partitions are now columnar, while the
-- latest uses row storage and can be updated

SELECT partition, access_method
  FROM time_partitions
 WHERE parent_table = 'github_columnar_events'::regclass;
```

```
┌──────────────────────────────────────────┬───────────────┐
│                partition                 │ access_method │
├──────────────────────────────────────────┼───────────────┤
│ github_columnar_events_p2015_01_01_0000  │ columnar      │
│ github_columnar_events_p2015_01_01_0200  │ columnar      │
│ github_columnar_events_p2015_01_01_0400  │ columnar      │
│ github_columnar_events_p2015_01_01_0600  │ heap          │
└──────────────────────────────────────────┴───────────────┘
```

To see the compression ratio for a columnar table, use `VACUUM VERBOSE`. The compression ratio for our three columnar partitions is pretty good:

```
VACUUM VERBOSE github_columnar_events;
```

```
INFO:  statistics for "github_columnar_events_p2015_01_01_0000":
storage id: 10000000003
total file size: 4481024, total data size: 4444425
compression rate: 8.31x
total row count: 15129, stripe count: 1, average rows per stripe: 15129
chunk count: 18, containing data for dropped columns: 0, zstd compressed: 18

INFO:  statistics for "github_columnar_events_p2015_01_01_0200":
storage id: 10000000004
total file size: 3579904, total data size: 3548221
compression rate: 8.26x
total row count: 12714, stripe count: 1, average rows per stripe: 12714
chunk count: 18, containing data for dropped columns: 0, zstd compressed: 18

INFO:  statistics for "github_columnar_events_p2015_01_01_0400":
storage id: 10000000005
total file size: 2949120, total data size: 2917407
compression rate: 8.51x
total row count: 11756, stripe count: 1, average rows per stripe: 11756
chunk count: 18, containing data for dropped columns: 0, zstd compressed: 18
```

One power of the partitioned table `github_columnar_events` is that it can be queried in its entirety like a normal table.

```
SELECT COUNT(DISTINCT repo_id)
  FROM github_columnar_events;
```

```
┌─────────┐
│ count   │
├─────────┤
│ 16001   │
└─────────┘
```

Entries can be updated or deleted, as long as there is a `WHERE` clause on the partition key, which filters entirely into row table partitions.

Archiving a Row Partition to Columnar Storage

When a row partition has filled its range, you can archive it to compressed columnar storage. We can automate this with pg_cron like so:

```
-- A monthly cron job

SELECT cron.schedule('compress-partitions', '0 0 1 * *', $$
  CALL alter_old_partitions_set_access_method(
    'github_columnar_events',
    now() - interval '6 months' /* older_than */,
    'columnar'
  );
$$);
```

For more information, see the Columnar Storage section.

J.5.6. Architecture Concepts

J.5.6.1. Nodes

citus is a Postgres Pro extension that allows commodity database servers (called *nodes*) to coordinate with one another in a “shared-nothing” architecture. The nodes form a *cluster* that allows Postgres Pro to hold more data and use more CPU cores than would be possible on a single computer. This architecture also allows the database to scale by simply adding more nodes to the cluster.

Every cluster has one special node called the *coordinator* (the others are known as workers). Applications send their queries to the coordinator node, which relays it to the relevant workers and accumulates the results.

For each query, the coordinator either *routes* it to a single worker node, or *parallelizes* it across several depending on whether the required data lives on a single node or multiple. The coordinator knows how to do this by consulting its metadata tables. These tables specific to citus track the DNS names and health of worker nodes, and the distribution of data across nodes. For more information, see the citus Tables and Views section.

J.5.6.2. Sharding Models

Sharding is a technique used in database systems and distributed computing to horizontally partition data across multiple servers or nodes. It involves breaking up a large database or dataset into smaller, more manageable parts called shards. Each shard contains a subset of the data, and together they form the complete dataset.

citus offers two types of data sharding: row-based and schema-based. Each option comes with its own sharding tradeoffs allowing you to choose the approach that best aligns with requirements of your application.

J.5.6.2.1. Row-Based Sharding

The traditional way in which citus shards tables is the single database, shared schema model also known as row-based sharding, tenants co-exist as rows within the same table. The tenant is determined by defining the distribution column, which allows splitting up a table horizontally.

This is the most hardware efficient way of sharding. Tenants are densely packed and distributed among the nodes in the cluster. This approach, however, requires making sure that all tables in the schema have the distribution column and that all queries in the application filter by it. Row-based sharding shines in IoT workloads and for achieving the best margin out of hardware use.

Benefits:

- Best performance
- Best tenant density per node

Drawbacks:

- Requires schema modifications
- Requires application query modifications
- All tenants must share the same schema

J.5.6.2.2. Schema-Based Sharding

Schema-based sharding is the shared database, separate schema model, the schema becomes the logical shard within the database. Multi-tenant apps can a use a schema per tenant to easily shard along the tenant dimension. Query changes are not required and the application usually only needs a small modification to set the proper `search_path` when switching tenants. Schema-based sharding is an ideal solution for microservices, and for ISVs deploying applications that cannot undergo the changes required to onboard row-based sharding.

Benefits:

- Tenants can have heterogeneous schemas
- No schema modifications required
- No application query modifications required
- Schema-based sharding SQL compatibility is better compared to the row-based sharding

Drawbacks:

- Fewer tenants per node compared to row-based sharding

J.5.6.2.3. Sharding Tradeoffs

	Schema-Based Sharding	**Row-Based Sharding**
Multi-tenancy model	Separate schema per tenant	Shared tables with tenant ID columns
citus version	12.0+	All versions
Additional steps compared to Postgres Pro	None, only a config change	Use the create_distributed_table function on each table to distribute and co-locate tables by `tenant_id`
Number of tenants	1-10k	1-1M+
Data modelling requirement	No foreign keys across distributed schemas	Need to include the `tenant_id` column (a distribution column, also known as a sharding key) in each table, and in primary keys, foreign keys
SQL requirement for single node queries	Use a single distributed schema per query	Joins and `WHERE` clauses should include `tenant_id` column
Parallel cross-tenant queries	No	Yes
Custom table definitions per tenant	Yes	No
Access control	Schema permissions	Schema permissions
Data sharing across tenants	Yes, using reference tables (in a separate schema)	Yes, using reference tables
Tenant to shard isolation	Every tenant has its own shard group by definition	Can give specific tenant IDs their own shard group via the isolate_tenant_to_new_shard function.

J.5.6.3. Distributed Data

J.5.6.3.1. Table Types

There are several types of tables in a citus cluster, each used for different purposes.

- Type 1: Distributed Tables.

  The first type, and most common, is *distributed* tables. These appear to be normal tables to SQL statements, but are horizontally *partitioned* across worker nodes. See the figure below to learn more.

  Figure J.8. Parallel `SELECT` Diagram

  
  Here the rows of `table` are stored in tables `table_1001`, `table_1002`, etc. on the workers. The component worker tables are called *shards*.

citus runs not only SQL but DDL statements throughout a cluster, so changing the schema of a distributed table cascades to update all the table shards across workers.

To learn how to create a distributed table, see the Creating and Modifying Distributed Objects (DDL) section.

Distribution Column. citus uses algorithmic sharding to assign rows to shards. This means the assignment is made deterministically — in our case based on the value of a particular table column called the *distribution column*. The cluster administrator must designate this column when distributing a table. Making the right choice is important for performance and functionality, as described in the general topic of the Choosing Distribution Column section.

- Type 2: Reference Tables.

  A reference table is a type of distributed table whose entire contents are concentrated into a single shard, which is replicated on every worker. Thus queries on any worker can access the reference information locally, without the network overhead of requesting rows from another node. Reference tables have no distribution column because there is no need to distinguish separate shards per row.

  Reference tables are typically small and are used to store data that is relevant to queries running on any worker node. For example, enumerated values like order statuses or product categories.

  When interacting with a reference table, we automatically perform two-phase commits on transactions. This means that citus makes sure your data is always in a consistent state, regardless of whether you are writing, modifying or deleting it.

  The Reference Tables section talks more about these tables and how to create them.

- Type 3: Local Tables.

  When you use citus, the coordinator node you connect to and interact with is a regular Postgres Pro database with the citus extension installed. Thus you can create ordinary tables and choose not to shard them. This is useful for small administrative tables that do not participate in join queries. An example would be users table for application login and authentication.

  Creating standard Postgres Pro tables is easy because it is the default. It is what you get when you run `CREATE TABLE`. In almost every citus deployment we see standard Postgres Pro tables co-existing with distributed and reference tables. Indeed, citus itself uses local tables to hold cluster metadata, as mentioned earlier.

- Type 4: Local Managed Tables.

  When the citus.enable_local_reference_table_foreign_keys configuration parameter is enabled, citus may automatically add local tables to metadata if a foreign key reference exists between a local table and a reference table. Additionally this tables can be manually created by calling the citus_add_local_table_to_metadata function on regular local tables. Tables present in metadata are considered managed tables and can be queried from any node, citus will know to route to the coordinator to obtain data from the local managed table. Such tables are displayed as local in the citus_tables view.

- Type 5: Schema Tables.

  When using schema-based sharding, distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas are automatically converted to co-located distributed tables without a shard key. Such tables are considered schema tables and are displayed as schema in the citus_tables view.

J.5.6.3.2. Shards

The previous section described a shard as containing a subset of the rows of a distributed table in a smaller table within a worker node. This section gets more into the technical details.

The pg_dist_shard metadata table on the coordinator contains a row for each shard of each distributed table in the system. The row matches a `shardid` with a range of integers in a hash space (`shardminvalue`, `shardmaxvalue`):

```
SELECT * FROM pg_dist_shard;
 logicalrelid  | shardid | shardstorage | shardminvalue | shardmaxvalue
---------------+---------+--------------+---------------+---------------
 github_events |  102026 | t            | 268435456     | 402653183
 github_events |  102027 | t            | 402653184     | 536870911
 github_events |  102028 | t            | 536870912     | 671088639
 github_events |  102029 | t            | 671088640     | 805306367
 (4 rows)
```

If the coordinator node wants to determine which shard holds a row of `github_events`, it hashes the value of the distribution column in the row, and checks which shard's range contains the hashed value. (The ranges are defined so that the image of the hash function is their disjoint union.)

J.5.6.3.2.1. Shard Placements

Suppose that shard `102027` is associated with the row in question. This means the row should be read or written to a table called `github_events_102027` in one of the workers. Which worker? That is determined entirely by the metadata tables, and the mapping of shard to worker is known as the shard *placement*.

Joining some metadata tables gives us the answer. These are the types of lookups that the coordinator does to route queries. It rewrites queries into fragments that refer to the specific tables like `github_events_102027`, and runs those fragments on the appropriate workers.

```
SELECT
    shardid,
    node.nodename,
    node.nodeport
FROM pg_dist_placement placement
JOIN pg_dist_node node
  ON placement.groupid = node.groupid
 AND node.noderole = 'primary'::noderole
WHERE shardid = 102027;
```

```
┌─────────┬──────────┬──────────┐
│ shardid │ nodename │ nodeport │
├─────────┼──────────┼──────────┤
│  102027 │ localhost│     5433 │
└─────────┴──────────┴──────────┘
```

In our example of `github_events` there were four shards. The number of shards is configurable per table at the time of its distribution across the cluster. The best choice of shard count depends on your use case, see the Shard Count section.

Finally note that citus allows shards to be replicated for protection against data loss using Postgres Pro streaming replication to back up the entire database of each node to a follower database. This is transparent and does not require the involvement of citus metadata tables.

J.5.6.3.3. Co-Location

Since shards can be placed on nodes as desired, it makes sense to place shards containing related rows of related tables together on the same nodes. That way join queries between them can avoid sending as much information over the network, and can be performed inside a single citus node.

One example is a database with stores, products, and purchases. If all three tables contain — and are distributed by — the `store_id` column, then all queries restricted to a single store can run efficiently on a single worker node. This is true even when the queries involve any combination of these tables.

For the full explanation and examples of this concept, see the Table Co-Location section.

J.5.6.3.4. Parallelism

Spreading queries across multiple computers allows more queries to run at once, and allows processing speed to scale by adding new computers to the cluster. Additionally splitting a single query into fragments as described in the previous section boosts the processing power devoted to it. The latter situation achieves the greatest *parallelism*, meaning utilization of CPU cores.

Queries reading or affecting shards spread evenly across many nodes are able to run at "real-time" speed. Note that the results of the query still need to pass back through the coordinator node, so the speedup is most apparent when the final results are compact, such as aggregate functions like counting and descriptive statistics.

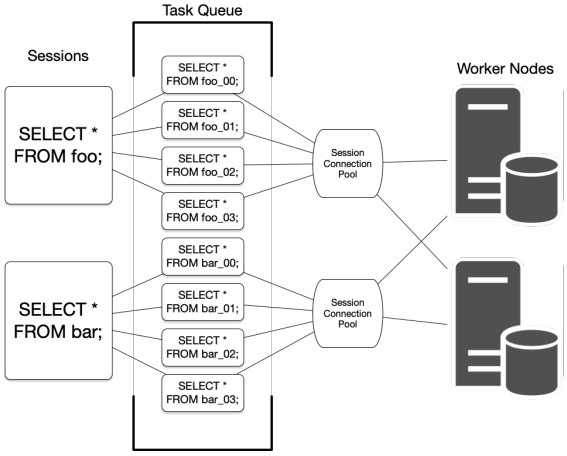
The Query Processing section explains more about how queries are broken into fragments and how their execution is managed.

J.5.6.4. Query Execution

When executing multi-shard queries, citus must balance the gains from parallelism with the overhead from database connections (network latency and worker node resource usage). To configure citus query execution for best results with your database workload, it helps to understand how citus manages and conserves database connections between the coordinator node and worker nodes.

citus transforms each incoming multi-shard query session into per-shard queries called tasks. It queues the tasks, and runs them once it is able to obtain connections to the relevant worker nodes. For queries on distributed tables `foo` and `bar`, see the connection management diagram below.

Figure J.9. Executor Overview



The coordinator node has a connection pool for each session. Each query (such as `SELECT * FROM foo` in the diagram) is limited to opening at most simultaneous connections for its tasks per worker set in the citus.max_adaptive_executor_pool_size configuration parameter. It is configurable at the session level, for priority management.

It can be faster to execute short tasks sequentially over the same connection rather than establishing new connections for them in parallel. Long running tasks, on the other hand, benefit from more immediate parallelism.

To balance the needs of short and long tasks, citus uses the citus.executor_slow_start_interval configuration parameter. It specifies a delay between connection attempts for the tasks in a multi-shard query. When a query first queues tasks, the tasks can acquire just one connection. At the end of each interval where there are pending connections, citus increases the number of simultaneous connections it will open. The slow start behavior can be disabled entirely by setting the GUC to `0`.

When a task finishes using a connection, the session pool will hold the connection open for later. Caching the connection avoids the overhead of connection reestablishment between coordinator and worker.

However, each pool will hold no more than the number of idle connections open at once set by the citus.max_cached_conns_per_worker configuration parameter, to limit idle connection resource usage in the worker.

Finally, the citus.max_shared_pool_size configuration parameter acts as a fail-safe. It limits the total connections per worker between all tasks.

For recommendations about tuning these parameters to match your workload, see the Connection Management section.

J.5.7. Develop

J.5.7.1. Determining Application Type

Running efficient queries on a citus cluster requires that data be properly distributed across computers. This varies by the type of application and its query patterns.

There are broadly two kinds of applications that work very well on citus. The first step in data modeling is to identify which of them more closely resembles your application.

J.5.7.1.1. At a Glance

Multi-Tenant Applications	Real-Time Applications
Sometimes dozens or hundreds of tables in schema	Small number of tables
Queries relating to one tenant (company/store) at a time	Relatively simple analytics queries with aggregations
OLTP workloads for serving web clients	High ingest volume of mostly immutable data
OLAP workloads that serve per-tenant analytical queries	Often centering around a big table of events

J.5.7.1.2. Examples and Characteristics

J.5.7.1.2.1. Multi-Tenant Applications

These are typically SaaS applications that serve other companies, accounts, or organizations. Most SaaS applications are inherently relational. They have a natural dimension on which to distribute data across nodes: just shard by `tenant_id`.

citus enables you to scale out your database to millions of tenants without having to re-architect your application. You can keep the relational semantics you need, like joins, foreign key constraints, transactions, ACID, and consistency.

- **Examples**: Websites, which host store-fronts for other businesses, such as a digital marketing solution, or a sales automation tool.
- **Characteristics**: Queries relating to a single tenant rather than joining information across tenants. This includes OLTP workloads for serving web clients, and OLAP workloads that serve per-tenant analytical queries. Having dozens or hundreds of tables in your database schema is also an indicator for the multi-tenant data model.

Scaling a multi-tenant app with citus also requires minimal changes to application code. We have support for popular frameworks like Ruby on Rails and Django.

J.5.7.1.2.2. Real-Time Analytics

Applications needing massive parallelism, coordinating hundreds of cores for fast results to numerical, statistical, or counting queries. By sharding and parallelizing SQL queries across multiple nodes, citus makes it possible to perform real-time queries across billions of records in under a second.

- **Examples**: Customer-facing analytics dashboards requiring sub-second response times.

- **Characteristics**: Few tables, often centering around a big table of device-, site- or user-events and requiring high ingest volume of mostly immutable data. Relatively simple (but computationally intensive) analytics queries involving several aggregations and `GROUP BY` operations.

If your situation resembles either cases above, then the next step is to decide how to shard your data in the citus cluster. As explained in the Architecture Concepts section, citus assigns table rows to shards according to the hashed value of the table distribution column. The database administrator's choice of distribution columns needs to match the access patterns of typical queries to ensure performance.

J.5.7.2. Choosing Distribution Column

citus uses the distribution column in distributed tables to assign table rows to shards. Choosing the distribution column for each table is **one of the most important** modeling decisions because it determines how data is spread across nodes.

If the distribution columns are chosen correctly, then related data will group together on the same physical nodes, making queries fast and adding support for all SQL features. If the columns are chosen incorrectly, the system will run needlessly slowly, and will not be able to support all SQL features across nodes.

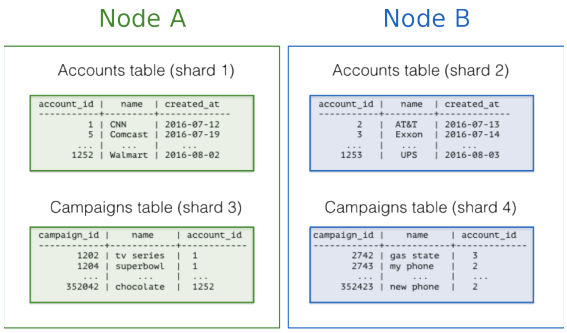
This section gives distribution column tips for the two most common citus scenarios. It concludes by going in-depth on “co-location”, the desirable grouping of data on nodes.

J.5.7.2.1. Multi-Tenant Apps

The multi-tenant architecture uses a form of hierarchical database modeling to distribute queries across nodes in the distributed cluster. The top of the data hierarchy is known as the `tenant_id`, and needs to be stored in a column on each table. citus inspects queries to see which `tenant_id` they involve and routes the query to a single worker node for processing, specifically the node that holds the data shard associated with the `tenant_id`. Running a query with all relevant data placed on the same node is called co-location.

The following diagram illustrates co-location in the multi-tenant data model. It contains two tables, Accounts and Campaigns, each distributed by `account_id`. The shaded boxes represent shards, each of whose color represents which worker node contains it. Green shards are stored together on one worker node, and blue on another. Notice how a join query between Accounts and Campaigns would have all the necessary data together on one node when restricting both tables to the same `account_id`.

Figure J.10. Multi-Tenant Co-Location



To apply this design in your own schema the first step is identifying what constitutes a tenant in your application. Common instances include company, account, organization, or customer. The column name will be something like `company_id` or `customer_id`. Examine each of your queries and ask yourself: would it work if it had additional `WHERE` clauses to restrict all tables involved to rows with the same `tenant_id`? Queries in the multi-tenant model are usually scoped to a tenant, for instance, queries on sales or inventory would be scoped within a certain store.

Best practices are as follows:

- **Partition distributed tables by the common** `tenant_id` **column**. For instance, in a SaaS application where tenants are companies, the `tenant_id` will likely be `company_id`.
- **Convert small cross-tenant tables to reference tables**. When multiple tenants share a small table of information, distribute it as a reference table.
- **Restrict filter all application queries by** `tenant_id`. Each query should request information for one tenant at a time.

Consult the Multi-Tenant Applications section for a detailed example of building this kind of application.

J.5.7.2.2. Real-Time Apps

While the multi-tenant architecture introduces a hierarchical structure and uses data co-location to route queries per tenant, real-time architectures depend on specific distribution properties of their data to achieve highly parallel processing.

We use “entity ID” as a term for distribution columns in the real-time model, as opposed to tenant IDs in the multi-tenant model. Typical entities are users, hosts, or devices.

Real-time queries typically ask for numeric aggregates grouped by date or category. citus sends these queries to each shard for partial results and assembles the final answer on the coordinator node. Queries run fastest when as many nodes contribute as possible, and when no single node must do a disproportionate amount of work.

Best practices are as follows:

- **Choose a column with high cardinality as the distribution column**. For comparison, a “status” field on an order table with values “new”, “paid”, and “shipped” is a poor choice of distribution column because it assumes only those few values. The number of distinct values limits the number of shards that can hold the data, and the number of nodes that can process it. Among columns with high cardinality, it is good additionally to choose those that are frequently used in group-by clauses or as join keys.
- **Choose a column with even distribution**. If you distribute a table on a column skewed to certain common values, then data in the table will tend to accumulate in certain shards. The nodes holding those shards will end up doing more work than other nodes.
- **Distribute fact and dimension tables on their common columns**. Your fact table can have only one distribution key. Tables that join on another key will not be co-located with the fact table. Choose one dimension to co-locate based on how frequently it is joined and the size of the joining rows.
- **Change some dimension tables into reference tables**. If a dimension table cannot be co-located with the fact table, you can improve query performance by distributing copies of the dimension table to all of the nodes in the form of a reference table.

Consult the Real-Time Dashboards section for a detailed example of building this kind of application.

J.5.7.2.3. Timeseries Data

In a time-series workload, applications query recent information while archiving old information.

The most common mistake in modeling timeseries information in citus is using the timestamp itself as a distribution column. A hash distribution based on time will distribute times seemingly at random into different shards rather than keeping ranges of time together in shards. However, queries involving time generally reference ranges of time (for example, the most recent data), so such a hash distribution would lead to network overhead.

Best practices are as follows:

- **Do not choose a timestamp as the distribution column**. Choose a different distribution column. In a multi-tenant app, use the `tenant_id` or in a real-time app use the `entity_id`.

- **Use Postgres Pro table partitioning for time instead**. Use table partitioning to break a big table of time-ordered data into multiple inherited tables with each containing different time ranges. Distributing a Postgres Pro partitioned table in citus creates shards for the inherited tables.

Consult the Timeseries Data section for a detailed example of building this kind of application.

J.5.7.2.4. Table Co-Location

Relational databases are the first choice of data store for many applications due to their enormous flexibility and reliability. Historically the one criticism of relational databases is that they can run on only a single computer, which creates inherent limitations when data storage needs outpace server improvements. The solution to rapidly scaling databases is to distribute them, but this creates a performance problem of its own: relational operations such as joins then need to cross the network boundary. Co-location is the practice of dividing data tactically, where one keeps related information on the same computers to enable efficient relational operations, but takes advantage of the horizontal scalability for the whole dataset.

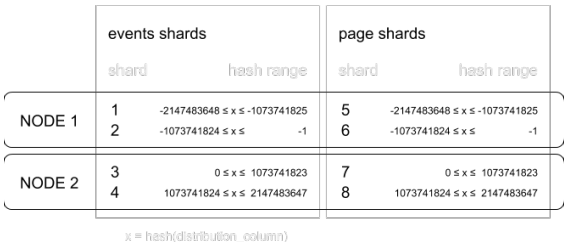
The principle of data co-location is that all tables in the database have a common distribution column and are sharded across computers in the same way, such that rows with the same distribution column value are always on the same computer, even across different tables. As long as the distribution column provides a meaningful grouping of data, relational operations can be performed within the groups.

J.5.7.2.4.1. Data Co-Location in citus for Hash-Distributed Tables

The citus extension for Postgres Pro is unique in being able to form a distributed database of databases. Every node in a citus cluster is a fully functional Postgres Pro database and the extension adds the experience of a single homogenous database on top. While it does not provide the full functionality of Postgres Pro in a distributed way, in many cases it can take full advantage of features offered by Postgres Pro on a single computer through co-location, including full SQL support, transactions, and foreign keys.

In citus a row is stored in a shard if the hash of the value in the distribution column falls within the shard hash range. To ensure co-location, shards with the same hash range are always placed on the same node even after rebalance operations, such that equal distribution column values are always on the same node across tables. See the figure below to learn more.

Figure J.11. Co-Location Shards



A distribution column that we have found to work well in practice is `tenant_id` in multi-tenant applications. For example, SaaS applications typically have many tenants, but every query they make is specific to a particular tenant. While one option is providing a database or schema for every tenant, it is often costly and impractical as there can be many operations that span across users (data loading, migrations, aggregations, analytics, schema changes, backups, etc). That becomes harder to manage as the number of tenants grows.

J.5.7.2.4.2. Practical Example of Co-Location

Consider the following tables, which might be part of a multi-tenant web analytics SaaS:

```
CREATE TABLE event (
  tenant_id int,
  event_id bigint,
  page_id int,
  payload jsonb,
```

```
  primary key (tenant_id, event_id)
);

CREATE TABLE page (
  tenant_id int,
  page_id int,
  path text,
  primary key (tenant_id, page_id)
);
```

Now we want to answer queries that may be issued by a customer-facing dashboard, such as: “Return the number of visits in the past week for all pages starting with `/blog` in tenant six”.

J.5.7.2.4.3. Using Regular Postgres Pro Tables

If our data was in a single Postgres Pro node, we could easily express our query using the rich set of relational operations offered by SQL:

```
SELECT page_id, count(event_id)
FROM
  page
LEFT JOIN  (
  SELECT * FROM event
  WHERE (payload->>'time')::timestamptz >= now() - interval '1 week'
) recent
USING (tenant_id, page_id)
WHERE tenant_id = 6 AND path LIKE '/blog%'
GROUP BY page_id;
```

As long as the *working set* for this query fits in memory, this is an appropriate solution for many applications since it offers maximum flexibility. However, even if you do not need to scale yet, it can be useful to consider the implications of scaling out on your data model.

J.5.7.2.4.4. Distributing Tables by ID

As the number of tenants and the data stored for each tenant grows, query times will typically go up as the working set no longer fits in memory or CPU becomes a bottleneck. In this case, we can shard the data across many nodes using citus. The first and the most important choice we need to make when sharding is the distribution column. Let's start with a naive choice of using `event_id` for the `event` table and `page_id` for the `page` table:

```
-- Naively use event_id and page_id as distribution columns

SELECT create_distributed_table('event', 'event_id');
SELECT create_distributed_table('page', 'page_id');
```

Given that the data is dispersed across different workers, we cannot simply perform a join as we would on a single Postgres Pro node. Instead, we will need to issue two queries:

Across all shards of the page table (Q1):

```
SELECT page_id FROM page WHERE path LIKE '/blog%' AND tenant_id = 6;
```

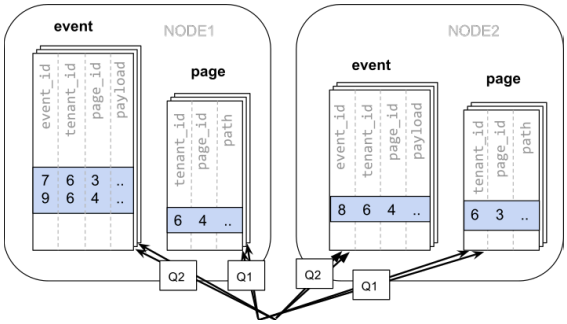
Across all shards of the event table (Q2):

```
SELECT page_id, count(*) AS count
FROM event
WHERE page_id IN (/*…page IDs from first query…*/)
  AND tenant_id = 6
  AND (payload->>'time')::date >= now() - interval '1 week'
GROUP BY page_id ORDER BY count DESC LIMIT 10;
```

Afterwards, the results from the two steps need to be combined by the application.

The data required to answer the query is scattered across the shards on the different nodes and each of those shards will need to be queried. See the figure below to learn more.

Figure J.12. Co-Location With Inefficient Queries



In this case the data distribution creates substantial drawbacks:

- Overhead from querying each shard, running multiple queries.
- Overhead of Q1 returning many rows to the client.
- Q2 becomes very large.
- The need to write queries in multiple steps, combine results, requires changes in the application.

A potential upside of the relevant data being dispersed is that the queries can be parallelised, which citus will do. However, this is only beneficial if the amount of work that the query does is substantially greater than the overhead of querying many shards. It is generally better to avoid doing such heavy lifting directly from the application, for example, by pre-aggregating the data.

J.5.7.2.4.5. Distributing Tables by Tenant

Looking at our query again, we can see that all the rows that the query needs have one dimension in common: `tenant_id`. The dashboard will only ever query for a tenant's own data. That means that if data for the same tenant is always co-located on a single Postgres Pro node, our original query could be answered in a single step by that node by performing a join on `tenant_id` and `page_id`.

In citus, rows with the same distribution column value are guaranteed to be on the same node. Each shard in a distributed table effectively has a set of co-located shards from other distributed tables that contain the same distribution column values (data for the same tenant). Starting over, we can create our tables with `tenant_id` as the distribution column.

```
-- Co-locate tables by using a common distribution column
SELECT create_distributed_table('event', 'tenant_id');
SELECT create_distributed_table('page', 'tenant_id', colocate_with => 'event');
```

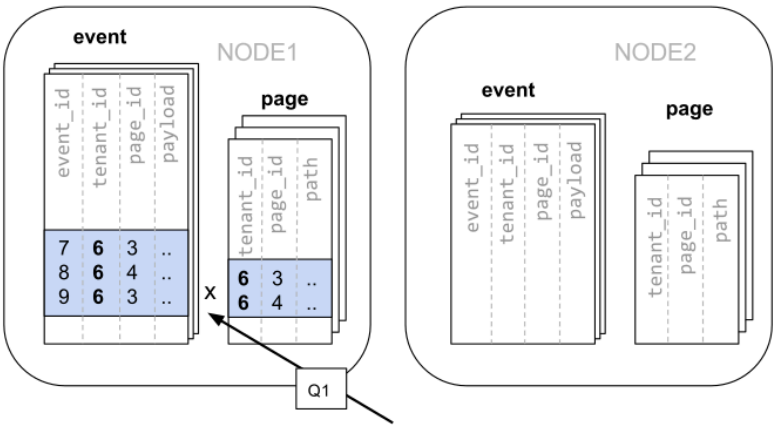
In this case, citus can answer the same query that you would run on a single Postgres Pro node without modification (Q1):

```
SELECT page_id, count(event_id)
FROM
  page
LEFT JOIN  (
  SELECT * FROM event
  WHERE (payload->>'time')::timestamptz >= now() - interval '1 week'
) recent
USING (tenant_id, page_id)
WHERE tenant_id = 6 AND path LIKE '/blog%'
GROUP BY page_id;
```

Because of the `tenant_id` filter and join on `tenant_id`, citus knows that the entire query can be answered using the set of co-located shards that contain the data for that particular tenant, and the Postgres Pro

node can answer the query in a single step, which enables full SQL support. See the figure below to learn more.

Figure J.13. Co-Location With Better Queries



In some cases, queries and table schemas will require minor modifications to ensure that the `tenant_id` is always included in unique constraints and join conditions. However, this is usually a straightforward change, and the extensive rewrite that would be required without having co-location is avoided.

While the example above queries just one node because there is a specific `tenant_id = 6` filter, co-location also allows us to efficiently perform distributed joins on `tenant_id` across all nodes, be it with SQL limitations.

J.5.7.2.4.6. Co-Location Means Better Feature Support

The full list of citus features that are unlocked by co-location are:

- Full SQL support for queries on a single set of co-located shards.
- Multi-statement transaction support for modifications on a single set of co-located shards.
- Aggregation through `INSERT...SELECT`.
- Foreign keys.
- Distributed outer joins.
- Pushdown CTEs.

Data co-location is a powerful technique for providing both horizontal scale and support to relational data models. The cost of migrating or building applications using a distributed database that enables relational operations through co-location is often substantially lower than moving to a restrictive data model (e.g. NoSQL) and, unlike a single-node database, it can scale out with the size of your business. For more information about migrating an existing database, see the Migrating an Existing App.

J.5.7.2.4.7. Query Performance

citus parallelizes incoming queries by breaking it into multiple fragment queries (“tasks”), which run on the worker shards in parallel. This allows citus to utilize the processing power of all the nodes in the cluster and also of individual cores on each node for each query. Due to this parallelization, you can get performance, which is cumulative of the computing power of all of the cores in the cluster leading to a dramatic decrease in query times versus Postgres Pro on a single server.

citus employs a two stage optimizer when planning SQL queries. The first phase involves converting the SQL queries into their commutative and associative form so that they can be pushed down and run on the workers in parallel. As discussed in previous sections, choosing the right distribution column and distribution method allows the distributed query planner to apply several optimizations to the queries. This can have a significant impact on query performance due to reduced network I/O.

The distributed executor of the citus extension then takes these individual query fragments and sends them to worker Postgres Pro instances. There are several aspects of both the distributed planner and the executor, which can be tuned in order to improve performance. When these individual query fragments are sent to the workers, the second phase of query optimization kicks in. The workers are simply running extended Postgres Pro servers and they apply Postgres Pro standard planning and execution logic to run these fragment SQL queries. Therefore, any optimization that helps Postgres Pro also helps citus. Postgres Pro by default comes with conservative resource settings; and therefore optimizing these configuration settings can improve query times significantly.

We discuss the relevant performance tuning steps in the Query Performance Tuning section.

J.5.7.3. Migrating an Existing App

Migrating an existing application to citus sometimes requires adjusting the schema and queries for optimal performance. citus extends Postgres Pro with distributed functionality, but row-based sharding is not a drop-in replacement that scales out all workloads. A performant citus cluster involves thinking about the data model, tooling, and choice of SQL features used.

There is another mode of operation in citus called schema-based sharding, and while row-based sharding results in best performance and hardware efficiency, see schema-based sharding if you are in a need for a more drop-in approach.

1. The first steps are to optimize the existing database schema so that it can work efficiently across multiple computers.
   a. Identify Distribution Strategy
      i. Pick Distribution Key
      ii. Identify Types of Tables
   b. Prepare Source Tables for Migration
      i. Add Distribution Keys
      ii. Backfill Newly Created Columns
2. Next, update application code and queries to deal with the schema changes.
   a. Prepare Application for citus
      i. Set Up Development citus Cluster
      ii. Add Distribution Key to Queries
      iii. Enable Secure Connections
      iv. Check for Cross-Node Traffic
3. After testing the changes in a development environment, the last step is to migrate production data to a citus cluster and switch over the production app. We have techniques to minimize downtime for this step.
   a. Migrate Production Data
      i. Database Migration

J.5.7.3.1. Identify Distribution Strategy

J.5.7.3.1.1. Pick Distribution Key

The first step in migrating to citus is identifying suitable distribution keys and planning table distribution accordingly. In multi-tenant applications this will typically be an internal identifier for tenants. We typically refer to it as the `tenant_id`. The use cases may vary, so we advise being thorough on this step.

For guidance, consult these sections:

1. Determining Application Type

2. Choosing Distribution Column

Review your environment to be sure that the ideal distribution key is chosen. To do so, examine schema layouts, larger tables, long-running and/or problematic queries, standard use cases, and more.

J.5.7.3.1.2. Identify Types of Tables

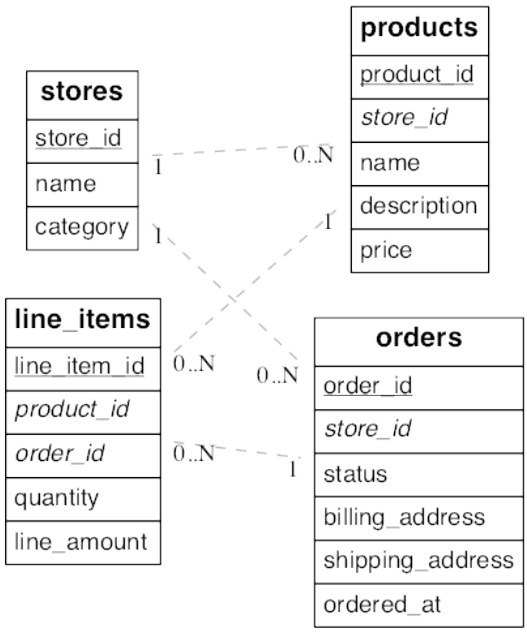
Once a distribution key is identified, review the schema to identify how each table will be handled and whether any modifications to table layouts will be required.

Tables will generally fall into one of the following categories:

- Ready for distribution. These tables already contain the distribution key, and are ready for distribution.
- Needs backfill. These tables can be logically distributed by the chosen key but do not contain a column directly referencing it. The tables will be modified later to add the column.
- Reference table. These tables are typically small, do not contain the distribution key, are commonly joined by distributed tables, and/or are shared across tenants. A copy of each of these tables will be maintained on all nodes. Common examples include country code lookups, product categories, and the like.
- Local table. These are typically not joined to other tables, and do not contain the distribution key. They are maintained exclusively on the coordinator node. Common examples include admin user lookups and other utility tables.

Consider an example multi-tenant application similar to Etsy or Shopify where each tenant is a store. A simplified schema is presented in the diagram below. (Underlined items are primary keys, italicized items are foreign keys.)

Figure J.14. Simplified Schema Example



In this example stores are a natural tenant. The `tenant_id` is in this case the `store_id`. After distributing tables in the cluster, we want rows relating to the same store to reside together on the same nodes.

J.5.7.3.2. Prepare Source Tables for Migration

Once the scope of needed database changes is identified, the next major step is to modify the data structure for the application's existing database. First, tables requiring backfill are modified to add a column for the distribution key.

J.5.7.3.2.1. Add Distribution Keys

In our storefront example the stores and products tables have a `store_id` and are ready for distribution. Being normalized, the `line_items` table lacks `store_id`. If we want to distribute by `store_id`, the table needs this column.

```
-- Denormalize line_items by including store_id

ALTER TABLE line_items ADD COLUMN store_id uuid;
```

Be sure to check that the distribution column has the same type in all tables, e.g. do not mix `int` and `bigint`. The column types must match to ensure proper data co-location.

J.5.7.3.2.2. Backfill Newly Created Columns

Once the schema is updated, backfill missing values for the `tenant_id` column in tables where the column was added. In our example `line_items` requires values for `store_id`.

We backfill the table by obtaining the missing values from a join query with orders:

```
UPDATE line_items
   SET store_id = orders.store_id
  FROM line_items
 INNER JOIN orders
 WHERE line_items.order_id = orders.order_id;
```

Doing the whole table at once may cause too much load on the database and disrupt other queries. The backfill can be done more slowly instead. One way to do that is to make a function that backfills small batches at a time, then call the function repeatedly with *pg_cron*.

```
-- The function to backfill up to one
-- thousand rows from line_items

CREATE FUNCTION backfill_batch()
RETURNS void LANGUAGE sql AS $$
  WITH batch AS (
    SELECT line_items_id, order_id
      FROM line_items
     WHERE store_id IS NULL
     LIMIT 1000
       FOR UPDATE
      SKIP LOCKED
  )
  UPDATE line_items AS li
     SET store_id = orders.store_id
    FROM batch, orders
   WHERE batch.line_item_id = li.line_item_id
     AND batch.order_id = orders.order_id;
$$;

-- Run the function every quarter hour
SELECT cron.schedule('*/15 * * * *', 'SELECT backfill_batch()');

-- Note the return value of cron.schedule
```

Once the backfill is caught up, the cron job can be disabled:

```
-- Assuming 42 is the job id returned
-- from cron.schedule

SELECT cron.unschedule(42);
```

J.5.7.3.3. Prepare Application for citus

J.5.7.3.3.1. Set Up Development citus Cluster

When modifying the application to work with citus, you will need a database to test against. Follow the instructions in the Installing citus on a Single Node section to set up the extension.

Next dump a copy of the schema from your application's original database and restore the schema in the new development database.

```
# get schema from source db

pg_dump \
   --format=plain \
   --no-owner \
   --schema-only \
   --file=schema.sql \
   --schema=target_schema \
   postgres://user:pass@host:5432/db

# load schema into test db

psql postgres://user:pass@testhost:5432/db -f schema.sql
```

The schema should include a distribution key (`tenant_id`) in all tables you wish to distribute. Before running pg_dump for the schema, be sure to prepare source tables for migration.

Include Distribution Column in Keys

citus cannot enforce uniqueness constraints unless a unique index or primary key contains the distribution column. Thus we must modify primary and foreign keys in our example to include `store_id`.

Some of the libraries listed in the next section are able to help migrate the database schema to include the distribution column in keys. However, here is an example of the underlying SQL commands to turn the simple keys composite in the development database:

```
BEGIN;

-- Drop simple primary keys (cascades to foreign keys)

ALTER TABLE products   DROP CONSTRAINT products_pkey CASCADE;
ALTER TABLE orders     DROP CONSTRAINT orders_pkey CASCADE;
ALTER TABLE line_items DROP CONSTRAINT line_items_pkey CASCADE;

-- Recreate primary keys to include would-be distribution column

ALTER TABLE products   ADD PRIMARY KEY (store_id, product_id);
ALTER TABLE orders     ADD PRIMARY KEY (store_id, order_id);
ALTER TABLE line_items ADD PRIMARY KEY (store_id, line_item_id);

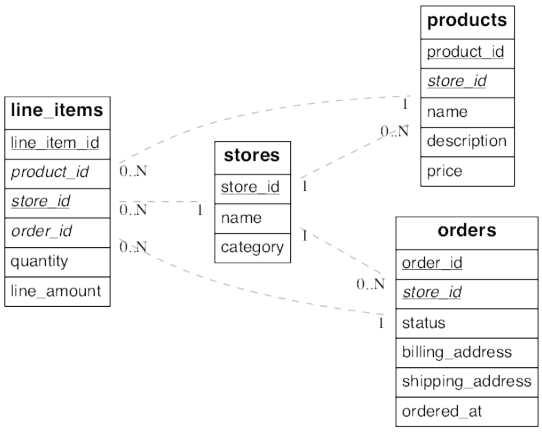
-- Recreate foreign keys to include would-be distribution column

ALTER TABLE line_items ADD CONSTRAINT line_items_store_fkey
  FOREIGN KEY (store_id) REFERENCES stores (store_id);
ALTER TABLE line_items ADD CONSTRAINT line_items_product_fkey
  FOREIGN KEY (store_id, product_id) REFERENCES products (store_id, product_id);
ALTER TABLE line_items ADD CONSTRAINT line_items_order_fkey
  FOREIGN KEY (store_id, order_id) REFERENCES orders (store_id, order_id);

COMMIT;
```

Thus completed, our schema from the previous section will look like this (Underlined items are primary keys, italicized items are foreign keys.):

Figure J.15. Simplified Schema Example



Be sure to modify data flows to add keys to incoming data.

J.5.7.3.3.2. Add Distribution Key to Queries

Once the distribution key is present on all appropriate tables, the application needs to include it in queries. Take the following steps using a copy of the application running in a development environment, and testing against a citus back-end. After the application is working with the extension we will see how to migrate production data from the source database into a real citus cluster.

- Application code and any other ingestion processes that write to the tables should be updated to include the new columns.
- Running the application test suite against the modified schema on citus is a good way to determine which areas of the code need to be modified.
- It is a good idea to enable database logging. The logs can help uncover stray cross-shard queries in a multi-tenant app that should be converted to per-tenant queries.

Cross-shard queries are supported, but in a multi-tenant application most queries should be targeted to a single node. For simple `SELECT`, `UPDATE`, and `DELETE` queries this means that the `WHERE` clause should filter by `tenant_id`. citus can then run these queries efficiently on a single node.

There are helper libraries for a number of popular application frameworks that make it easy to include `tenant_id` in queries:

- *Ruby on Rails*
- *Django Multitenant*
- *ASP.NET*
- *Java Hibernate*

It is possible to use the libraries for database writes first (including data ingestion) and later for read queries. The *activerecord-multi-tenant* gem, for instance, has a *write-only mode* that modifies only the write queries.

Other (SQL Principles)

If you are using a different ORM than those above or executing multi-tenant queries more directly in SQL, follow these general principles. We will use our earlier example of the e-commerce application.

Suppose we want to get the details for an order. Distributed queries that filter on the `tenant_id` run most efficiently in multi-tenant apps, so the change below makes the query faster (while both queries return the same results):

```
-- Before
SELECT *
  FROM orders
 WHERE order_id = 123;

-- After
SELECT *
  FROM orders
 WHERE order_id = 123
   AND store_id = 42; -- <== added
```

The `tenant_id` column is not just beneficial but critical for `INSERT` statements. Inserts must include a value for the `tenant_id` column or else citus will be unable to route the data to the correct shard and will raise an error.

Finally, when joining tables make sure to filter by `tenant_id` too. For instance, here is how to inspect how many “awesome wool pants” a given store has sold:

```
-- One way is to include store_id in the join and also
-- filter by it in one of the queries

SELECT sum(l.quantity)
  FROM line_items l
 INNER JOIN products p
    ON l.product_id = p.product_id
   AND l.store_id = p.store_id
 WHERE p.name='Awesome Wool Pants'
   AND l.store_id='8c69aa0d-3f13-4440-86ca-443566c1fc75'

-- Equivalently you omit store_id from the join condition
-- but filter both tables by it. This may be useful if
-- building the query in an ORM

SELECT sum(l.quantity)
  FROM line_items l
 INNER JOIN products p ON l.product_id = p.product_id
 WHERE p.name='Awesome Wool Pants'
   AND l.store_id='8c69aa0d-3f13-4440-86ca-443566c1fc75'
   AND p.store_id='8c69aa0d-3f13-4440-86ca-443566c1fc75'
```

J.5.7.3.3.3. Enable Secure Connections

Clients should connect to citus with SSL to protect information and prevent man-in-the-middle attacks.

Check for Cross-Node Traffic

With large and complex application code-bases, certain queries generated by the application can often be overlooked and thus will not have the `tenant_id` filter on them. citus parallel executor will still execute these queries successfully, and so, during testing, these queries remain hidden since the application still works fine. However, if a query does not contain the `tenant_id` filter, citus executor will hit every shard in parallel, but only one will return any data. This consumes resources needlessly and may exhibit itself as a problem only when one moves to a higher-throughput production environment.

To prevent encountering such issues only after launching in production, one can set a config value to log queries, which hit more than one shard. In a properly configured and migrated multi-tenant application, each query should only hit one shard at a time.

During testing, one can configure the following:

```
-- Adjust for your own database's name of course
```

```
ALTER DATABASE citus SET citus.multi_task_query_log_level = 'error';
```

citus will then error out if it encounters queries that are going to hit more than one shard. Erroring out during testing allows the application developer to find and migrate such queries.

During a production launch, one can configure the same setting to log, instead of error out:

```
ALTER DATABASE citus SET citus.multi_task_query_log_level = 'log';
```

Visit the citus.multi_task_query_log_level section description to learn more about the supported values.

J.5.7.3.4. Migrate Production Data

At this time, having updated the database schema and application queries to work with citus, you are ready for the final step. It is time to migrate data to the citus cluster and cut over the application to its new database. The data migration procedure is presented in the Database Migration section.

J.5.7.3.4.1. Database Migration

For smaller environments that can tolerate a little downtime, use a simple pg_dump/pg_restore process. Here are the steps:

1. Save the database structure from your development database:

   ```
   pg_dump \
      --format=plain \
      --no-owner \
      --schema-only \
      --file=schema.sql \
      --schema=target_schema \
      postgres://user:pass@host:5432/db
   ```

2. Connect to the citus cluster using psql and create a schema:

   ```
   \i schema.sql
   ```

3. Call the create_distributed_table and create_reference_table functions. If you get an error about foreign keys, it is generally due to the order of operations. Drop foreign keys before distributing tables and then re-add them.

4. Put the application into maintenance mode and disable any other writes to the old database.

5. Save the data from the original production database to disk with pg_dump:

   ```
   pg_dump \
      --format=custom \
      --no-owner \
      --data-only \
      --file=data.dump \
      --schema=target_schema \
      postgres://user:pass@host:5432/db
   ```

6. Import into citus using pg_restore:

   ```
   # remember to use connection details for citus,
   # not the source database
   pg_restore  \
      --host=host \
      --dbname=dbname \
      --username=username \
      data.dump

   # it will prompt you for the connection password
   ```

7. Test application.

J.5.7.4. SQL Reference

J.5.7.4.1. Creating and Modifying Distributed Objects (DDL)

J.5.7.4.1.1. Creating and Distributing Schemas

citus supports schema-based sharding, which allows a schema to be distributed. Distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas will be automatically converted to co-located distributed tables without a shard key.

There are two ways in which a schema can be distributed in citus:

- Manually by calling the citus_schema_distribute function:

  ```
  SELECT citus_schema_distribute('user_service');
  ```

  This method also allows you to convert existing regular schemas into distributed schemas.

  > **Note**
  >
  > You can only distribute schemas that do not contain distributed and reference tables.

- Alternative approach is to enable the citus.enable_schema_based_sharding configuration parameter:

  ```
  SET citus.enable_schema_based_sharding TO ON;

  CREATE SCHEMA AUTHORIZATION user_service;
  ```

  The parameter can be changed for the current session or permanently in `postgresql.conf`. With the parameter set to `ON`, all created schemas are be distributed by default.

  The process of distributing the schema will automatically assign and move it to an existing node in the cluster. The background shard rebalancer takes these schemas and all tables within them when rebalancing the cluster, performing the optimal moves, and migrating the schemas between the nodes in the cluster.

To convert a schema back into a regular Postgres Pro schema, use the citus_schema_undistribute function:

```
SELECT citus_schema_undistribute('user_service');
```

The tables and data in the `user_service` schema will be moved from the current node back to the coordinator node in the cluster.

J.5.7.4.1.2. Creating and Distributing Tables

To create a distributed table, you need to first define the table schema. To do so, you can define a table using the `CREATE TABLE` command in the same way as you would do with a regular Postgres Pro table.

```
CREATE TABLE github_events
(
    event_id bigint,
    event_type text,
    event_public boolean,
    repo_id bigint,
    payload jsonb,
    repo jsonb,
    actor jsonb,
    org jsonb,
    created_at timestamp
);
```

Next, you can use the create_distributed_table function to specify the table distribution column and create the worker shards.

```
SELECT create_distributed_table('github_events', 'repo_id');
```

This function informs citus that the `github_events` table should be distributed on the `repo_id` column (by hashing the column value). The function also creates shards on the worker nodes using the citus.shard_count configuration parameter.

This example would create a total of `citus.shard_count` number of shards where each shard owns a portion of a hash token space. Once the shards are created, this function saves all distributed metadata on the coordinator.

Each created shard is assigned a unique `shard_id`. Each shard is represented on the worker node as a regular Postgres Pro table with the `tablename_shardid` name where `tablename` is the name of the distributed table and `shardid` is the unique ID assigned to that shard. You can connect to the worker Postgres Pro instances to view or run commands on individual shards.

You are now ready to insert data into the distributed table and run queries on it. You can also learn more about the function used in this section in the citus Utility Functions section.

Reference Tables

The above method distributes tables into multiple horizontal shards, but another possibility is distributing tables into a single shard and replicating the shard to every worker node. Tables distributed this way are called *reference tables*. They are used to store data that needs to be frequently accessed by multiple nodes in a cluster.

Common candidates for reference tables include:

- Smaller tables that need to join with larger distributed tables.
- Tables in multi-tenant apps that lack a `tenant_id` column or which are not associated with a tenant. (In some cases, to reduce migration effort, users might even choose to make reference tables out of tables associated with a tenant but which currently lack a tenant ID.)
- Tables that need unique constraints across multiple columns and are small enough.

For instance, suppose a multi-tenant eCommerce site needs to calculate sales tax for transactions in any of its stores. Tax information is not specific to any tenant. It makes sense to consolidate it in a shared table. A US-centric reference table might look like this:

```
-- A reference table

CREATE TABLE states (
  code char(2) PRIMARY KEY,
  full_name text NOT NULL,
  general_sales_tax numeric(4,3)
);

-- Distribute it to all workers

SELECT create_reference_table('states');
```

Now queries such as one calculating tax for a shopping cart can join on the `states` table with no network overhead and can add a foreign key to the state code for better validation.

In addition to distributing a table as a single replicated shard, the create_reference_table function marks it as a reference table in the citus metadata tables. citus automatically performs two-phase commits for modifications to tables marked this way, which provides strong consistency guarantees.

If you have an existing distributed table, you can change it to a reference table by running:

```
SELECT undistribute_table('table_name');
SELECT create_reference_table('table_name');
```

For another example of using reference tables in a multi-tenant application, see the Sharing Data Between Tenants section.

Distributing Coordinator Data

If an existing Postgres Pro database is converted into the coordinator node for a citus cluster, the data in its tables can be distributed efficiently and with minimal interruption to an application.

The create_distributed_table function described earlier works on both empty and non-empty tables and for the latter it automatically distributes table rows throughout the cluster. You will know if it does this by the presence of the following message: `NOTICE: Copying data from local table...`. For example:

```
CREATE TABLE series AS SELECT i FROM generate_series(1,1000000) i;
SELECT create_distributed_table('series', 'i');
NOTICE:  Copying data from local table...
NOTICE:  copying the data has completed
DETAIL:  The local data in the table is no longer visible, but is still on disk.
HINT:  To remove the local data, run: SELECT
 truncate_local_data_after_distributing_table($$public.series$$)
 create_distributed_table
 --------------------------

 (1 row)
```

Writes on the table are blocked while the data is migrated, and pending writes are handled as distributed queries once the function commits. (If the function fails, then the queries become local again.) Reads can continue as normal and will become distributed queries once the function commits.

When distributing tables A and B, where A has a foreign key to B, distribute the key destination table B first. Doing it in the wrong order will cause an error:

```
ERROR:  cannot create foreign key constraint
DETAIL:  Referenced table must be a distributed table or a reference table.
```

If it is not possible to distribute in the correct order, then drop the foreign keys, distribute the tables, and recreate the foreign keys.

After the tables are distributed, use the truncate_local_data_after_distributing_table function to remove local data. Leftover local data in distributed tables is inaccessible to citus queries and can cause irrelevant constraint violations on the coordinator.

J.5.7.4.1.3. Co-Locating Tables

Co-location is the practice of dividing data tactically, keeping related information on the same computers to enable efficient relational operations, while taking advantage of the horizontal scalability for the whole dataset. For more information and examples, see the Table Co-Location section.

Tables are co-located in groups. To manually control a table's co-location group assignment use the optional `colocate_with` parameter of the create_distributed_table function. If you do not care about a table's co-location, then omit this parameter. It defaults to the value `'default'`, which groups the table with any other default co-location table having the same distribution column type and shard count. If you want to break or update this implicit co-location, you can use the update_distributed_table_colocation function.

```
-- These tables are implicitly co-located by using the same
-- distribution column type and shard count with the default
-- co-location group

SELECT create_distributed_table('A', 'some_int_col');
SELECT create_distributed_table('B', 'other_int_col');
```

When a new table is not related to others in its would-be implicit co-location group, specify `colocated_with => 'none'`.

```
-- Not co-located with other tables

SELECT create_distributed_table('A', 'foo', colocate_with => 'none');
```

Splitting unrelated tables into their own co-location groups will improve shard rebalancing performance, because shards in the same group have to be moved together.

When tables are indeed related (for instance when they will be joined), it can make sense to explicitly co-locate them. The gains of appropriate co-location are more important than any rebalancing overhead.

To explicitly co-locate multiple tables, distribute one and then put the others into its co-location group. For example:

```
-- Distribute stores
SELECT create_distributed_table('stores', 'store_id');

-- Add to the same group as stores
SELECT create_distributed_table('orders', 'store_id', colocate_with => 'stores');
SELECT create_distributed_table('products', 'store_id', colocate_with => 'stores');
```

Information about co-location groups is stored in the pg_dist_colocation table, while the pg_dist_partition table reveals which tables are assigned to which groups.

J.5.7.4.1.4. Dropping Tables

You can use the standard Postgres Pro `DROP TABLE` command to remove your distributed tables. As with regular tables, `DROP TABLE` removes any indexes, rules, triggers, and constraints that exist for the target table. In addition, it also drops the shards on the worker nodes and cleans up their metadata.

```
DROP TABLE github_events;
```

J.5.7.4.1.5. Modifying Tables

citus automatically propagates many kinds of DDL statements, which means that modifying a distributed table on the coordinator node will update shards on the workers too. Other DDL statements require manual propagation, and certain others are prohibited such as those which would modify a distribution column. Attempting to run DDL that is ineligible for automatic propagation will raise an error and leave tables on the coordinator node unchanged.

Here is a reference of the categories of DDL statements, which propagate. Note that automatic propagation can be enabled or disabled with the citus.enable_ddl_propagation configuration parameter.

Adding/Modifying Columns

citus propagates most `ALTER TABLE` commands automatically. Adding columns or changing their default values work as they would in a single-machine Postgres Pro database:

```
-- Adding a column

ALTER TABLE products ADD COLUMN description text;

-- Changing default value

ALTER TABLE products ALTER COLUMN price SET DEFAULT 7.77;
```

Significant changes to an existing column like renaming it or changing its data type are fine too. However, the data type of the distribution column cannot be altered. This column determines how table data distributes through the citus cluster, and modifying its data type would require moving the data.

Attempting to do so causes an error:

```
-- Assuming store_id is the distribution column
-- for products and that it has type integer

ALTER TABLE products
```

```
ALTER COLUMN store_id TYPE text;

/*
ERROR:  cannot execute ALTER TABLE command involving partition column
*/
```

As a workaround, you can consider changing the distribution column using the alter_distributed_table function, updating it, and changing it back.

Adding/Removing Constraints

Using citus allows you to continue to enjoy the safety of a relational database, including database constraints. Due to the nature of distributed systems, citus will not cross-reference uniqueness constraints or referential integrity between worker nodes.

To set up a foreign key between co-located distributed tables, always include the distribution column in the key. This may involve making the key compound.

Foreign keys may be created in these situations:

- between two local (non-distributed) tables,
- between two reference tables,
- between reference tables and local tables (by default enabled via the citus.enable_local_reference_table_foreign_keys configuration parameter),
- between two co-located distributed tables when the key includes the distribution column, or
- as a distributed table referencing a reference table.

Foreign keys from reference tables to distributed tables are not supported.

citus supports all referential actions on foreign keys from local to reference tables but does not support `ON DELETE`/`ON UPDATE CASCADE` in the reverse direction (reference to local).

> **Note**
>
> Primary keys and uniqueness constraints must include the distribution column. Adding them to a non-distribution column will generate the creating unique indexes on non-partition columns is currently unsupported error.

This example shows how to create primary and foreign keys on distributed tables:

```
--
-- Adding a primary key
-- --------------------

-- We will distribute these tables on the account_id. The ads and clicks
-- tables must use compound keys that include account_id

ALTER TABLE accounts ADD PRIMARY KEY (id);
ALTER TABLE ads ADD PRIMARY KEY (account_id, id);
ALTER TABLE clicks ADD PRIMARY KEY (account_id, id);

-- Next distribute the tables

SELECT create_distributed_table('accounts', 'id');
SELECT create_distributed_table('ads',      'account_id');
SELECT create_distributed_table('clicks',   'account_id');

--
-- Adding foreign keys
```

```
-- ------------------

-- Note that this can happen before or after distribution, as long as
-- there exists a uniqueness constraint on the target column(s), which
-- can only be enforced before distribution

ALTER TABLE ads ADD CONSTRAINT ads_account_fk
  FOREIGN KEY (account_id) REFERENCES accounts (id);
ALTER TABLE clicks ADD CONSTRAINT clicks_ad_fk
  FOREIGN KEY (account_id, ad_id) REFERENCES ads (account_id, id);
```

Similarly, include the distribution column in uniqueness constraints:

```
-- Suppose we want every ad to use a unique image. Notice we can
-- enforce it only per account when we distribute by account_id

ALTER TABLE ads ADD CONSTRAINT ads_unique_image
  UNIQUE (account_id, image_url);
```

Not-null constraints can be applied to any column (distribution or not) because they require no lookups between workers.

```
ALTER TABLE ads ALTER COLUMN image_url SET NOT NULL;
```

Using `NOT VALID` Constraints

In some situations it can be useful to enforce constraints for new rows, while allowing existing non-conforming rows to remain unchanged. citus supports this feature for the `CHECK` constraints and foreign keys using the Postgres Pro `NOT VALID` constraint designation.

For example, consider an application that stores user profiles in a reference table.

```
-- We are using the "text" column type here, but a real application
-- might use "citext", which is available in the
-- Postgres Pro contrib module

CREATE TABLE users ( email text PRIMARY KEY );
SELECT create_reference_table('users');
```

In the course of time imagine that a few non-addresses get into the table.

```
INSERT INTO users VALUES
   ('foo@example.com'), ('hacker12@aol.com'), ('lol');
```

We would like to validate the addresses, but Postgres Pro does not ordinarily allow us to add the `CHECK` constraint that fails for existing rows. However, it *does* allow a constraint marked `NOT VALID`:

```
ALTER TABLE users
ADD CONSTRAINT syntactic_email
CHECK (email ~
   '^[a-zA-Z0-9.!#$%&''*+/=?^_`{|}~-]+@[a-zA-Z0-9](?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])?(?:
\.[a-zA-Z0-9](?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])?)*$'
) NOT VALID;
```

This succeeds, and new rows are protected.

```
INSERT INTO users VALUES ('fake');

/*
ERROR:  new row for relation "users_102010" violates
        check constraint "syntactic_email_102010"
DETAIL:  Failing row contains (fake).
*/
```

Later, during non-peak hours, a database administrator can attempt to fix the bad rows and re-validate the constraint.

```
-- Later, attempt to validate all rows
ALTER TABLE users
VALIDATE CONSTRAINT syntactic_email;
```

The Postgres Pro documentation has more information about `NOT VALID` and `VALIDATE CONSTRAINT` in the section about the `ALTER TABLE` command.

Adding/Removing Indices

citus supports adding and removing indices:

```
-- Adding an index

CREATE INDEX clicked_at_idx ON clicks USING BRIN (clicked_at);

-- Removing an index

DROP INDEX clicked_at_idx;
```

Adding an index takes a write lock, which can be undesirable in a multi-tenant “system-of-record”. To minimize application downtime, create the index concurrently instead. This method requires more total work than a standard index build and takes significantly longer to complete. However, since it allows normal operations to continue while the index is built, this method is useful for adding new indexes in a production environment.

```
-- Adding an index without locking table writes

CREATE INDEX CONCURRENTLY clicked_at_idx ON clicks USING BRIN (clicked_at);
```

J.5.7.4.1.6. Types and Functions

Creating custom SQL types and user-defined functions propogates to worker nodes. However, creating such database objects in a transaction with distributed operations involves tradeoffs.

citus parallelizes operations such as create_distributed_table across shards using multiple connections per worker. Whereas, when creating a database object, citus propagates it to worker nodes using a single connection per worker. Combining the two operations in a single transaction may cause issues, because the parallel connections will not be able to see the object that was created over a single connection but not yet committed.

Consider a transaction block that creates a type, a table, loads data, and distributes the table:

```
BEGIN;

-- Type creation over a single connection:
CREATE TYPE coordinates AS (x int, y int);
CREATE TABLE positions (object_id text primary key, position coordinates);

-- Data loading thus goes over a single connection:
SELECT create_distributed_table('positions', 'object_id');
\COPY positions FROM 'positions.csv'

COMMIT;
```

citus default behaviour prioritizes schema consistency between coordinator and worker nodes. This behavior has a downside: if object propagation happens after a parallel command in the same transaction, then the transaction can no longer be completed, as highlighted by the `ERROR` in the code block below:

```
BEGIN;
CREATE TABLE items (key text, value text);
```

```
-- Parallel data loading:
SELECT create_distributed_table('items', 'key');
\COPY items FROM 'items.csv'
CREATE TYPE coordinates AS (x int, y int);

ERROR:  cannot run type command because there was a parallel operation on a distributed
 table in the transaction
```

If you run into this issue, there is a simple workaround: use the `citus.multi_shard_modify_mode` parameter set to `sequential` to disable per-node parallelism. Data load in the same transaction might be slower.

J.5.7.4.1.7. Manual Modification

Most DDL commands are auto-propagated. For any others, you can propagate the changes manually. See the Manual Query Propagation section.

J.5.7.4.2. Ingesting, Modifying Data (DML)

J.5.7.4.2.1. Inserting Data

To insert data into distributed tables, you can use the standard Postgres Pro `INSERT` command. As an example, we pick two rows randomly from the `GitHub Archive` dataset.

```
/*
CREATE TABLE github_events
(
  event_id bigint,
  event_type text,
  event_public boolean,
  repo_id bigint,
  payload jsonb,
  repo jsonb,
  actor jsonb,
  org jsonb,
  created_at timestamp
);
*/

INSERT INTO github_events VALUES (2489373118,'PublicEvent','t',24509048,'{}','{"id":
 24509048, "url": "https://api.github.com/repos/SabinaS/csee6868", "name": "SabinaS/
csee6868"}','{"id": 2955009, "url": "https://api.github.com/users/SabinaS", "login":
 "SabinaS", "avatar_url": "https://avatars.githubusercontent.com/u/2955009?",
 "gravatar_id": ""}',NULL,'2015-01-01 00:09:13');

INSERT INTO github_events VALUES (2489368389,'WatchEvent','t',28229924,'{"action":
 "started"}','{"id": 28229924, "url": "https://api.github.com/repos/inf0rmer/
blanket", "name": "inf0rmer/blanket"}','{"id": 1405427, "url": "https://
api.github.com/users/tategakibunko", "login": "tategakibunko", "avatar_url": "https://
avatars.githubusercontent.com/u/1405427?", "gravatar_id": ""}',NULL,'2015-01-01
 00:00:24');
```

When inserting rows into distributed tables, the distribution column of the row being inserted must be specified. Based on the distribution column, citus determines the right shard to which the insert should be routed to. Then, the query is forwarded to the right shard, and the remote `INSERT` command is executed on all the replicas of that shard.

Sometimes it is convenient to put multiple `INSERT` statements together into a single `INSERT` of multiple rows. It can also be more efficient than making repeated database queries. For instance, the example from the previous section can be loaded all at once like this:

```
INSERT INTO github_events VALUES
```

```
  (
    2489373118,'PublicEvent','t',24509048,'{}','{"id": 24509048, "url": "https://
api.github.com/repos/SabinaS/csee6868", "name": "SabinaS/csee6868"}','{"id":
 2955009, "url": "https://api.github.com/users/SabinaS", "login": "SabinaS",
 "avatar_url": "https://avatars.githubusercontent.com/u/2955009?", "gravatar_id":
 ""}',NULL,'2015-01-01 00:09:13'
  ), (
    2489368389,'WatchEvent','t',28229924,'{"action": "started"}','{"id": 28229924,
 "url": "https://api.github.com/repos/inf0rmer/blanket", "name": "inf0rmer/
blanket"}','{"id": 1405427, "url": "https://api.github.com/users/tategakibunko",
 "login": "tategakibunko", "avatar_url": "https://avatars.githubusercontent.com/
u/1405427?", "gravatar_id": ""}',NULL,'2015-01-01 00:00:24'
  );
```

Distributed Rollups

citus also supports `INSERT … SELECT` statements, which insert rows based on the results of the `SELECT` query. This is a convenient way to fill tables and also allows UPSERTS with the `ON CONFLICT` clause, the easiest way to do distributed rollups.

In citus there are three ways that inserting from the `SELECT` statement can happen:

- The first is if the source tables and the destination table are co-located and the `SELECT/INSERT` statements both include the distribution column. In this case, citus can push the `INSERT … SELECT` statement down for parallel execution on all nodes.
- The second way of executing the `INSERT … SELECT` statement is by repartitioning the results of the result set into chunks, and sending those chunks among workers to matching destination table shards. Each worker node can insert the values into local destination shards.

  The repartitioning optimization can happen when the `SELECT` query does not require a merge step on the coordinator. It does nor work with the following SQL features, which require a merge step:

  - `ORDER BY`
  - `LIMIT`
  - `OFFSET`
  - `GROUP BY` when distribution column is not part of the group key
  - Window functions when partitioning by a non-distribution column in the source table(s)
  - Joins between non-colocated tables (i.e. repartition joins)
- When the source and destination tables are not co-located and the repartition optimization cannot be applied, then citus uses the third way of executing `INSERT … SELECT`. It selects the results from worker nodes and pulls the data up to the coordinator node. The coordinator redirects rows back down to the appropriate shard. Because all the data must pass through a single node, this method is not as efficient.

When in doubt about which method citus is using, use the `EXPLAIN` command, as described in the Postgres Pro Tuning section. When the target table has a very large shard count, it may be wise to disable repartitioning, see the citus.enable_repartitioned_insert_select configuration parameter.

The `\copy` Command (Bulk Load)

To bulk load data from a file, you can directly use the `\copy` command.

First download our example `github_events` dataset by running:

```
wget http://examples.citusdata.com/github_archive/github_events-2015-01-01-
{0..5}.csv.gz
gzip -d github_events-2015-01-01-*.gz
```

Then, you can copy the data using psql. Note that this data requires the database to have UTF-8 encoding:

```
\COPY github_events FROM 'github_events-2015-01-01-0.csv' WITH (format CSV)
```

> **Note**
>
> There is no notion of snapshot isolation across shards, which means that a multi-shard `SELECT` that runs concurrently with the `\copy` command might see it committed on some shards, but not on others. If the user is storing events data, he may occasionally observe small gaps in recent data. It is up to applications to deal with this if it is a problem (e.g. exclude the most recent data from queries or use some lock).
>
> If `\copy` fails to open a connection for a shard placement, then it behaves in the same way as `INSERT`, namely to mark the placement(s) as inactive unless there are no more active placements. If any other failure occurs after connecting, the transaction is rolled back and thus no metadata changes are made.

J.5.7.4.3. Caching Aggregations with Rollups

Applications like event data pipelines and real-time dashboards require sub-second queries on large volumes of data. One way to make these queries fast is by calculating and saving aggregates ahead of time. This is called “rolling up” the data and it avoids the cost of processing raw data at run-time. As an extra benefit, rolling up timeseries data into hourly or daily statistics can also save space. Old data may be deleted when its full details are no longer needed and aggregates suffice.

For example, here is a distributed table for tracking page views by URL:

```
CREATE TABLE page_views (
  site_id int,
  url text,
  host_ip inet,
  view_time timestamp default now(),

  PRIMARY KEY (site_id, url)
);

SELECT create_distributed_table('page_views', 'site_id');
```

Once the table is populated with data, we can run an aggregate query to count page views per URL per day, restricting to a given site and year.

```
-- How many views per url per day on site 5?
SELECT view_time::date AS day, site_id, url, count(*) AS view_count
  FROM page_views
  WHERE site_id = 5 AND
    view_time >= date '2016-01-01' AND view_time < date '2017-01-01'
  GROUP BY view_time::date, site_id, url;
```

The setup described above works but has two drawbacks. First, when you repeatedly execute the aggregate query, it must go over each related row and recompute the results for the entire data set. If you are using this query to render a dashboard, it is faster to save the aggregated results in a daily page views table and query that table. Second, storage costs will grow proportionally with data volumes and the length of queryable history. In practice, you may want to keep raw events for a short time period and look at historical graphs over a longer time window.

To receive those benefits, we can create the `daily_page_views` table to store the daily statistics.

```
CREATE TABLE daily_page_views (
  site_id int,
  day date,
  url text,
  view_count bigint,
```

```
  PRIMARY KEY (site_id, day, url)
);

SELECT create_distributed_table('daily_page_views', 'site_id');
```

In this example, we distributed both `page_views` and `daily_page_views` on the `site_id` column. This ensures that data corresponding to a particular site will be co-located on the same node. Keeping the rows of the two tables together on each node minimizes network traffic between nodes and enables highly parallel execution.

Once we create this new distributed table, we can then run `INSERT INTO ... SELECT` to roll up raw page views into the aggregated table. In the following, we aggregate page views each day. citus users often wait for a certain time period after the end of day to run a query like this, to accommodate late arriving data.

```
-- Roll up yesterday's data
INSERT INTO daily_page_views (day, site_id, url, view_count)
  SELECT view_time::date AS day, site_id, url, count(*) AS view_count
  FROM page_views
  WHERE view_time >= date '2017-01-01' AND view_time < date '2017-01-02'
  GROUP BY view_time::date, site_id, url;

-- Now the results are available right out of the table
SELECT day, site_id, url, view_count
  FROM daily_page_views
  WHERE site_id = 5 AND
    day >= date '2016-01-01' AND day < date '2017-01-01';
```

The rollup query above aggregates data from the previous day and inserts it into the `daily_page_views` table. Running the query once each day means that no rollup tables rows need to be updated, because the new day's data does not affect previous rows.

The situation changes when dealing with late arriving data, or running the rollup query more than once per day. If any new rows match days already in the rollup table, the matching counts should increase. Postgres Pro can handle this situation with `ON CONFLICT`, which is its technique for doing UPSERTS. Here is an example.

```
-- Roll up from a given date onward,
-- updating daily page views when necessary
INSERT INTO daily_page_views (day, site_id, url, view_count)
  SELECT view_time::date AS day, site_id, url, count(*) AS view_count
  FROM page_views
  WHERE view_time >= date '2017-01-01'
  GROUP BY view_time::date, site_id, url
  ON CONFLICT (day, url, site_id) DO UPDATE SET
    view_count = daily_page_views.view_count + EXCLUDED.view_count;
```

J.5.7.4.3.1. Updates and Deletion

You can update or delete rows from your distributed tables using the standard Postgres Pro `UPDATE` and `DELETE` commands.

```
DELETE FROM github_events
WHERE repo_id IN (24509048, 24509049);

UPDATE github_events
SET event_public = TRUE
WHERE (org->>'id')::int = 5430905;
```

When the `UPDATE`/`DELETE` operations affect multiple shards as in the above example, citus defaults to using a one-phase commit protocol. For greater safety you can enable two-phase commits by setting the `citus.multi_shard_commit_protocol` configuration parameter:

```
SET citus.multi_shard_commit_protocol = '2pc';
```

If an UPDATE or DELETE operation affects only a single shard, then it runs within a single worker node. In this case enabling 2PC is unnecessary. This often happens when updates or deletes filter by a table's distribution column:

```
-- Since github_events is distributed by repo_id,
-- this will execute in a single worker node

DELETE FROM github_events
WHERE repo_id = 206084;
```

Furthermore, when dealing with a single shard, citus supports SELECT … FOR UPDATE. This is a technique sometimes used by object-relational mappers (ORMs) to safely:

- Load rows
- Make a calculation in application code
- Update the rows based on calculation

Selecting the rows for update puts a write lock on them to prevent other processes from causing the “lost update” anomaly.

```
BEGIN;

  -- Select events for a repo, but
  -- lock them for writing
  SELECT *
  FROM github_events
  WHERE repo_id = 206084
  FOR UPDATE;

  -- Calculate a desired value event_public using
  -- application logic that uses those rows

  -- Now make the update
  UPDATE github_events
  SET event_public = :our_new_value
  WHERE repo_id = 206084;

COMMIT;
```

This feature is supported for hash distributed and reference tables only.

J.5.7.4.3.2. Maximizing Write Performance

Both INSERT and UPDATE/DELETE statements can be scaled up to around 50,000 queries per second on large machines. However, to achieve this rate, you will need to use many parallel, long-lived connections and consider how to deal with locking. For more information, you can consult the Scaling Out Data Ingestion section.

J.5.7.4.4. Querying Distributed Tables (SQL)

As discussed in the previous sections, citus extends the latest Postgres Pro for distributed execution. This means that you can use standard Postgres Pro SELECT queries on the citus coordinator. The extension will then parallelize the SELECT queries involving complex selections, groupings and orderings, and JOINs to speed up the query performance. At a high level, citus partitions the SELECT query into smaller query fragments, assigns these query fragments to workers, oversees their execution, merges their results (and orders them if needed), and returns the final result to the user.

In the following sections, we discuss the different types of queries you can run using citus.

J.5.7.4.4.1. Aggregate Functions

citus supports and parallelizes most aggregate functions supported by Postgres Pro, including custom user-defined aggregates. Aggregates execute using one of three methods, in this order of preference:

- When the aggregate is grouped by a distribution column of a table, citus can push down execution of the entire query to each worker. All aggregates are supported in this situation and execute in parallel on the worker nodes. (Any custom aggregates being used must be installed on the workers.)
- When the aggregate is *not* grouped by a distribution column, citus can still optimize on a case-by-case basis. citus has internal rules for certain aggregates like `sum()`, `avg()`, and `count(distinct)` that allow it to rewrite queries for *partial aggregation* on workers. For instance, to calculate an average, citus obtains a sum and a count from each worker, and then the coordinator node computes the final average.

  Full list of the special-case aggregates:

  `avg`, `min`, `max`, `sum`, `count`, `array_agg`, `jsonb_agg`, `jsonb_object_agg`, `json_agg`, `json_object_agg`, `bit_and`, `bit_or`, `bool_and`, `bool_or`, `every`, `hll_add_agg`, `hll_union_agg`, `topn_add_agg`, `topn_union_agg`, `any_value`, `tdigest(double precision, int)`, `tdigest_percentile(double precision, int, double precision)`, `tdigest_percentile(double precision, int, double precision[])`, `tdigest_percentile(tdigest, double precision)`, `tdigest_percentile(tdigest, double precision[])`, `tdigest_percentile_of(double precision, int, double precision)`, `tdigest_percentile_of(double precision, int, double precision[])`, `tdigest_percentile_of(tdigest, double precision)`, `tdigest_percentile_of(tdigest, double precision[])`
- Last resort: pull all rows from the workers and perform the aggregation on the coordinator node. When the aggregate is not grouped on a distribution column, and is not one of the predefined special cases, then citus falls back to this approach. It causes network overhead and can exhaust the coordinator resources if the data set to be aggregated is too large. (It is possible to disable this fallback, see below.)

Beware that small changes in a query can change execution modes causing potentially surprising inefficiency. For example, `sum(x)` grouped by a non-distribution column could use distributed execution, while `sum(distinct x)` has to pull up the entire set of input records to the coordinator.

All it takes is one column to hurt the execution of a whole query. In the example below, if `sum(distinct value2)` has to be grouped on the coordinator, then so will `sum(value1)` even if the latter was fine on its own.

```
SELECT sum(value1), sum(distinct value2) FROM distributed_table;
```

To avoid accidentally pulling data to the coordinator, you can set the `citus.coordinator_aggregation_strategy` parameter:

```
SET citus.coordinator_aggregation_strategy TO 'disabled';
```

Note that disabling the coordinator aggregation strategy will prevent “type three” aggregate queries from working at all.

The `count(distinct)` Aggregates

citus supports `count(distinct)` aggregates in several ways. If the `count(distinct)` aggregate is on the distribution column, citus can directly push down the query to the workers. If not, citus runs `SELECT` distinct statements on each worker and returns the list to the coordinator where it obtains the final count.

Note that transferring this data becomes slower when workers have a greater number of distinct items. This is especially true for queries containing multiple `count(distinct)` aggregates, e.g.:

```
-- Multiple distinct counts in one query tend to be slow
SELECT count(distinct a), count(distinct b), count(distinct c)
```

```
FROM table_abc;
```

For these kind of queries, the resulting `SELECT` distinct statements on the workers essentially produce a cross-product of rows to be transferred to the coordinator.

For increased performance you can choose to make an approximate count instead. Follow the steps below:

1. Download and install the hll extension on all Postgres Pro instances (the coordinator and all the workers).

   You can visit the hll *GitHub repository* for specifics on obtaining the extension.

2. Create the hll extension on all the Postgres Pro instances by simply running the below command from the coordinator:

   ```
   CREATE EXTENSION hll;
   ```

3. Enable `count(distinct)` approximations by setting the citus.count_distinct_error_rate configuration parameter. Lower values for this configuration setting are expected to give more accurate results but take more time for computation. We recommend setting this to `0.005`.

   ```
   SET citus.count_distinct_error_rate TO 0.005;
   ```

   After this step, `count(distinct)` aggregates automatically switch to using hll with no changes necessary to your queries. You should be able to run approximate `count(distinct)` queries on any column of the table.

HyperLogLog Column. Certain users already store their data as hll columns. In such cases, they can dynamically roll up those data by calling the `hll_union_agg(hll_column)` function.

Estimating Top N Items

Calculating the first *n* elements in a set by applying `count`, `sort`, and `limit` is simple. However, as data sizes increase, this method becomes slow and resource intensive. It is more efficient to use an approximation.

The open source *topn* extension for Postgres Pro enables fast approximate results to “top-n” queries. The extension materializes the top values into a `json` data type. The topn extension can incrementally update these top values or merge them on-demand across different time intervals.

Before seeing a realistic example of topn, let's see how some of its primitive operations work. First `topn_add` updates a JSON object with counts of how many times a key has been seen:

```
-- Starting from nothing, record that we saw an "a"
SELECT topn_add('{}', 'a');
-- => {"a": 1}

-- Record the sighting of another "a"
SELECT topn_add(topn_add('{}', 'a'), 'a');
-- => {"a": 2}
```

The extension also provides aggregations to scan multiple values:

```
-- For normal_rand
CREATE EXTENSION tablefunc;

-- Count values from a normal distribution
SELECT topn_add_agg(floor(abs(i))::text)
  FROM normal_rand(1000, 5, 0.7) i;
-- => {"2": 1, "3": 74, "4": 420, "5": 425, "6": 77, "7": 3}
```

If the number of distinct values crosses a threshold, the aggregation drops information for those seen least frequently. This keeps space usage under control. The threshold can be controlled by the `topn.number_of_counters` configuration parameter. Its default value is `1000`.

Now onto a more realistic example of how topn works in practice. Let's ingest Amazon product reviews from the year 2000 and use topn to query it quickly. First download the dataset:

```
curl -L https://examples.citusdata.com/customer_reviews_2000.csv.gz | \
  gunzip > reviews.csv
```

Next, ingest it into a distributed table:

```
CREATE TABLE customer_reviews
(
    customer_id TEXT,
    review_date DATE,
    review_rating INTEGER,
    review_votes INTEGER,
    review_helpful_votes INTEGER,
    product_id CHAR(10),
    product_title TEXT,
    product_sales_rank BIGINT,
    product_group TEXT,
    product_category TEXT,
    product_subcategory TEXT,
    similar_product_ids CHAR(10)[]
);

SELECT create_distributed_table('customer_reviews', 'product_id');

\COPY customer_reviews FROM 'reviews.csv' WITH CSV
```

Next we will add the extension, create a destination table to store the JSON data generated by topn, and apply the `topn_add_agg` function we saw previously.

```
-- Run below command from coordinator, it will be propagated to the worker nodes as
 well
CREATE EXTENSION topn;

-- A table to materialize the daily aggregate
CREATE TABLE reviews_by_day
(
  review_date date unique,
  agg_data jsonb
);

SELECT create_reference_table('reviews_by_day');

-- Materialize how many reviews each product got per day per customer
INSERT INTO reviews_by_day
  SELECT review_date, topn_add_agg(product_id)
  FROM customer_reviews
  GROUP BY review_date;
```

Now, rather than writing a complex window function on `customer_reviews`, we can simply apply topn to `reviews_by_day`. For instance, the following query finds the most frequently reviewed product for each of the first five days:

```
SELECT review_date, (topn(agg_data, 1)).*
FROM reviews_by_day
ORDER BY review_date
LIMIT 5;
```

```
┌─────────────┬──────────────┬─────────────┐
│ review_date │     item     │ frequency │
```

```
┌──────────────┬──────────────┬──────────────┐
│ 2000-01-01   │ 0939173344   │           12 │
│ 2000-01-02   │ B000050XY8   │           11 │
│ 2000-01-03   │ 0375404368   │           12 │
│ 2000-01-04   │ 0375408738   │           14 │
│ 2000-01-05   │ B00000J7J4   │           17 │
└──────────────┴──────────────┴──────────────┘
```

The JSON fields created by topn can be merged with `topn_union` and `topn_union_agg`. We can use the latter to merge the data for the entire first month and list the five most reviewed products during that period.

```
SELECT (topn(topn_union_agg(agg_data), 5)).*
FROM reviews_by_day
WHERE review_date >= '2000-01-01' AND review_date < '2000-02-01'
ORDER BY 2 DESC;
```

```
┌──────────────┬──────────────┐
│     item     │  frequency   │
├──────────────┼──────────────┤
│ 0375404368   │          217 │
│ 0345417623   │          217 │
│ 0375404376   │          217 │
│ 0375408738   │          217 │
│ 043936213X   │          204 │
└──────────────┴──────────────┘
```

For more details and examples, see the *topn readme file*.

Percentile Calculations

Finding an exact percentile over a large number of rows can be prohibitively expensive, because all rows must be transferred to the coordinator for final sorting and processing. Finding an approximation, on the other hand, can be done in parallel on worker nodes using a so-called *sketch algorithm*. The coordinator node then combines compressed summaries into the final result rather than reading through the full rows.

A popular sketch algorithm for percentiles uses a compressed data structure called *t-digest*, and is available for Postgres Pro in the *tdigest* extension. citus has integrated support for this extension.

Here is how to use tdigest in citus:

1. Download and install the tdigest extension on all Postgres Pro nodes (the coordinator and all the workers). The *tdigest extension GitHub repository* has installation instructions.
2. Create the tdigest extension within the database. Run the following command on the coordinator:

   ```
   CREATE EXTENSION tdigest;
   ```

   The coordinator will propagate the command to the workers as well.

When any of the aggregates defined in the extension are used in queries, citus will rewrite the queries to push down partial tdigest computation to the workers where applicable.

tdigest accuracy can be controlled with the `compression` argument passed into aggregates. The trade-off is accuracy vs the amount of data shared between workers and the coordinator. For a full explanation of how to use the aggregates in tdigest, have a look at the documentation of the extension.

J.5.7.4.4.2. Limit Pushdown

citus also pushes down the limit clauses to the shards on the workers wherever possible to minimize the amount of data transferred across network.

However, in some cases, `SELECT` queries with `LIMIT` clauses may need to fetch all rows from each shard to generate exact results. For example, if the query requires ordering by the aggregate column, it would

need results of that column from all shards to determine the final aggregate value. This reduces performance of the `LIMIT` clause due to high volume of network data transfer. In such cases, and where an approximation would produce meaningful results, citus provides an option for network efficient approximate `LIMIT` clauses.

`LIMIT` approximations are disabled by default and can be enabled by setting the citus.limit_clause_row_fetch_count configuration parameter. On the basis of this configuration value, citus will limit the number of rows returned by each task for aggregation on the coordinator. Due to this limit, the final results may be approximate. Increasing this limit will increase the accuracy of the final results, while still providing an upper bound on the number of rows pulled from the workers.

```
SET citus.limit_clause_row_fetch_count TO 10000;
```

J.5.7.4.4.3. Views on Distributed Tables

citus supports all views on distributed tables. To learn more about syntax and features of views, see the section about the `CREATE VIEW` command.

Note that some views cause a less efficient query plan than others. For more information about detecting and improving poor view performance, see the Subquery/CTE Network Overhead section. (Views are treated inside the extension as subqueries.)

citus supports materialized views as well and stores them as local tables on the coordinator node.

J.5.7.4.4.4. Joins

citus supports equi-joins between any number of tables irrespective of their size and distribution method. The query planner chooses the optimal join method and join order based on how tables are distributed. It evaluates several possible join orders and creates a join plan which requires minimum data to be transferred across network.

Co-Located Joins

When two tables are co-located then they can be joined efficiently on their common distribution columns. A co-located join is the most efficient way to join two large distributed tables.

Internally, the citus coordinator knows which shards of the co-located tables might match with shards of the other table by looking at the distribution column metadata. This allows citus to prune away shard pairs, which cannot produce matching join keys. The joins between remaining shard pairs are executed in parallel on the workers and then the results are returned to the coordinator.

> **Note**
>
> Be sure that the tables are distributed into the same number of shards and that the distribution columns of each table have exactly matching types. Attempting to join on columns of slightly different types such as `int` and `bigint` can cause problems.

Reference Table Joins

Reference tables can be used as “dimension” tables to join efficiently with large “fact” tables. Because reference tables are replicated in full across all worker nodes, a reference join can be decomposed into local joins on each worker and performed in parallel. A reference join is like a more flexible version of a co-located join because reference tables are not distributed on any particular column and are free to join on any of their columns.

Reference tables can also join with tables local to the coordinator node.

Repartition Joins

In some cases, you may need to join two tables on columns other than the distribution column. For such cases, citus also allows joining on non-distribution key columns by dynamically repartitioning the tables for the query.

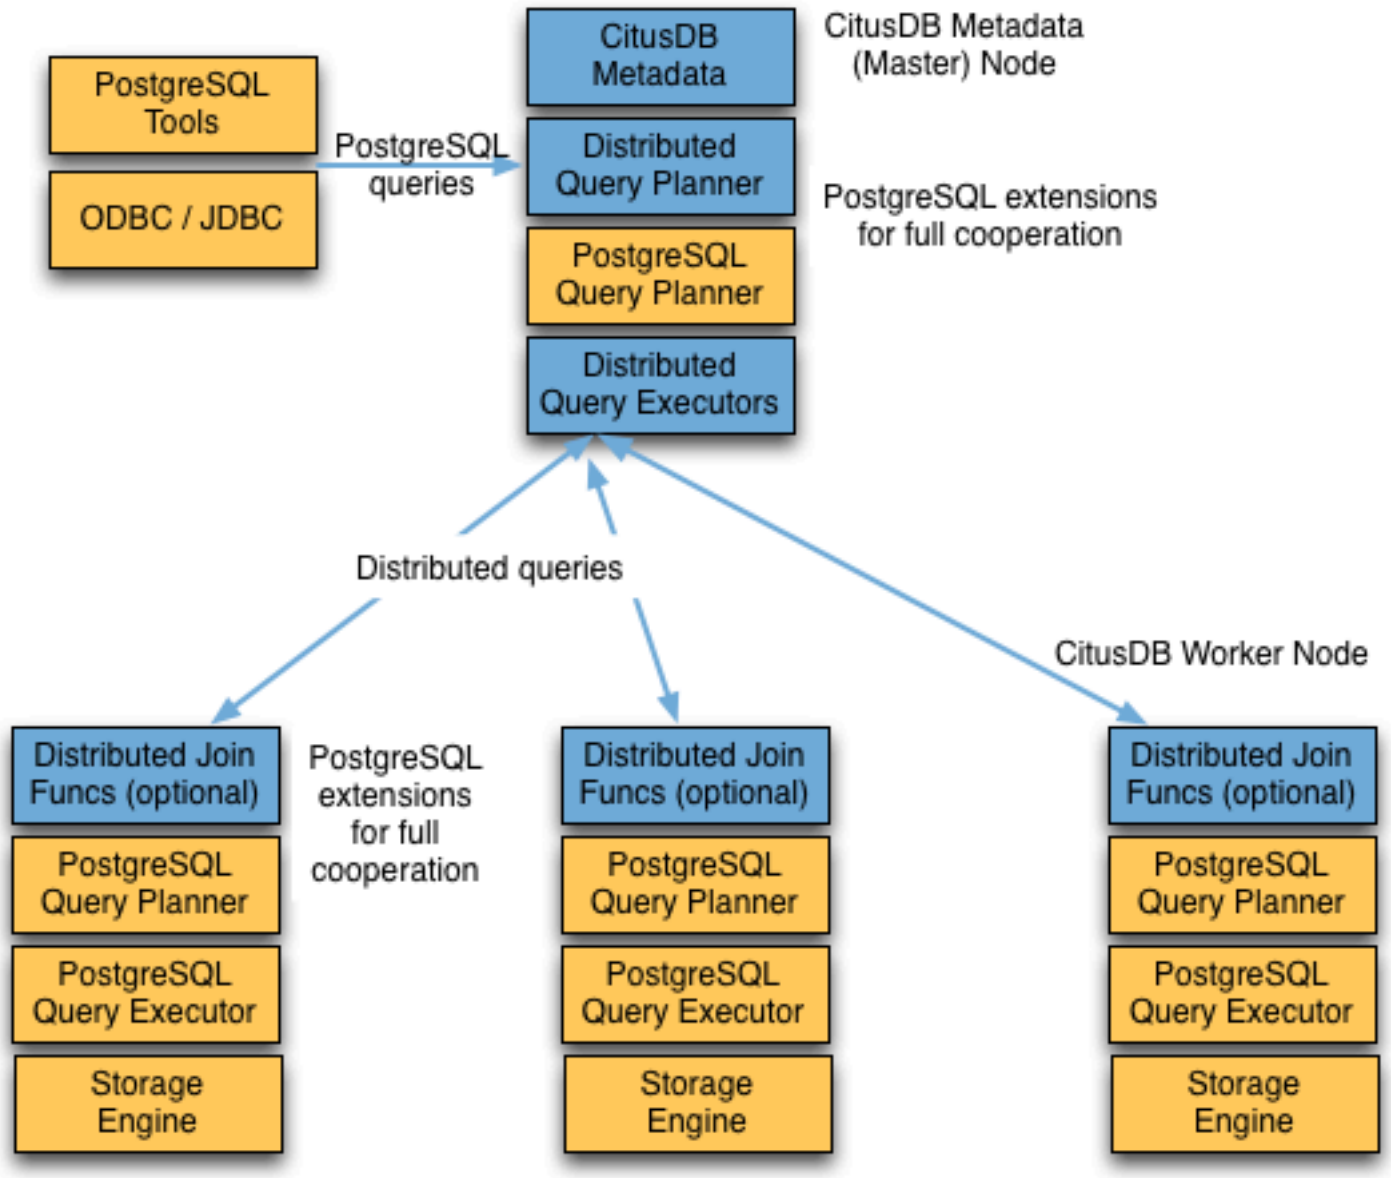
In such cases the table(s) to be partitioned are determined by the query optimizer on the basis of the distribution columns, join keys and sizes of the tables. With repartitioned tables, it can be ensured that only relevant shard pairs are joined with each other reducing the amount of data transferred across network drastically.

In general, co-located joins are more efficient than repartition joins as repartition joins require shuffling of data. So, you should try to distribute your tables by the common join keys whenever possible.

J.5.7.4.5. Query Processing

A citus cluster consists of a coordinator instance and multiple worker instances. The data is sharded on the workers while the coordinator stores metadata about these shards. All queries issued to the cluster are executed via the coordinator. The coordinator partitions the query into smaller query fragments where each query fragment can be run independently on a shard. The coordinator then assigns the query fragments to workers, oversees their execution, merges their results, and returns the final result to the user. The query processing architecture can be described in brief by the diagram below.

Figure J.16. Query Processing Architecture



citus query processing pipeline involves the two components:

- Distributed query planner and executor
- Postgres Pro planner and executor

We discuss them in greater detail in the subsequent sections.

J.5.7.4.5.1. Distributed Query Planner

citus distributed query planner takes in a SQL query and plans it for distributed execution.

For `SELECT` queries, the planner first creates a plan tree of the input query and transforms it into its commutative and associative form so it can be parallelized. It also applies several optimizations to ensure that the queries are executed in a scalable manner, and that network I/O is minimized.

Next, the planner breaks the query into two parts: the coordinator query, which runs on the coordinator, and the worker query fragments, which run on individual shards on the workers. The planner then assigns these query fragments to the workers such that all their resources are used efficiently. After this step, the distributed query plan is passed on to the distributed executor for execution.

The planning process for key-value lookups on the distribution column or modification queries is slightly different as they hit exactly one shard. Once the planner receives an incoming query, it needs to decide the correct shard to which the query should be routed. To do this, it extracts the distribution column in the incoming row and looks up the metadata to determine the right shard for the query. Then, the planner rewrites the SQL of that command to reference the shard table instead of the original table. This re-written plan is then passed to the distributed executor.

J.5.7.4.5.2. Distributed Query Executor

citus distributed executor runs distributed query plans and handles failures. The executor is well suited for getting fast responses to queries involving filters, aggregations, and co-located joins, as well as running single-tenant queries with full SQL coverage. It opens one connection per shard to the workers as needed and sends all fragment queries to them. It then fetches the results from each fragment query, merges them, and gives the final results back to the user.

Subquery/CTE Push-Pull Execution

If necessary citus can gather results from subqueries and CTEs into the coordinator node and then push them back across workers for use by an outer query. This allows citus to support a greater variety of SQL constructs.

For example, having subqueries in the `WHERE` clause sometimes cannot execute inline at the same time as the main query, but must be done separately. Suppose a web analytics application maintains a `page_views` table partitioned by `page_id`. To query the number of visitor hosts on the top twenty most visited pages, we can use a subquery to find the list of pages, then an outer query to count the hosts.

```
SELECT page_id, count(distinct host_ip)
FROM page_views
WHERE page_id IN (
  SELECT page_id
  FROM page_views
  GROUP BY page_id
  ORDER BY count(*) DESC
  LIMIT 20
)
GROUP BY page_id;
```

The executor would like to run a fragment of this query against each shard by `page_id`, counting distinct `host_ips`, and combining the results on the coordinator. However, the `LIMIT` in the subquery means the subquery cannot be executed as part of the fragment. By recursively planning the query citus can run the subquery separately, push the results to all workers, run the main fragment query, and pull the results back to the coordinator. The “push-pull” design supports subqueries like the one above.

Let's see this in action by reviewing the `EXPLAIN` output for this query. It is fairly involved:

```
GroupAggregate  (cost=0.00..0.00 rows=0 width=0)
```

```
 Group Key: remote_scan.page_id
 ->  Sort  (cost=0.00..0.00 rows=0 width=0)
   Sort Key: remote_scan.page_id
   ->  Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
     ->  Distributed Subplan 6_1
       ->  Limit  (cost=0.00..0.00 rows=0 width=0)
         ->  Sort  (cost=0.00..0.00 rows=0 width=0)
           Sort Key:
COALESCE((pg_catalog.sum((COALESCE((pg_catalog.sum(remote_scan.worker_column_2))::bigint,
'0'::bigint))))::bigint, '0'::bigint) DESC
           ->  HashAggregate  (cost=0.00..0.00 rows=0 width=0)
             Group Key: remote_scan.page_id
             ->  Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
               Task Count: 32
               Tasks Shown: One of 32
               ->  Task
                 Node: host=localhost port=9701 dbname=postgres
                 ->  HashAggregate  (cost=54.70..56.70 rows=200 width=12)
                   Group Key: page_id
                   ->  Seq Scan on page_views_102008 page_views  (cost=0.00..43.47
rows=2247 width=4)
     Task Count: 32
     Tasks Shown: One of 32
     ->  Task
       Node: host=localhost port=9701 dbname=postgres
       ->  HashAggregate  (cost=84.50..86.75 rows=225 width=36)
         Group Key: page_views.page_id, page_views.host_ip
         ->  Hash Join  (cost=17.00..78.88 rows=1124 width=36)
           Hash Cond: (page_views.page_id = intermediate_result.page_id)
           ->  Seq Scan on page_views_102008 page_views  (cost=0.00..43.47 rows=2247
width=36)
           ->  Hash  (cost=14.50..14.50 rows=200 width=4)
             ->  HashAggregate  (cost=12.50..14.50 rows=200 width=4)
               Group Key: intermediate_result.page_id
               ->  Function Scan on read_intermediate_result intermediate_result
(cost=0.00..10.00 rows=1000 width=4)
```

Let's break it apart and examine each piece.

```
GroupAggregate  (cost=0.00..0.00 rows=0 width=0)
  Group Key: remote_scan.page_id
  ->  Sort  (cost=0.00..0.00 rows=0 width=0)
    Sort Key: remote_scan.page_id
```

The root of the tree is what the coordinator node does with the results from the workers. In this case, it is grouping them, and `GroupAggregate` requires they be sorted first.

```
->  Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
  ->  Distributed Subplan 6_1
.
```

The custom scan has two large sub-trees, starting with a “distributed subplan”.

```
->  Limit  (cost=0.00..0.00 rows=0 width=0)
  ->  Sort  (cost=0.00..0.00 rows=0 width=0)
    Sort Key:
COALESCE((pg_catalog.sum((COALESCE((pg_catalog.sum(remote_scan.worker_column_2))::bigint,
'0'::bigint))))::bigint, '0'::bigint) DESC
    ->  HashAggregate  (cost=0.00..0.00 rows=0 width=0)
      Group Key: remote_scan.page_id
```

```
      ->  Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
        Task Count: 32
        Tasks Shown: One of 32
        ->  Task
          Node: host=localhost port=9701 dbname=postgres
          ->  HashAggregate  (cost=54.70..56.70 rows=200 width=12)
            Group Key: page_id
            ->  Seq Scan on page_views_102008 page_views  (cost=0.00..43.47 rows=2247
 width=4)
.
```

Worker nodes run the above for each of the thirty-two shards (citus is choosing one representative for display). We can recognize all the pieces of the `IN (…)` subquery: the sorting, grouping and limiting. When all workers have completed this query, they send their output back to the coordinator which puts it together as “intermediate results”.

```
Task Count: 32
Tasks Shown: One of 32
->  Task
  Node: host=localhost port=9701 dbname=postgres
  ->  HashAggregate  (cost=84.50..86.75 rows=225 width=36)
    Group Key: page_views.page_id, page_views.host_ip
    ->  Hash Join  (cost=17.00..78.88 rows=1124 width=36)
      Hash Cond: (page_views.page_id = intermediate_result.page_id)
.
```

The citus extension starts another executor job in this second subtree. It is going to count distinct hosts in `page_views`. It uses a `JOIN` to connect with the intermediate results. The intermediate results will help it restrict to the top twenty pages.

```
->  Seq Scan on page_views_102008 page_views  (cost=0.00..43.47 rows=2247 width=36)
->  Hash  (cost=14.50..14.50 rows=200 width=4)
  ->  HashAggregate  (cost=12.50..14.50 rows=200 width=4)
    Group Key: intermediate_result.page_id
    ->  Function Scan on read_intermediate_result intermediate_result
 (cost=0.00..10.00 rows=1000 width=4)
.
```

The worker internally retrieves intermediate results using the `read_intermediate_result` function, which loads data from a file that was copied in from the coordinator node.

This example showed how citus executed the query in multiple steps with a distributed subplan and how you can use `EXPLAIN` to learn about distributed query execution.

J.5.7.4.5.3. Postgres Pro Planner and Executor

Once the distributed executor sends the query fragments to the workers, they are processed like regular Postgres Pro queries. The Postgres Pro planner on that worker chooses the most optimal plan for executing that query locally on the corresponding shard table. The Postgres Pro executor then runs that query and returns the query results back to the distributed executor. Learn more about the Postgres Pro planner and executor. Finally, the distributed executor passes the results to the coordinator for final aggregation.

J.5.7.4.6. Manual Query Propagation

When the user issues a query, the citus coordinator partitions it into smaller query fragments where each query fragment can be run independently on a worker shard. This allows citus to distribute each query across the cluster.

However, the way queries are partitioned into fragments (and which queries are propagated at all) varies by the type of query. In some advanced situations it is useful to manually control this behavior. citus provides utility functions to propagate SQL to workers, shards, or co-located placements.

Manual query propagation bypasses coordinator logic, locking, and any other consistency checks. These functions are available as a last resort to allow statements which citus otherwise does not run natively. Use them carefully to avoid data inconsistency and deadlocks.

J.5.7.4.6.1. Running on All Workers

The least granular level of execution is broadcasting a statement for execution on all workers. This is useful for viewing properties of entire worker databases.

```
-- List the work_mem setting of each worker database
SELECT run_command_on_workers($cmd$ SHOW work_mem; $cmd$);
```

To run on all nodes, both workers and the coordinator, use the `run_command_on_all_nodes` function.

> **Note**
>
> This command should not be used to create database objects on the workers, as doing so will make it harder to add worker nodes in an automated fashion.

> **Note**
>
> The `run_command_on_workers` function and other manual propagation commands in this section can run only queries that return a single column and single row.

J.5.7.4.6.2. Running on All Shards

The next level of granularity is running a command across all shards of a particular distributed table. It can be useful, for instance, in reading the properties of a table directly on workers. Queries run locally on a worker node have full access to metadata such as table statistics.

The `run_command_on_shards` function applies an SQL command to each shard, where the shard name is provided for interpolation in the command. Here is an example of estimating the row count for a distributed table by using the pg_class table on each worker to estimate the number of rows for each shard. Notice the `%s`, which will be replaced with each shard name.

```
-- Get the estimated row count for a distributed table by summing the
-- estimated counts of rows for each shard
SELECT sum(result::bigint) AS estimated_count
  FROM run_command_on_shards(
    'my_distributed_table',
    $cmd$
      SELECT reltuples
        FROM pg_class c
        JOIN pg_catalog.pg_namespace n on n.oid=c.relnamespace
       WHERE (n.nspname || '.' || relname)::regclass = '%s'::regclass
         AND n.nspname NOT IN ('citus', 'pg_toast', 'pg_catalog')
    $cmd$
  );
```

A useful companion to `run_command_on_shards` is the `run_command_on_colocated_placements` function. It interpolates the names of *two* placements of co-located distributed tables into a query. The placement pairs are always chosen to be local to the same worker where full SQL coverage is available. Thus we can use advanced SQL features like triggers to relate the tables:

```
-- Suppose we have two distributed tables
CREATE TABLE little_vals (key int, val int);
CREATE TABLE big_vals    (key int, val int);
SELECT create_distributed_table('little_vals', 'key');
SELECT create_distributed_table('big_vals',    'key');
```

```
-- We want to synchronize them so that every time little_vals
-- are created, big_vals appear with double the value
--
-- First we make a trigger function, which will
-- take the destination table placement as an argument
CREATE OR REPLACE FUNCTION embiggen() RETURNS TRIGGER AS $$
  BEGIN
    IF (TG_OP = 'INSERT') THEN
      EXECUTE format(
        'INSERT INTO %s (key, val) SELECT ($1).key, ($1).val*2;',
        TG_ARGV[0]
      ) USING NEW;
    END IF;
    RETURN NULL;
  END;
$$ LANGUAGE plpgsql;

-- Next we relate the co-located tables by the trigger function
-- on each co-located placement
SELECT run_command_on_colocated_placements(
  'little_vals',
  'big_vals',
  $cmd$
    CREATE TRIGGER after_insert AFTER INSERT ON %s
      FOR EACH ROW EXECUTE PROCEDURE embiggen(%L)
  $cmd$
);
```

J.5.7.4.6.3. Limitations

- There are no safeguards against deadlock for multi-statement transactions.
- There are no safeguards against mid-query failures and resulting inconsistencies.
- Query results are cached in memory; these functions cannot deal with very big result sets.
- The functions error out early if they cannot connect to a node.

J.5.7.4.7. SQL Support and Workarounds

As citus provides distributed functionality by extending Postgres Pro, it is compatible with Postgres Pro constructs. This means that users can use the tools and features that come with the rich and extensible Postgres Pro ecosystem for distributed tables created with citus.

citus has 100% SQL coverage for any queries it is able to execute on a single worker node. These kind of queries are common in multi-tenant applications when accessing information about a single tenant.

Even cross-node queries (used for parallel computations) support most SQL features. However, some SQL features are not supported for queries, which combine information from multiple nodes.

J.5.7.4.7.1. Limitations

General

These limitations apply to all models of operation:

- The rule system is not supported.
- Subqueries within `INSERT` queries are not supported.
- Distributing multi-level partitioned tables is not supported.
- Functions used in `UPDATE` queries on distributed tables must not be `VOLATILE`.
- `STABLE` functions used in `UPDATE` queries cannot be called with column references.

- Modifying views when the query contains citus tables is not supported.

citus encodes the node identifier in the sequence generated on every node, this allows every individual node to take inserts directly without having the sequence overlap. This method however does not work for sequences that are smaller than `bigint`, which may result in inserts on worker nodes failing, in that case you need to drop the column and add a `bigint` based one, or route the inserts via the coordinator.

Cross-Node SQL Queries

- `SELECT … FOR UPDATE` work in single-shard queries only.
- TABLESAMPLE work in single-shard queries only.
- Correlated subqueries are supported only when the correlation is on the distribution column.
- Outer joins between distributed tables are only supported on the distribution column.
- Recursive CTEs work in single-shard queries only.
- Grouping sets work in single-shard queries only.
- Only regular, foreign or partitioned tables can be distributed.
- The SQL `MERGE` command is supported in the following combinations of table types:

Target	Source	Support	Comments
Local	Local	Yes	
Local	Reference	Yes	
Local	Distributed	No	Feature in development
Distributed	Local	Yes	
Distributed	Distributed	Yes	Including non co-located tables
Distributed	Reference	Yes	
Reference	N/A	No	Reference table as target is not allowed

For a detailed reference of the Postgres Pro SQL command dialect (which can be used as is by citus users), you can see the SQL Commands section.

Schema-Based Sharding SQL Compatibility

When using schema-based sharding the following features are not available:

- Foreign keys across distributed schemas are not supported.
- Joins across distributed schemas are subject to cross-node SQL queries limitations.
- Creating a distributed schema and tables in a single SQL statement is not supported.

J.5.7.4.7.2. Workarounds

Before attempting workarounds consider whether citus is appropriate for your situation. The citus extension works well for real-time analytics and multi-tenant use cases.

citus supports all SQL statements in the multi-tenant use case. Even in the real-time analytics use cases, with queries that span across nodes, citus supports the majority of statements. The few types of unsupported queries are listed in the Are there any Postgres Pro features not supported by citus? section. Many of the unsupported features have workarounds; below are a number of the most useful.

Work Around Limitations Using CTEs

When a SQL query is unsupported, one way to work around it is using CTEs, which use what we call pull-push execution.

```
SELECT * FROM dist WHERE EXISTS (SELECT 1 FROM local WHERE local.a = dist.a);
```

```
/*
ERROR:  direct joins between distributed and local tables are not supported
HINT:  Use CTEs or subqueries to select from local tables and use them in joins
*/
```

To work around this limitation, you can turn the query into a router query by wrapping the distributed part in a CTE.

```
WITH cte AS (SELECT * FROM dist)
SELECT * FROM cte WHERE EXISTS (SELECT 1 FROM local WHERE local.a = cte.a);
```

Remember that the coordinator will send the results of the CTE to all workers which require it for processing. Thus it is best to either add the most specific filters and limits to the inner query as possible, or else aggregate the table. That reduces the network overhead which such a query can cause. More about this in the Subquery/CTE Network Overhead section.

Temp Tables: the Workaround of Last Resort

There are still a few queries that are unsupported even with the use of push-pull execution via subqueries. One of them is using grouping sets on a distributed table.

In our real-time analytics tutorial we created a table called `github_events`, distributed by the column `user_id`. Let's query it and find the earliest events for a preselected set of repos, grouped by combinations of event type and event publicity. A convenient way to do this is with grouping sets. However, as mentioned, this feature is not yet supported in distributed queries:

```
-- This will not work

  SELECT repo_id, event_type, event_public,
         grouping(event_type, event_public),
         min(created_at)
    FROM github_events
   WHERE repo_id IN (8514, 15435, 19438, 21692)
GROUP BY repo_id, ROLLUP(event_type, event_public);
```

```
ERROR:  could not run distributed query with GROUPING
HINT:  Consider using an equality filter on the distributed table's partition column.
```

There is a trick, though. We can pull the relevant information to the coordinator as a temporary table:

```
-- Grab the data, minus the aggregate, into a local table

CREATE TEMP TABLE results AS (
  SELECT repo_id, event_type, event_public, created_at
    FROM github_events
       WHERE repo_id IN (8514, 15435, 19438, 21692)
    );

-- Now run the aggregate locally

  SELECT repo_id, event_type, event_public,
         grouping(event_type, event_public),
         min(created_at)
    FROM results
GROUP BY repo_id, ROLLUP(event_type, event_public);
```

```
 repo_id |    event_type     | event_public | grouping |         min
---------+-------------------+--------------+----------+---------------------
    8514 | PullRequestEvent  | t            |        0 | 2016-12-01 05:32:54
    8514 | IssueCommentEvent | t            |        0 | 2016-12-01 05:32:57
   19438 | IssueCommentEvent | t            |        0 | 2016-12-01 05:48:56
   21692 | WatchEvent        | t            |        0 | 2016-12-01 06:01:23
```

```
   15435 | WatchEvent        | t            |        0 | 2016-12-01 05:40:24
   21692 | WatchEvent        |              |        1 | 2016-12-01 06:01:23
   15435 | WatchEvent        |              |        1 | 2016-12-01 05:40:24
    8514 | PullRequestEvent  |              |        1 | 2016-12-01 05:32:54
    8514 | IssueCommentEvent |              |        1 | 2016-12-01 05:32:57
   19438 | IssueCommentEvent |              |        1 | 2016-12-01 05:48:56
   15435 |                   |              |        3 | 2016-12-01 05:40:24
   21692 |                   |              |        3 | 2016-12-01 06:01:23
   19438 |                   |              |        3 | 2016-12-01 05:48:56
    8514 |                   |              |        3 | 2016-12-01 05:32:54
```

Creating a temporary table on the coordinator is a last resort. It is limited by the disk size and CPU of the node.

Subqueries Within `INSERT` Queries

Try rewriting your queries with `INSERT INTO ... SELECT` syntax.

The following SQL:

```
INSERT INTO a.widgets (map_id, widget_name)
VALUES (
    (SELECT mt.map_id FROM a.map_tags mt WHERE mt.map_license = '12345'),
    'Test'
);
```

Would become:

```
INSERT INTO a.widgets (map_id, widget_name)
SELECT mt.map_id, 'Test'
  FROM a.map_tags mt
 WHERE mt.map_license = '12345';
```

J.5.7.5. citus API

J.5.7.5.1. citus Utility Functions

This section contains reference information for the user defined functions provided by citus. These functions help in providing additional distributed functionality to citus other than the standard SQL commands.

J.5.7.5.1.1. Table and Shard DDL

`citus_schema_distribute (schemaname regnamespace) returns void`

Converts existing regular schemas into distributed schemas, which are automatically associated with individual co-location groups such that the tables created in those schemas will be automatically converted to co-located distributed tables without a shard key. The process of distributing the schema will automatically assign and move it to an existing node in the cluster.

Arguments:

- *`schemaname`* — the name of the schema, which needs to be distributed.

The example below shows how to distribute three schemas named `tenant_a`, `tenant_b`, and `tenant_c`. For more examples, see the Microservices section:

```
SELECT citus_schema_distribute('tenant_a');
SELECT citus_schema_distribute('tenant_b');
SELECT citus_schema_distribute('tenant_c');
```

`citus_schema_undistribute (schemaname regnamespace) returns void`

Converts an existing distributed schema back into a regular schema. The process results in the tables and data being moved from the current node back to the coordinator node in the cluster.

Arguments:

- *schemaname* — the name of the schema, which needs to be distributed.

The example below shows how to convert three different distributed schemas back into regular schemas. For more examples, see the Microservices section:

```
SELECT citus_schema_undistribute('tenant_a');
SELECT citus_schema_undistribute('tenant_b');
SELECT citus_schema_undistribute('tenant_c');
```

`create_distributed_table (table_name regclass, distribution_column text, distribution_type citus.distribution_type, colocate_with text, shard_count int) returns void`

Defines a distributed table and create its shards if it is a hash-distributed table. This function takes in a table name, the distribution column, and an optional distribution method and inserts appropriate metadata to mark the table as distributed. The function defaults to hash distribution if no distribution method is specified. If the table is hash-distributed, the function also creates worker shards based on the shard count configuration value. If the table contains any rows, they are automatically distributed to worker nodes.

Arguments:

- *table_name* — the name of the table, which needs to be distributed.
- *distribution_column* — the column on which the table is to be distributed.
- *distribution_type* — an optional distribution method. The default value is `hash`.
- *colocate_with* — include current table in the co-location group of another table. This is an optional argument. By default tables are co-located when they are distributed by columns of the same type with the same shard count. If you want to break this co-location later, you can use the update_distributed_table_colocation function. Possible values for this argument are `default`, which is the default value, `none` to start a new co-location group, or the name of another table to co-locate with the table. To learn more, see the Co-Locating Tables section.

  Keep in mind that the default value of the *colocate_with* argument does implicit co-location. As explained in the Table Co-Location section, this can be a great thing when tables are related or will be joined. However, when two tables are unrelated but happen to use the same datatype for their distribution columns, accidentally co-locating them can decrease performance during shard rebalancing. The table shards will be moved together unnecessarily in a “cascade”. If you want to break this implicit co-location, you can use the update_distributed_table_colocation function.

  If a new distributed table is not related to other tables, it is best to specify `colocate_with => 'none'`.
- *shard_count* — the number of shards to create for the new distributed table. This is an optional argument. When specifying *shard_count* you cannot specify a value of *colocate_with* other than `none`. To change the shard count of an existing table or co-location group, use the alter_distributed_table function.

  Allowed values for the *shard_count* argument are between `1` and `64000`. For guidance on choosing the optimal value, see the Shard Count section.

This example informs the database that the `github_events` table should be distributed by hash on the `repo_id` column. For more examples, see the Creating and Modifying Distributed Objects (DDL) section:

```
SELECT create_distributed_table('github_events', 'repo_id');

-- Alternatively, to be more explicit:
SELECT create_distributed_table('github_events', 'repo_id',
                                colocate_with => 'github_repo');
```

`truncate_local_data_after_distributing_table (function_name regclass) returns void`

Truncates all local rows after distributing a table and prevent constraints from failing due to outdated local records. The truncation cascades to tables having a foreign key to the designated table. If the referring tables are not themselves distributed, then truncation is forbidden until they are to protect referential integrity:

```
ERROR:  cannot truncate a table referenced in a foreign key constraint by a local
 table
```

Truncating local coordinator node table data is safe for distributed tables because their rows, if they have any, are copied to worker nodes during distribution.

Arguments:

- *`table_name`* — the name of the distributed table whose local counterpart on the coordinator node should be truncated.

The example below shows how to use the function:

```
-- Requires that argument is a distributed table
SELECT truncate_local_data_after_distributing_table('public.github_events');
```

`undistribute_table (table_name regclass, cascade_via_foreign_keys boolean) returns void`

Undoes the action of the create_distributed_table or create_reference_table functions. Undistributing moves all data from shards back into a local table on the coordinator node (assuming the data can fit), then deletes the shards.

citus will not undistribute tables that have, or are referenced by, foreign keys, unless the *`cascade_via_foreign_keys`* argument is set to `true`. If this argument is `false` (or omitted), then you must manually drop the offending foreign key constraints before undistributing.

Arguments:

- *`table_name`* — the name of the distributed or reference table to undistribute.
- *`cascade_via_foreign_keys`* — when this optional argument is set to `true`, the function also undistributes all tables that are related to *`table_name`* through foreign keys. Use caution with this argument because it can potentially affect many tables. The default value is `false`.

The example below shows how to distribute the `github_events` table and then undistribute it:

```
-- First distribute the table
SELECT create_distributed_table('github_events', 'repo_id');

-- Undo that and make it local again
SELECT undistribute_table('github_events');
```

`alter_distributed_table (table_name regclass, distribution_column text, shard_count int, colocate_with text, cascade_to_colocated boolean) returns void`

Changes the distribution column, shard count or co-location properties of a distributed table.

Arguments:

- *`table_name`* — the name of the distributed table, which will be altered.
- *`distribution_column`* — the name of the new distribution column. The default value of this optional argument is `NULL`.
- *`shard_count`* — the new shard count. The default value of this optional argument is `NULL`.
- *`colocate_with`* — the table that the current distributed table will be co-located with. Possible values are `default`, `none` to start a new co-location group, or the name of another table with which to co-locate. The default value of this optional argument is `default`.

- *cascade_to_colocated*. When this argument is set to `true`, *shard_count* and *colocate_with* changes will also be applied to all of the tables that were previously co-located with the table, and the co-location will be preserved. If it is `false`, the current co-location of this table will be broken. The default value of this optional argument is `false`.

The example below shows how to use the function:

```
-- Change distribution column
SELECT alter_distributed_table('github_events', distribution_column:='event_id');

-- Change shard count of all tables in colocation group
SELECT alter_distributed_table('github_events', shard_count:=6,
 cascade_to_colocated:=true);

-- Change colocation
SELECT alter_distributed_table('github_events', colocate_with:='another_table');
```

`alter_table_set_access_method (table_name regclass, access_method text) returns void`

Changes access method of a table (e.g. `heap` or columnar).

Arguments:

- *table_name* — the name of the table whose access method will change.
- *access_method* — the name of the new access method.

The example below shows how to use the function:

```
SELECT alter_table_set_access_method('github_events', 'columnar');
```

`remove_local_tables_from_metadata () returns void`

Removes local tables from metadata of the citus extension that no longer need to be there. (See the citus.enable_local_reference_table_foreign_keys configuration parameter.)

Usually if a local table is in citus metadata, there is a reason, such as the existence of foreign keys between the table and a reference table. However, if `citus.enable_local_reference_table_foreign_keys` is disabled, citus will no longer manage metadata in that situation, and unnecessary metadata can persist until manually cleaned.

`create_reference_table (table_name regclass) returns void`

Defines a small reference or dimension table. This function takes in a table name, and creates a distributed table with just one shard, replicated to every worker node.

Arguments:

- *table_name* — the name of the small dimension or reference table, which needs to be distributed.

The example below informs the database that the `nation` table should be defined as a reference table:

```
SELECT create_reference_table('nation');
```

`citus_add_local_table_to_metadata (table_name regclass, cascade_via_foreign_keys boolean) returns void`

Adds a local Postgres Pro table into citus metadata. A major use case for this function is to make local tables on the coordinator accessible from any node in the cluster. This is mostly useful when running queries from other nodes. The data associated with the local table stays on the coordinator, only its schema and metadata are sent to the workers.

Note that adding local tables to the metadata comes at a slight cost. When you add the table, citus must track it in the pg_dist_partition. Local tables that are added to metadata inherit the same

limitations as reference tables (see the Creating and Modifying Distributed Objects (DDL) and SQL Support and Workarounds sections).

If you use the undistribute_table function, citus will automatically remove the resulting local tables from metadata, which eliminates such limitations on those tables.

Arguments:

- *table_name* — the name of the table on the coordinator to be added to citus metadata.
- *cascade_via_foreign_keys* — when this optional argument is set to `true`, the function adds other tables that are in a foreign key relationship with given table into metadata automatically. Use caution with this argument, because it can potentially affect many tables. The default value is `false`.

The example below informs the database that the `nation` table should be defined as a coordinator-local table, accessible from any node:

```
SELECT citus_add_local_table_to_metadata('nation');
```

`update_distributed_table_colocation (table_name regclass, colocate_with text) returns void`

Updates co-location of a distributed table. This function can also be used to break co-location of a distributed table. citus will implicitly co-locate two tables if the distribution column is the same type, this can be useful if the tables are related and will do some joins. If table `A` and `B` are co-located and table `A` gets rebalanced, table `B` will also be rebalanced. If table `B` does not have a replica identity, the rebalance will fail. Therefore, this function can be useful breaking the implicit co-location in that case. Note that this function does not move any data around physically.

Arguments:

- *table_name* — the name of the table co-location of which will be updated.
- *colocate_with* — the table with which the table should be co-located.

If you want to break the co-location of a table, specify `colocate_with => 'none'`.

The example below shows that co-location of table `A` is updated as co-location of table `B`:

```
SELECT update_distributed_table_colocation('A', colocate_with => 'B');
```

Assume that table `A` and table `B` are co-located (possibily implicitly). If you want to break the co-location, do the following:

```
SELECT update_distributed_table_colocation('A', colocate_with => 'none');
```

Now, assume that tables `A`, `B`, `C`, and `D` are co-located and you want to co-locate table `A` with `B` and table `C` with table `D`:

```
SELECT update_distributed_table_colocation('C', colocate_with => 'none');
SELECT update_distributed_table_colocation('D', colocate_with => 'C');
```

If you have a hash-distributed table named `none` and you want to update its co-location, you can do:

```
SELECT update_distributed_table_colocation('"none"', colocate_with =>
  'some_other_hash_distributed_table');
```

`create_distributed_function (function_name regprocedure, distribution_arg_name text, colocate_with text, force_delegation bool) returns void`

Propagates a function from the coordinator node to workers and marks it for distributed execution. When a distributed function is called on the coordinator, citus uses the value of the *distribution_arg_name* argument to pick a worker node to run the function. Calling the function on workers increases parallelism and can bring the code closer to data in shards for lower latency.

Note that the Postgres Pro search path is not propagated from the coordinator to workers during distributed function execution, so distributed function code should fully qualify the names of database objects. Also notices emitted by the functions will not be displayed to the user.

Arguments:

- *function_name* — the name of the function to be distributed. The name must include the function parameter types in parentheses because multiple functions can have the same name in Postgres Pro. For instance, `'foo(int)'` is different from `'foo(int, text)'`.
- *distribution_arg_name* — the argument name by which to distribute. For convenience (or if the function arguments do not have names), a positional placeholder is allowed, such as `'$1'`. If this argument is not specified, then the function named by *function_name* is merely created on the workers. If worker nodes are added in the future, the function will automatically be created there too. This is an optional argument.
- *colocate_with* — when the distributed function reads or writes to a distributed table (or more generally co-locating tables), be sure to name that table using the this argument. This ensures that each invocation of the function runs on the worker node containing relevant shards. This is an optional argument.
- *force_delegation*. The default value is `NULL`.

The example below shows how to use the function:

```
-- An example function that updates a hypothetical
-- event_responses table, which itself is distributed by event_id
CREATE OR REPLACE FUNCTION
  register_for_event(p_event_id int, p_user_id int)
RETURNS void LANGUAGE plpgsql AS $fn$
BEGIN
  INSERT INTO event_responses VALUES ($1, $2, 'yes')
  ON CONFLICT (event_id, user_id)
  DO UPDATE SET response = EXCLUDED.response;
END;
$fn$;

-- Distribute the function to workers, using the p_event_id argument
-- to determine which shard each invocation affects, and explicitly
-- colocating with event_responses which the function updates
SELECT create_distributed_function(
  'register_for_event(int, int)', 'p_event_id',
  colocate_with := 'event_responses'
);
```

```
alter_columnar_table_set (table_name regclass, chunk_group_row_limit int,
stripe_row_limit int, compression name, compression_level int) returns void
```

Changes settings on a columnar table. Calling this function on a non-columnar table gives an error. All arguments except the *table_name* are optional.

To view current options for all columnar tables, consult this table:

```
SELECT * FROM columnar.options;
```

The default values for columnar settings for newly created tables can be overridden with these configuration parameters:

- `columnar.compression`
- `columnar.compression_level`
- `columnar.stripe_row_count`
- `columnar.chunk_row_count`

Arguments:

- *table_name* — the name of the columnar table.
- *chunk_row_count* — the maximum number of rows per chunk for newly inserted data. Existing chunks of data will not be changed and may have more rows than this maximum value. The default value is `10000`.
- *stripe_row_count* — the maximum number of rows per stripe for newly inserted data. Existing stripes of data will not be changed and may have more rows than this maximum value. The default value is `150000`.
- *compression* — the compression type for the newly inserted data. Existing data will not be recompressed or decompressed. The default and generally suggested value is `zstd` (if support has been compiled in). Allowed values are `none`, `pglz`, `zstd`, `lz4`, and `lz4hc`.
- *compression_level*. Allowed values are from 1 to 19. If the compression method does not support the level chosen, the closest level will be selected instead.

The example below shows how to use the function:

```
SELECT alter_columnar_table_set(
  'my_columnar_table',
  compression => 'none',
  stripe_row_count => 10000);
```

`create_time_partitions (table_name regclass, partition_interval interval, end_at timestamptz, start_from timestamptz) returns boolean`

Creates partitions of a given interval to cover a given range of time. Returns `true` if new partitions are created and `false` if they already exist.

Arguments:

- *table_name* — the table for which to create new partitions. The table must be partitioned on one column of type `date`, `timestamp`, or `timestamptz`.
- *partition_interval* — the interval of time, such as `'2 hours'`, or `'1 month'`, to use when setting ranges on new partitions.
- *end_at* — create partitions up to this time. The last partition will contain the point `end_at` and no later partitions will be created.
- *start_from* — pick the first partition so that it contains the point `start_from`. The default value is `now()`.

The example below shows how to use the function:

```
-- Create a year's worth of monthly partitions
-- in table foo, starting from the current time

SELECT create_time_partitions(
  table_name         := 'foo',
  partition_interval := '1 month',
  end_at             := now() + '12 months'
);
```

`drop_old_time_partitions (table_name regclass, older_than timestamptz)`

Removes all partitions whose intervals fall before a given timestamp. In addition to using this function, you might consider the alter_old_partitions_set_access_method function to compress the old partitions with columnar storage.

Arguments:

- *table_name* — the table for which to remove partitions. The table must be partitioned on one column of type `date`, `timestamp`, or `timestamptz`.
- *older_than* — drop partitions whose upper limit is less than or equal to the `older_than` value.

The example below shows how to use the procedure:

```
-- Drop partitions that are over a year old

CALL drop_old_time_partitions('foo', now() - interval '12 months');
```

`alter_old_partitions_set_access_method (parent_table_name regclass, older_than timestamptz, new_access_method name)`

In the timeseries data use case tables are often partitioned by time and old partitions are compressed into read-only columnar storage.

Arguments:

- *`parent_table_name`* — the table for which to change partitions. The table must be partitioned on one column of type `date`, `timestamp`, or `timestamptz`.
- *`older_than`* — change partitions whose upper limit is less than or equal to the `older_than` value.
- *`new_access_method`*. Allowed values are `heap` for row-based storage or `columnar` for columnar storage.

The example below shows how to use the procedure:

```
CALL alter_old_partitions_set_access_method(
  'foo', now() - interval '6 months',
  'columnar'
);
```

J.5.7.5.1.2. Metadata / Configuration Information

`citus_add_node (nodename text, nodeport integer, groupid integer, noderole noderole, nodecluster name) returns integer`

> **Note**
>
> This function requires database superuser access to run.

Registers a new node addition in the cluster in the citus metadata table pg_dist_node. It also copies reference tables to the new node. The function returns the `nodeid` column from the newly inserted row in `pg_dist_node`.

If you call the function on a single-node cluster, be sure to call the citus_set_coordinator_host function first.

Arguments:

- *`nodename`* — the DNS name or IP address of the new node to be added.
- *`nodeport`* — the port on which Postgres Pro is listening on the worker node.
- *`groupid`* — the group of one primary server and its secondary servers, relevant only for streaming replication. Be sure to set this argument to a value greater than zero, since zero is reserved for the coordinator node. The default value is `-1`.
- *`noderole`* — the role of the node. Allowed values are `primary` and `secondary`. The default value is `primary`.
- *`nodecluster`* — the name of the cluster. The default value is `default`.

The example below shows how to use the function:

```
SELECT * FROM citus_add_node('new-node', 12345);
 citus_add_node
----------------
              7
(1 row)
```

```
citus_update_node (node_id int, new_node_name text, new_node_port int, force bool,
lock_cooldown int) returns void
```

> **Note**
>
> This function requires database superuser access to run.

Changes the hostname and port for a node registered in the citus metadata table pg_dist_node.

Arguments:

- *node_id* — the node ID from the `pg_dist_node` table.
- *new_node_name* — the updated DNS name or IP address for the node.
- *new_node_port* — the updated port on which Postgres Pro is listening on the worker node.
- *force*. The default value is `false`.
- *lock_cooldown*. The default value is `10000`.

The example below shows how to use the function:

```
SELECT * FROM citus_update_node(123, 'new-address', 5432);
```

```
citus_set_node_property (nodename text, nodeport integer, property text, value boolean)
returns void
```

Changes properties in the citus metadata table pg_dist_node. Currently it can change only the `shouldhaveshards` property.

Arguments:

- *nodename* — the DNS name or IP address for the node.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.
- *property* — the column to change in `pg_dist_node`, currently only the `shouldhaveshard` property is supported.
- *value* — the new value for the column.

The example below shows how to use the function:

```
SELECT * FROM citus_set_node_property('localhost', 5433, 'shouldhaveshards', false);
```

```
citus_add_inactive_node (nodename text, nodeport integer, groupid integer, noderole node-
role, nodecluster name) returns integer
```

> **Note**
>
> This function requires database superuser access to run.

Similarly to the citus_add_node function, registers a new node in pg_dist_node. However, it marks the new node as inactive, meaning no shards will be placed there. Also it does *not* copy reference tables to the new node. The function returns the `nodeid` column from the newly inserted row in `pg_dist_node`.

Arguments:

- *nodename* — the DNS name or IP address of the new node to be added.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.
- *groupid* — the group of one primary server and zero or more secondary servers, relevant only for streaming replication. The default is `-1`.
- *noderole* — the role of the node. Allowed values are `primary` and `secondary`. The default value is `primary`.
- *nodecluster* — the name of the cluster. The default value is `default`.

The example below shows how to use the function:

```
SELECT * FROM citus_add_inactive_node('new-node', 12345);
 citus_add_inactive_node
--------------------------
                        7
(1 row)
```

```
citus_activate_node (nodename text, nodeport integer) returns integer
```

> **Note**
>
> This function requires database superuser access to run.

Marks a node as active in the citus metadata table pg_dist_node and copies reference tables to the node. Useful for nodes added via citus_add_inactive_node. The function returns the `nodeid` column from the newly inserted row in `pg_dist_node`.

Arguments:

- *`nodename`* — the DNS name or IP address of the new node to be added.
- *`nodeport`* — the port on which Postgres Pro is listening on the worker node.

The example below shows how to use the function:

```
SELECT * FROM citus_activate_node('new-node', 12345);
 citus_activate_node
----------------------
                     7
(1 row)
```

```
citus_disable_node (nodename text, nodeport integer, synchronous bool) returns void
```

> **Note**
>
> This function requires database superuser access to run.

This function is the opposite from citus_activate_node. It marks a node as inactive in the citus metadata table pg_dist_node, removing it from the cluster temporarily. The function also deletes all reference table placements from the disabled node. To reactivate the node, just call citus_activate_node again.

Arguments:

- *`nodename`* — the DNS name or IP address of the node to be disabled.
- *`nodeport`* — the port on which Postgres Pro is listening on the worker node.
- *`synchronous`*. The default value is `false`.

The example below shows how to use the function:

```
SELECT * FROM citus_disable_node('new-node', 12345);
```

```
citus_add_secondary_node (nodename text, nodeport integer, primaryname text, primaryport
integer, nodecluster name) returns integer
```

> **Note**
>
> This function requires database superuser access to run.

Registers a new secondary node in the cluster for an existing primary node. The function updates the citus pg_dist_node metadata table. The function returns the `nodeid` column for the secondary node from the inserted row in `pg_dist_node`.

Arguments:

- *`nodename`* — the DNS name or IP address of the new node to be added.
- *`nodeport`* — the port on which Postgres Pro is listening on the worker node.
- *`primaryname`* — the DNS name or IP address of the primary node for this secondary.
- *`primaryport`* — the port on which Postgres Pro is listening on the primary node.
- *`nodecluster`* — the name of the cluster. The default value is `default`.

The example below shows how to use the function:

```
SELECT * FROM citus_add_secondary_node('new-node', 12345, 'primary-node', 12345);
 citus_add_secondary_node
--------------------------
                        7
(1 row)
```

```
citus_remove_node (nodename text, nodeport integer) returns void
```

> **Note**
>
> This function requires database superuser access to run.

Removes the specified node from the pg_dist_node metadata table. This function will error out if there are existing shard placements on this node. Thus, before using this function, the shards will need to be moved off that node.

Arguments:

- *`nodename`* — the DNS name of the node to be removed.
- *`nodeport`* — the port on which Postgres Pro is listening on the worker node.

The example below shows how to use the function:

```
SELECT citus_remove_node('new-node', 12345);
 citus_remove_node
--------------------

(1 row)
```

```
citus_get_active_worker_nodes () returns setof record
```

Returns active worker host names and port numbers as a list of tuples where each tuple contains the following information:

- *`node_name`* — the DNS name of the worker node.
- *`node_port`* — the port on the worker node on which the database server is listening.

The example below shows the output of the function:

```
SELECT * FROM citus_get_active_worker_nodes();
 node_name | node_port
-----------+-----------
 localhost |      9700
 localhost |      9702
 localhost |      9701

(3 rows)
```

`citus_backend_gpid () returns bigint`

Returns the global process identifier (GPID) for the Postgres Pro backend serving the current session. The GPID value encodes both a node in the citus cluster and the operating system process ID of Postgres Pro on that node. The GPID is returned in the following form: (node ID * 10,000,000,000) + process ID.

citus extends the Postgres Pro server signaling functions `pg_cancel_backend` and `pg_terminate_backend` so that they accept GPIDs. In citus, calling these functions on one node can affect a backend running on another node.

The example below shows the output of the function:

```
SELECT citus_backend_gpid();
```

```
citus_backend_gpid
--------------------
       10000002055
```

`citus_check_cluster_node_health () returns setof record`

Checks connectivity between all nodes. If there are N nodes, this function checks all N^2 connections between them. The function returns the list of tuples where each tuple contains the following information:

- *`from_nodename`* — the DNS name of the source worker node.
- *`from_nodeport`* — the port on the source worker node on which the database server is listening.
- *`to_nodename`* — the DNS name of the destination worker node.
- *`to_nodeport`* — the port on the destination worker node on which the database server is listening.
- *`result`* — whether a connection could be established.

The example below shows the output of the function:

```
SELECT * FROM citus_check_cluster_node_health();
```

```
from_nodename | from_nodeport | to_nodename | to_nodeport | result
--------------+---------------+-------------+-------------+--------
localhost     |          1400 | localhost   |        1400 | t
localhost     |          1400 | localhost   |        1401 | t
localhost     |          1400 | localhost   |        1402 | t
localhost     |          1401 | localhost   |        1400 | t
localhost     |          1401 | localhost   |        1401 | t
localhost     |          1401 | localhost   |        1402 | t
localhost     |          1402 | localhost   |        1400 | t
localhost     |          1402 | localhost   |        1401 | t
localhost     |          1402 | localhost   |        1402 | t

(9 rows)
```

`citus_set_coordinator_host (host text, port integer, node_role noderole, node_cluster name) returns void`

This function is required when adding worker nodes to a citus cluster, which was created initially as a single-node cluster. When the coordinator registers a new worker, it adds a coordinator hostname from the value of the citus.local_hostname configuration parameter, which is `localhost` by default. The worker would attempt to connect to `localhost` to talk to the coordinator, which is obviously wrong.

Thus, the system administrator should call this function before calling the citus_add_node function in a single-node cluster.

Arguments:

- *host* — the DNS name of the coordinator node.
- *port* — the port on which the coordinator lists for Postgres Pro connections. The default value of this optional argument is current_setting('port').
- *node_role* — the role of the node. The default value of this optional argument is primary.
- *node_cluster* — the name of the cluster. The default value of this optional argument is default.

The example below shows how to use the function:

```
-- Assuming we are in a single-node cluster

-- First establish how workers should reach us
SELECT citus_set_coordinator_host('coord.example.com', 5432);

-- Then add a worker
SELECT * FROM citus_add_node('worker1.example.com', 5432);
```

get_shard_id_for_distribution_column (table_name regclass, distribution_value "any") returns bigint

citus assigns every row of a distributed table to a shard based on the value of the row's distribution column and the table's method of distribution. In most cases the precise mapping is a low-level detail that the database administrator can ignore. However, it can be useful to determine a row's shard either for manual database maintenance tasks or just to satisfy curiosity. The get_shard_id_for_distribution_column function provides this info for hash-distributed tables as well as reference tables and returns the shard ID that citus associates with the distribution column value for the given table.

Arguments:

- *table_name* — the name of the distributed table.
- *distribution_value* — the value of the distribution column. The default value is NULL.

The example below shows how to use the function:

```
SELECT get_shard_id_for_distribution_column('my_table', 4);

 get_shard_id_for_distribution_column
--------------------------------------
                               540007
(1 row)
```

column_to_column_name (table_name regclass, column_var_text text) returns text

Translates the partkey column of the pg_dist_partition table into a textual column name. This is useful to determine the distribution column of a distributed table. The function returns the distribution column name of the *table_name* table. To learn more, see the Finding the Distribution Column For a Table section.

Arguments:

- *table_name* — name of the distributed table.
- *column_var_text* — value of partkey column in the pg_dist_partition table.

The example below shows how to use the function:

```
-- Get distribution column name for products table

SELECT column_to_column_name(logicalrelid, partkey) AS dist_col_name
  FROM pg_dist_partition
 WHERE logicalrelid='products'::regclass;

┌──────────────┐
│ dist_col_name │
```

```
├──────────────────┤
│ company_id       │
└──────────────────┘
```

`citus_relation_size (logicalrelid regclass) returns bigint`

Returns the disk space used by all the shards of the specified distributed table. This includes the size of the “main fork” but excludes the visibility map and free space map for the shards.

Arguments:

- *`logicalrelid`* — the name of the distributed table.

The example below shows how to use the function:

```
SELECT pg_size_pretty(citus_relation_size('github_events'));
```

```
pg_size_pretty
--------------
23 MB
```

`citus_table_size (logicalrelid regclass) returns bigint`

Returns the disk space used by all the shards of the specified distributed table, excluding indexes (but including TOAST, free space map, and visibility map).

Arguments:

- *`logicalrelid`* — the name of the distributed table.

The example below shows how to use the function:

```
SELECT pg_size_pretty(citus_table_size('github_events'));
```

```
pg_size_pretty
--------------
37 MB
```

`citus_total_relation_size (logicalrelid regclass, fail_on_error boolean) returns bigint`

Returns the total disk space used by the all the shards of the specified distributed table, including all indexes and TOAST data.

Arguments:

- *`logicalrelid`* — the name of the distributed table.
- *`fail_on_error`*. The default value is `true`.

The example below shows how to use the function:

```
SELECT pg_size_pretty(citus_total_relation_size('github_events'));
```

```
pg_size_pretty
--------------
73 MB
```

`citus_stat_statements_reset () returns void`

Removes all rows from the citus_stat_statements table. Note that this works independently from the `pg_stat_statements_reset` function. To reset all stats, call both functions.

J.5.7.5.1.3. Cluster Management And Repair Functions

`citus_move_shard_placement (shard_id bigint, source_node_name text, source_node_port integer, target_node_name text, target_node_port integer, shard_transfer_mode citus.shard_transfer_mode) returns void`

Moves a given shard (and shards co-located with it) from one node to another. It is typically used indirectly during shard rebalancing rather than being called directly by a database administrator.

There are two ways to move the data: blocking or non-blocking. The blocking approach means that during the move all modifications to the shard are paused. The second way, which avoids blocking shard writes, relies on Postgres Pro 10 logical replication.

After a successful move operation, shards in the source node get deleted. If the move fails at any point, this function throws an error and leaves the source and target nodes unchanged.

Arguments:

- *shard_id* — the ID of the shard to be moved.
- *source_node_name* — the DNS name of the node on which the healthy shard placement is present ("source" node).
- *source_node_port* — the port on the source worker node on which the database server is listening.
- *target_node_name* — the DNS name of the node on which the invalid shard placement is present ("target" node).
- *target_node_port* — the port on the target worker node on which the database server is listening.
- *shard_transfer_mode* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker `COPY` command. The allowed values of this optional argument are:
  - `auto` — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - `force_logical` — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - `block_writes` — use `COPY` (blocking writes) for tables lacking primary key or replica identity.

The example below shows how to use the function:

```
SELECT citus_move_shard_placement(12345, 'from_host', 5432, 'to_host', 5432);
```

```
citus_rebalance_start (rebalance_strategy name, drain_only boolean, shard_transfer_mode
citus.shard_transfer_mode) returns bigint
```

Moves table shards to make them evenly distributed among the workers. It begins a background job to do the rebalancing and returns immediately.

The rebalancing process first calculates the list of moves it needs to make in order to ensure that the cluster is balanced within the given threshold. Then, it moves shard placements one by one from the source node to the destination node and updates the corresponding shard metadata to reflect the move.

Every shard is assigned a cost when determining whether shards are "evenly distributed". By default each shard has the same cost (a value of 1), so distributing to equalize the cost across workers is the same as equalizing the number of shards on each. The constant cost strategy is called `by_shard_count` and is the default rebalancing strategy.

The `by_shard_count` strategy is appropriate under these circumstances:

- The shards are roughly the same size.
- The shards get roughly the same amount of traffic.
- Worker nodes are all the same size/type.
- Shards have not been pinned to particular workers.

If any of these assumptions do not hold, then rebalancing using the `by_shard_count` strategy can result in a bad plan.

If any of these assumptions do not hold, then rebalancing using the `by_shard_count` strategy can result in a bad plan.

The default rebalancing starategy is `by_disk_size`. You can always customize the strategy, using the *rebalance_strategy* parameter.

It is advisable to call the get_rebalance_table_shards_plan function before `citus_rebalance_start` to see and verify the actions to be performed.

Arguments:

- *`rebalance_strategy`* — name of a strategy in the pg_dist_rebalance_strategy table. If this argument is omitted, the function chooses the default strategy, as indicated in the table. The default value of this optional argument is `NULL`.
- *`drain_only`*. When `true`, move shards off worker nodes who have `shouldhaveshards` set to `false` in the pg_dist_node table; move no other shards. The default value of this optional argument is `false`.
- *`shard_transfer_mode`* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker `COPY` command. The allowed values of this optional argument are:
  - `auto` — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - `force_logical` — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - `block_writes` — use `COPY` (blocking writes) for tables lacking primary key or replica identity.

The example below will attempt to rebalance shards:

```
SELECT citus_rebalance_start();
NOTICE:  Scheduling...
NOTICE:  Scheduled as job 1337.
DETAIL:  Rebalance scheduled as background job 1337.
HINT:  To monitor progress, run: SELECT details FROM citus_rebalance_status();
```

`citus_rebalance_status () returns table`

Allows you to monitor the progress of the rebalance. Returns immediately, while the rebalance continues as a background job.

To get general information about the rebalance, you can select all columns from the status. This shows the basic state of the job:

```
SELECT * FROM citus_rebalance_status();

.
 job_id |  state   | job_type  |           description           |
 started_at           |          finished_at          | details
--------+----------+-----------+---------------------------------
+-------------------------------+-------------------------------+-----------
      4 | running  | rebalance | Rebalance colocation group 1    | 2022-08-09
 21:57:27.833055+02 | 2022-08-09 21:57:27.833055+02 | { ... }
```

Rebalancer specifics live in the `details` column, in JSON format:

```
SELECT details FROM citus_rebalance_status();

{
    "phase": "copy",
    "phase_index": 1,
    "phase_count": 3,
    "last_change":"2022-08-09 21:57:27",
    "colocations": {
        "1": {
            "shard_moves": 30,
            "shard_moved": 29,
            "last_move":"2022-08-09 21:57:27"
        },
        "1337": {
            "shard_moves": 130,
```

```
                "shard_moved": 0
            }
        }
    }
```

`citus_rebalance_stop () returns void`

Cancels the rebalance in progress, if any.

`citus_rebalance_wait () returns void`

Blocks until a running rebalance is complete. If no rebalance is in progress when this function is called, then the function returns immediately.

The function can be useful for scripts or benchmarking.

`get_rebalance_table_shards_plan () returns table`

Outputs the planned shard movements of the citus_rebalance_start function without performing them. While it is unlikely, this function can output a slightly different plan than what a `citus_rebalance_start` call with the same arguments will do. This could happen because they are not executed at the same time, so facts about the cluster, e.g. disk space, might differ between the calls. The function returns tuples containing the following columns:

- `table_name` — the table whose shards would move.
- `shardid` — the shard in question.
- `shard_size` — the size, in bytes.
- `sourcename` — the hostname of the source node.
- `sourceport` — the port of the source node.
- `targetname` — the hostname of the destination node.
- `targetport` — the port of the destination node.

Arguments:

- A superset of the arguments for the citus_rebalance_start function: *`relation`*, *`threshold`*, *`max_shard_moves`*, *`excluded_shard_list`*, and *`drain_only`*.

`get_rebalance_progress () returns table`

Once the shard rebalance begins, this function lists the progress of every shard involved. It monitors the moves planned and executed by the citus_rebalance_start function. The function returns tuples containing the following columns:

- `sessionid` — the Postgres Pro PID of the rebalance monitor.
- `table_name` — the table whose shards are moving.
- `shardid` — the shard in question.
- `shard_size` — the size of the shard, in bytes.
- `sourcename` — the hostname of the source node.
- `sourceport` — the port of the source node.
- `targetname` — the hostname of the destination node.
- `targetport` — the port of the destination node.
- `progress`. The following values may be returned: `0` — waiting to be moved, `1` — moving, `2` — complete.
- `source_shard_size` — the size of the shard on the source node, in bytes.
- `target_shard_size` — the size of the shard on the target node, in bytes.

The example below shows how to use the function:

```
SELECT * FROM get_rebalance_progress();
```

```
┌────────────┬────────────┬─────────┬────────────┬──────────────┬────────────┬──────────────
│ sessionid  │ table_name │ shardid │ shard_size │  sourcename  │ sourceport │
 targetname   │ targetport │ progress │ source_shard_size │ target_shard_size │
```

```
┌────────────┬──────────┬──────────┬──────────────┬──────────────────┬──────────────┬──────────────

```

`citus_add_rebalance_strategy (name name, shard_cost_function regproc, node_capacity_function regproc, shard_allowed_on_node_function regproc, default_threshold float4, minimum_threshold float4, improvement_threshold float4) returns void`

Append a row to the pg_dist_rebalance_strategy table.

Arguments:

- *`name`* — the identifier for the new strategy.
- *`shard_cost_function`* — identifies the function used to determine the “cost” of each shard.
- *`node_capacity_function`* — identifies the function to measure node capacity.
- *`shard_allowed_on_node_function`* — identifies the function that determines which shards can be placed on which nodes.
- *`default_threshold`* — floating point threshold that tunes how precisely the cumulative shard cost should be balanced between nodes.
- *`minimum_threshold`* — safeguard column that holds the minimum value allowed for the threshold argument of the citus_rebalance_start function. The default value is `0`.
- *`improvement_threshold`*. The default value is `0`.

`citus_set_default_rebalance_strategy (name text) returns void`

Update the pg_dist_rebalance_strategy table changing the strategy named by its argument to be the default chosen when rebalancing shards.

Arguments:

- *`name`* — the name of the strategy in the `pg_dist_rebalance_strategy` table.

The example below shows how to use the function:

```
SELECT citus_set_default_rebalance_strategy('by_disk_size');
```

`citus_remote_connection_stats () returns setof record`

Shows the number of active connections to each remote node.

The example below shows how to use the function:

```
SELECT * FROM citus_remote_connection_stats();

.
    hostname    | port | database_name | connection_count_to_node
----------------+------+---------------+--------------------------
 citus_worker_1 | 5432 | postgres      |                        3
(1 row)
```

`citus_drain_node (nodename text, nodeport integer, shard_transfer_mode citus.shard_transfer_mode, rebalance_strategy name) returns void`

Moves shards off the designated node and onto other nodes who have `shouldhaveshards` set to `true` in the pg_dist_node table. This function is designed to be called prior to removing a node from the cluster, i.e. turning the node's physical server off.

Arguments:

- *nodename* — the DNS name of the node to be drained.
- *nodeport* — the port number of the node to be drained.
- *shard_transfer_mode* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker COPY command. The allowed values of this optional argument are:
  - auto — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - force_logical — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - block_writes — use COPY (blocking writes) for tables lacking primary key or replica identity.
- *rebalance_strategy* — the name of a strategy in the pg_dist_rebalance_strategy table. If this argument is omitted, the function chooses the default strategy, as indicated in the table. The default value of this optional argument is NULL.

Here are the typical steps to remove a single node (for example '10.0.0.1' on a standard Postgres Pro port):

1. Drain the node.

   ```
   SELECT * FROM citus_drain_node('10.0.0.1', 5432);
   ```

2. Wait until the command finishes.
3. Remove the node.

When draining multiple nodes it is recommended to use the citus_rebalance_start function instead. Doing so allows citus to plan ahead and move shards the minimum number of times.

1. Run this for each node that you want to remove:

   ```
   SELECT * FROM citus_set_node_property(node_hostname, node_port,
    'shouldhaveshards', false);
   ```

2. Drain them all at once with the citus_rebalance_start function:

   ```
   SELECT * FROM citus_rebalance_start(drain_only := true);
   ```

3. Wait until the draining rebalance finishes.
4. Remove the nodes.

```
isolate_tenant_to_new_shard (table_name regclass, tenant_id "any", cascade_option text,
shard_transfer_mode citus.shard_transfer_mode) returns bigint
```

Creates a new shard to hold rows with a specific single value in the distribution column. It is especially handy for the multi-tenant citus use case, where a large tenant can be placed alone on its own shard and ultimately its own physical node. To learn more, see the Tenant Isolation section. The function returns the unique ID assigned to the newly created shard.

Arguments:

- *table_name* — the name of the table to get a new shard.
- *tenant_id* — the value of the distribution column which will be assigned to the new shard.
- *cascade_option*. When set to CASCADE, also isolates a shard from all tables in the current table's co-locating tables.
- *shard_transfer_mode* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker COPY command. The allowed values of this optional argument are:
  - auto — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - force_logical — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - block_writes — use COPY (blocking writes) for tables lacking primary key or replica identity.

The example below shows how to create a new shard to hold the lineitems for tenant 135:

```
SELECT isolate_tenant_to_new_shard('lineitem', 135);

┌─────────────────────────────┐
│ isolate_tenant_to_new_shard │
├─────────────────────────────┤
│                      102240 │
└─────────────────────────────┘
```

`citus_create_restore_point (name text) returns pg_lsn`

Temporarily blocks writes to the cluster, and creates a named restore point on all nodes. This function is similar to pg_create_restore_point, but applies to all nodes and makes sure the restore point is consistent across them. This function is well suited to doing point-in-time recovery, and cluster forking. The function returns the `coordinator_lsn` value, i.e. the log sequence number of the restore point in the coordinator node WAL.

Arguments:

- *`name`* — the name of the restore point to create.

The example below shows how to use the function:

```
SELECT citus_create_restore_point('foo');

┌─────────────────────────────┐
│ citus_create_restore_point  │
├─────────────────────────────┤
│ 0/1EA2808                   │
└─────────────────────────────┘
```

J.5.7.5.2. citus Tables and Views

J.5.7.5.2.1. Coordinator Metadata

citus divides each distributed table into multiple logical shards based on the distribution column. The coordinator then maintains metadata tables to track statistics and information about the health and location of these shards. In this section, we describe each of these metadata tables and their schema. You can view and query these tables using SQL after logging into the coordinator node.

The `pg_dist_partition` Table

The `pg_dist_partition` table stores metadata about which tables in the database are distributed. For each distributed table, it also stores information about the distribution method and detailed information about the distribution column.

Name	Type	Description
logicalrelid	regclass	Distributed table to which this row corresponds. This value references the `relfilenode` column in the pg_class system catalog table.
partmethod	char	The method used for partitioning / distribution. The values of this column corresponding to different distribution methods are: hash — `h`, reference table — `n`.
partkey	text	Detailed information about the distribution column including column number, type, and other relevant information.
colocationid	integer	Co-location group to which this table belongs. Tables in the same group allow co-located joins and distributed rollups among other optimizations. This value references the `colocationid` column in the pg_dist_colocation table.
repmodel	char	The method used for data replication. The values of this column corresponding to different replication methods are: Postgres Pro streaming replication — `s`, two-phase commit (for reference tables) — `t`.

```
SELECT * FROM pg_dist_partition;
 logicalrelid  | partmethod |
   partkey                                                    | colocationid |
 repmodel
---------------+------------
+------------------------------------------------------------------------------------
+--------------+----------
 github_events | h          | {VAR :varno 1 :varattno 4 :vartype 20 :vartypmod
 -1 :varcollid 0 :varlevelsup 0 :varnoold 1 :varoattno 4 :location -1} |          2 |
 s
 (1 row)
```

The pg_dist_shard Table

The `pg_dist_shard` table stores metadata about individual shards of a table. This includes information about which distributed table the shard belongs to and statistics about the distribution column for that shard. In case of hash distributed tables, they are hash token ranges assigned to that shard. These statistics are used for pruning away unrelated shards during `SELECT` queries.

Name	Type	Description
logicalrelid	regclass	Distributed table to which this shard belongs. This value references the `relfilenode` column in the pg_class system catalog table.
shardid	bigint	Globally unique identifier assigned to this shard.
shardstorage	char	Type of storage used for this shard. Different storage types are discussed in the table below.
shardminvalue	text	For hash distributed tables, minimum hash token value assigned to that shard (inclusive).
shardmaxvalue	text	For hash distributed tables, maximum hash token value assigned to that shard (inclusive).

```
SELECT * FROM pg_dist_shard;
 logicalrelid  | shardid | shardstorage | shardminvalue | shardmaxvalue
---------------+---------+--------------+---------------+---------------
 github_events |  102026 | t            | 268435456     | 402653183
 github_events |  102027 | t            | 402653184     | 536870911
 github_events |  102028 | t            | 536870912     | 671088639
 github_events |  102029 | t            | 671088640     | 805306367
 (4 rows)
```

The `shardstorage` column in `pg_dist_shard` indicates the type of storage used for the shard. A brief overview of different shard storage types and their representation is below.

Storage Type	`shardstorage` value	Description
TABLE	`t`	Indicates that shard stores data belonging to a regular distributed table.
COLUMNAR	`c`	Indicates that shard stores columnar data. (Used by distributed *cstore_fdw* tables).
FOREIGN	`f`	Indicates that shard stores foreign data. (Used by distributed file_fdw tables).

The citus_shards View

In addition to the low-level shard metadata table described above, citus provides the `citus_shards` view to easily check:

- Where each shard is (node and port),
- What kind of table it belongs to, and
- Its size.

This view helps you inspect shards to find, among other things, any size imbalances across nodes.

```
SELECT * FROM citus_shards;

.
 table_name | shardid | shard_name    | citus_table_type | colocation_id | nodename  |
 nodeport | shard_size
------------+---------+--------------+------------------+---------------+-----------
+----------+------------
 dist       |  102170 | dist_102170   | distributed      |            34 | localhost |
   9701 |   90677248
 dist       |  102171 | dist_102171   | distributed      |            34 | localhost |

   9701 |     933888
 dist2      |  102176 | dist2_102176 | distributed      |            34 | localhost |
   9702 |     950272
 dist2      |  102177 | dist2_102177 | distributed      |            34 | localhost |
   9701 |     942080
 dist2      |  102178 | dist2_102178 | distributed      |            34 | localhost |
   9702 |     933888
```

The `colocation_id` refers to the colocation group. For more info about `citus_table_type`, see the Table Types section.

The `pg_dist_placement` Table

The `pg_dist_placement` table tracks the location of shards on worker nodes. Each shard assigned to a specific node is called a shard placement. This table stores information about the health and location of each shard placement.

Name	Type	Description
placementid	bigint	Unique auto-generated identifier for each individual placement.
shardid	bigint	Shard identifier associated with this placement. This value references the `shardid` column in the pg_dist_shard catalog table.
shardstate	int	Describes the state of this placement. Different shard states are discussed in the section below.
shardlength	bigint	For hash distributed tables, zero.
groupid	int	Identifier used to denote a group of one primary server and zero or more secondary servers.

```
SELECT * FROM pg_dist_placement;
  placementid | shardid | shardstate | shardlength | groupid
 -------------+---------+------------+-------------+---------
             1 |  102008 |          1 |           0 |       1
             2 |  102008 |          1 |           0 |       2
             3 |  102009 |          1 |           0 |       2
```

```
 4 |  102009 |          1 |            0 |        3
 5 |  102010 |          1 |            0 |        3
 6 |  102010 |          1 |            0 |        4
 7 |  102011 |          1 |            0 |        4
```

The `pg_dist_node` Table

The `pg_dist_node` table contains information about the worker nodes in the cluster.

Name	Type	Description
nodeid	int	Auto-generated identifier for an individual node.
groupid	int	Identifier used to denote a group of one primary server and zero or more secondary servers. By default it is the same as the `nodeid`.
nodename	text	Host name or IP Address of the Postgres Pro worker node.
nodeport	int	Port number on which the Postgres Pro worker node is listening.
noderack	text	Rack placement information for the worker node. This is an optional column.
hasmetadata	boolean	Reserved for internal use.
isactive	boolean	Whether the node is active accepting shard placements.
noderole	text	Whether the node is a primary or secondary.
nodecluster	text	The name of the cluster containing this node.
metadatasynced	boolean	Reserved for internal use.
shouldhaveshards	boolean	If false, shards will be moved off node (drained) when rebalancing, nor will shards from new distributed tables be placed on the node, unless they are co-located with shards already there.

```
SELECT * FROM pg_dist_node;
 nodeid | groupid | nodename  | nodeport | noderack | hasmetadata | isactive | noderole
 | nodecluster | metadatasynced | shouldhaveshards
--------+---------+-----------+----------+----------+-------------+----------
+----------+-------------+----------------+------------------
      1 |       1 | localhost |    12345 | default  | f           | t        | primary
 | default     | f              | t
      2 |       2 | localhost |    12346 | default  | f           | t        | primary
 | default     | f              | t
      3 |       3 | localhost |    12347 | default  | f           | t        | primary
 | default     | f              | t
(3 rows)
```

The `citus.pg_dist_object` Table

The `citus.pg_dist_object` table contains a list of objects such as types and functions that have been created on the coordinator node and propagated to worker nodes. When an administrator adds new worker nodes to the cluster, citus automatically creates copies of the distributed objects on the new nodes (in the correct order to satisfy object dependencies).

Name	Type	Description
classid	oid	Class of the distributed object
objid	oid	Object ID of the distributed object
objsubid	integer	Object sub-ID of the distributed object, e.g. `attnum`
type	text	Part of the stable address used during upgrades with pg_upgrade

Name	Type	Description
object_names	text[]	Part of the stable address used during upgrades with pg_upgrade
object_args	text[]	Part of the stable address used during upgrades with pg_upgrade
distribution_argument_index	integer	Only valid for distributed functions/procedures
colocationid	integer	Only valid for distributed functions/procedures

“Stable addresses” uniquely identify objects independently of a specific server. citus tracks objects during a Postgres Pro upgrade using stable addresses created with the pg_identify_object_as_address function.

Here is an example of how the create_distributed_function function adds entries to the `citus.pg_dist_object` table:

```
CREATE TYPE stoplight AS enum ('green', 'yellow', 'red');

CREATE OR REPLACE FUNCTION intersection()
RETURNS stoplight AS $$
DECLARE
        color stoplight;
BEGIN
        SELECT *
          FROM unnest(enum_range(NULL::stoplight)) INTO color
         ORDER BY random() LIMIT 1;
        RETURN color;
END;
$$ LANGUAGE plpgsql VOLATILE;

SELECT create_distributed_function('intersection()');

-- Will have two rows, one for the TYPE and one for the FUNCTION
TABLE citus.pg_dist_object;
```

```
-[ RECORD 1 ]---------------+------
classid                    | 1247
objid                      | 16780
objsubid                   | 0
type                       |
object_names               |
object_args                |
distribution_argument_index |
colocationid               |
-[ RECORD 2 ]---------------+------
classid                    | 1255
objid                      | 16788
objsubid                   | 0
type                       |
object_names               |
object_args                |
distribution_argument_index |
colocationid               |
```

The `citus_schemas` View

citus supports schema-based sharding and provides the `citus_schemas` view that shows which schemas have been distributed in the system. The view only lists distributed schemas, local schemas are not displayed.

Name	Type	Description
schema_name	regnamespace	Name of the distributed schema
colocation_id	integer	Co-location ID of the distributed schema
schema_size	text	Human-readable size summary of all objects within the schema
schema_owner	name	Role that owns the schema

Here is an example:

```
schema_name  | colocation_id | schema_size | schema_owner
-------------+---------------+-------------+--------------
user_service |             1 | 0 bytes     | user_service
time_service |             2 | 0 bytes     | time_service
ping_service |             3 | 632 kB      | ping_service
```

The `citus_tables` View

The `citus_tables` view shows a summary of all tables managed by citus (distributed and reference tables). The view combines information from citus metadata tables for an easy, human-readable overview of these table properties:

- Table type
- Distribution column
- Co-location group ID
- Human-readable size
- Shard count
- Owner (database user)
- Access method (`heap` or columnar)

Here is an example:

```
SELECT * FROM citus_tables;
```

```
┌─────────────┬───────────────────┬──────────────────────┬─────────────────┬──────────────┬
│ table_name  │ citus_table_type  │ distribution_column  │ colocation_id   │ table_size   │
 shard_count  │ table_owner  │ access_method  │
├─────────────┼───────────────────┼──────────────────────┼─────────────────┼──────────────┼
│ foo.test    │ distributed       │ test_column          │              1  │ 0 bytes      │
       32    │ citus        │ heap           │
│ ref         │ reference         │ <none>               │              2  │ 24 GB        │
        1    │ citus        │ heap           │
│ test        │ distributed       │ id                   │              1  │ 248 TB       │
       32    │ citus        │ heap           │
└─────────────┴───────────────────┴──────────────────────┴─────────────────┴──────────────┴
```

The `time_partitions` View

citus provides user defined functions to manage partitions for the timeseries use case. It also maintains the `time_partitions` view to inspect the partitions it manages.

The columns of this view are as follows:

- `parent_table` — the table which is partitioned.
- `partition_column` — the column on which the parent table is partitioned.
- `partition` — the name of a partition.
- `from_value` — lower bound in time for rows in this partition.
- `to_value` — upper bound in time for rows in this partition.
- `access_method` — `heap` for row-based storage and `columnar` for columnar storage.

```
SELECT * FROM time_partitions;
```

```
┌──────────────────────────┬──────────────────┬──────────────────────────────────────────────────┬
│      parent_table        │ partition_column │                  partition                       │
     from_value      │      to_value       │ access_method │

└──────────────────────────┴──────────────────┴──────────────────────────────────────────────────┴
```

The `pg_dist_colocation` Table

The `pg_dist_colocation` table contains information about which tables' shards should be placed together, or co-located. When two tables are in the same co-location group, citus ensures shards with the same partition values will be placed on the same worker nodes. This enables join optimizations, certain distributed rollups, and foreign key support. Shard co-location is inferred when the shard counts, and partition column types all match between two tables; however, a custom co-location group may be specified when creating a distributed table, if so desired.

Name	Type	Description
colocationid	int	Unique identifier for the co-location group this row corresponds to
shardcount	int	Shard count for all tables in this co-location group
replicationfactor	int	Replication factor for all tables in this co-location group. (Deprecated)
distributioncolumntype	oid	The type of the distribution column for all tables in this co-location group
distributioncolumncollation	oid	The collation of the distribution column for all tables in this co-location group

```
SELECT * FROM pg_dist_colocation;
  colocationid | shardcount | replicationfactor | distributioncolumntype |
 distributioncolumncollation
 --------------+------------+-------------------+------------------------
+-----------------------------
             2 |         32 |                 1 |                     20 |
               0
  (1 row)
```

The `pg_dist_rebalance_strategy` Table

This table defines strategies that the citus_rebalance_start function can use to determine where to move shards.

Name	Type	Description
name	name	Unique name for the strategy
default_strategy	boolean	Whether citus_rebalance_start should choose this strategy by default. Use citus_set_default_rebalance_strategy to update this column.
shard_cost_function	regproc	Identifier for a cost function, which must take a `shardid` as `bigint` and return its notion of a cost, as type `real`.

Name	Type	Description
node_capacity_function	regproc	Identifier for a capacity function, which must take a `nodeid` as `int` and return its notion of node capacity as type `real`.
shard_allowed_on_node_function	regproc	Identifier for a function that given `shardid bigint` and `nodeidarg int`, returns `boolean` for whether the shard is allowed to be stored on the node.
default_threshold	float4	Threshold for deeming a node too full or too empty, which determines when the citus_rebalance_start function should try to move shards.
minimum_threshold	float4	A safeguard to prevent the threshold argument of citus_rebalance_start from being set too low.
improvement_threshold	float4	Determines when moving a shard is worth it during a rebalance. The rebalancer will move a shard when the ratio of the improvement with the shard move to the improvement without crosses the threshold. This is most useful with the `by_disk_size` strategy.

A citus installation ships with these strategies in the table:

```
SELECT * FROM pg_dist_rebalance_strategy;
```

```
-[ RECORD 1 ]------------------+---------------------------------
name                           | by_shard_count
default_strategy               | f
shard_cost_function            | citus_shard_cost_1
node_capacity_function         | citus_node_capacity_1
shard_allowed_on_node_function | citus_shard_allowed_on_node_true
default_threshold              | 0
minimum_threshold              | 0
improvement_threshold          | 0
-[ RECORD 2 ]------------------+---------------------------------
name                           | by_disk_size
default_strategy               | t
shard_cost_function            | citus_shard_cost_by_disk_size
node_capacity_function         | citus_node_capacity_1
shard_allowed_on_node_function | citus_shard_allowed_on_node_true
default_threshold              | 0.1
minimum_threshold              | 0.01
improvement_threshold          | 0.5
```

The `by_disk_size` strategy assigns every shard the same cost. Its effect is to equalize the shard count across nodes. The default strategy, `by_disk_size`, assigns a cost to each shard matching its disk size in bytes plus that of the shards that are co-located with it. The disk size is calculated using pg_total_relation_size, so it includes indices. This strategy attempts to achieve the same disk space on every node. Note the threshold of 0.1 — it prevents unnecessary shard movement caused by insigificant differences in disk space.

Here are examples of functions that can be used within new shard rebalancer strategies, and registered in the `pg_dist_rebalance_strategy` table with the citus_add_rebalance_strategy function.

- Setting a node capacity exception by hostname pattern:

```
-- Example of node_capacity_function

CREATE FUNCTION v2_node_double_capacity(nodeidarg int)
    RETURNS real AS $$
```

```
    SELECT
        (CASE WHEN nodename LIKE '%.v2.worker.citusdata.com' THEN 2.0::float4 ELSE
 1.0::float4 END)
    FROM pg_dist_node where nodeid = nodeidarg
    $$ LANGUAGE sql;
```

- Rebalancing by number of queries that go to a shard, as measured by the citus_stat_statements table:

```
-- Example of shard_cost_function

CREATE FUNCTION cost_of_shard_by_number_of_queries(shardid bigint)
    RETURNS real AS $$
    SELECT coalesce(sum(calls)::real, 0.001) as shard_total_queries
    FROM citus_stat_statements
    WHERE partition_key is not null
        AND get_shard_id_for_distribution_column('tab', partition_key) = shardid;
$$ LANGUAGE sql;
```

- Isolating a specific shard (10000) on a node (address '10.0.0.1'):

```
-- Example of shard_allowed_on_node_function

CREATE FUNCTION isolate_shard_10000_on_10_0_0_1(shardid bigint, nodeidarg int)
    RETURNS boolean AS $$
    SELECT
        (CASE WHEN nodename = '10.0.0.1' THEN shardid = 10000 ELSE shardid != 10000
 END)
    FROM pg_dist_node where nodeid = nodeidarg
    $$ LANGUAGE sql;

-- The next two definitions are recommended in combination with the above function.
-- This way the average utilization of nodes is not impacted by the isolated shard
CREATE FUNCTION no_capacity_for_10_0_0_1(nodeidarg int)
    RETURNS real AS $$
    SELECT
        (CASE WHEN nodename = '10.0.0.1' THEN 0 ELSE 1 END)::real
    FROM pg_dist_node where nodeid = nodeidarg
    $$ LANGUAGE sql;
CREATE FUNCTION no_cost_for_10000(shardid bigint)
    RETURNS real AS $$
    SELECT
        (CASE WHEN shardid = 10000 THEN 0 ELSE 1 END)::real
    $$ LANGUAGE sql;
```

The `citus_stat_statements` Table

citus provides the `citus_stat_statements` table for stats about how queries are being executed, and for whom. It is analogous to (and can be joined with) the pg_stat_statements view in Postgres Pro, which tracks statistics about query speed.

Name	Type	Description
queryid	bigint	Identifier (good for `pg_stat_statements` joins)
userid	oid	User who ran the query
dbid	oid	Database instance of coordinator
query	text	Anonymized query string
executor	text	citus executor used: adaptive, or `INSERT-SELECT`
partition_key	text	Value of distribution column in router-executed queries, else `NULL`

Name	Type	Description
calls	bigint	Number of times the query was run

```
-- Create and populate distributed table
CREATE TABLE foo ( id int );
SELECT create_distributed_table('foo', 'id');
INSERT INTO foo select generate_series(1,100);

-- Enable stats
-- pg_stat_statements must be in shared_preload_libraries
CREATE EXTENSION pg_stat_statements;

SELECT count(*) from foo;
SELECT * FROM foo where id = 42;

SELECT * FROM citus_stat_statements;
```

Results:

```
-[ RECORD 1 ]-+----------------------------------------------
queryid       | -909556869173432820
userid        | 10
dbid          | 13340
query         | insert into foo select generate_series($1,$2)
executor      | insert-select
partition_key |
calls         | 1
-[ RECORD 2 ]-+----------------------------------------------
queryid       | 3919808845681956665
userid        | 10
dbid          | 13340
query         | select count(*) from foo;
executor      | adaptive
partition_key |
calls         | 1
-[ RECORD 3 ]-+----------------------------------------------
queryid       | 5351346905785208738
userid        | 10
dbid          | 13340
query         | select * from foo where id = $1
executor      | adaptive
partition_key | 42
calls         | 1
```

Caveats:

- The stats data is not replicated and will not survive database crashes or failover.
- Tracks a limited number of queries set by the pg_stat_statements.max configuration parameter. The default value is `5000`.
- To truncate the table, use the citus_stat_statements_reset function.

The `citus_stat_tenants` View

The `citus_stat_tenants` view augments the citus_stat_statements table with information about how many queries each tenant is running. Tracing queries to originating tenants helps, among other things, for deciding when to do tenant isolation.

This view counts recent single-tenant queries happening during a configurable time period. The tally of read-only and total queries for the period increases until the current period ends. After that, the counts

are moved to last period's statistics, which stays constant until expiration. The period length can be set in seconds using `citus.stats_tenants_period`, and is 60 seconds by default.

The view displays up to `citus.stat_tenants_limit` rows (by default `100`). It counts only queries filtered to a single tenant, ignoring queries that apply to multiple tenants at once.

Name	Type	Description
nodeid	int	Node ID from the pg_dist_node
colocation_id	int	ID of the co-location group
tenant_attribute	text	Value in the distribution column identifying tenant
read_count_in_this_period	int	Number of read (`SELECT`) queries for tenant in period
read_count_in_last_period	int	Number of read queries one period of time ago
query_count_in_this_period	int	Number of read/write queries for tenant in time period
query_count_in_last_period	int	Number of read/write queries one period of time ago
cpu_usage_in_this_period	double	Seconds of CPU time spent for this tenant in period
cpu_usage_in_last_period	double	Seconds of CPU time spent for this tenant last period

Tracking tenant level statistics adds overhead, and by default is disabled. To enable it, set `citus.stat_tenants_track` to `'all'`.

By way of example, suppose we have a distributed table called `dist_table`, with distribution column `tenant_id`. Then we make some queries:

```
INSERT INTO dist_table(tenant_id) VALUES (1);
INSERT INTO dist_table(tenant_id) VALUES (1);
INSERT INTO dist_table(tenant_id) VALUES (2);

SELECT count(*) FROM dist_table WHERE tenant_id = 1;
```

The tenant-level statistics will reflect the queries we just made:

```
SELECT tenant_attribute, read_count_in_this_period,
       query_count_in_this_period, cpu_usage_in_this_period
  FROM citus_stat_tenants;
```

```
tenant_attribute | read_count_in_this_period | query_count_in_this_period |
 cpu_usage_in_this_period
------------------+---------------------------+----------------------------
+--------------------------
1                |                         1 |                          3 |
     0.000883
2                |                         0 |                          1 |
     0.000144
```

Distributed Query Activity

In some situations, queries might get blocked on row-level locks on one of the shards on a worker node. If that happens then those queries would not show up in pg_locks on the citus coordinator node.

citus provides special views to watch queries and locks throughout the cluster, including shard-specific queries used internally to build results for distributed queries.

- `citus_stat_activity` — shows the distributed queries that are executing on all nodes. A superset of pg_stat_activity usable wherever the latter is.
- `citus_dist_stat_activity` — the same as `citus_stat_activity` but restricted to distributed queries only, and excluding citus fragments queries.
- `citus_lock_waits` — blocked queries throughout the cluster.

The first two views include all columns of `pg_stat_activity` plus the global PID of the worker that initiated the query.

For example, consider counting the rows in a distributed table:

```
-- Run in one session
-- (with a pg_sleep so we can see it)

SELECT count(*), pg_sleep(3) FROM users_table;
```

We can see the query appear in `citus_dist_stat_activity`:

```
-- Run in another session

SELECT * FROM citus_dist_stat_activity;

-[ RECORD 1 ]----+----------------------------------------
global_pid       | 10000012199
nodeid           | 1
is_worker_query  | f
datid            | 13724
datname          | postgres
pid              | 12199
leader_pid       |
usesysid         | 10
usename          | postgres
application_name | psql
client_addr      |
client_hostname  |
client_port      | -1
backend_start    | 2022-03-23 11:30:00.533991-05
xact_start       | 2022-03-23 19:35:28.095546-05
query_start      | 2022-03-23 19:35:28.095546-05
state_change     | 2022-03-23 19:35:28.09564-05
wait_event_type  | Timeout
wait_event       | PgSleep
state            | active
backend_xid      |

query_id         |
query            | SELECT count(*), pg_sleep(3) FROM users_table;
backend_type     | client backend
```

The `citus_dist_stat_activity` view hides internal citus fragment queries. To see those, we can use the more detailed `citus_stat_activity` view. For instance, the previous `count(*)` query requires information from all shards. Some of the information is in shard `users_table_102039`, which is visible in the query below.

```
SELECT * FROM citus_stat_activity;

-[ RECORD 1 ]----
+----------------------------------------------------------------------
global_pid       | 10000012199
nodeid           | 1
is_worker_query  | f
datid            | 13724
datname          | postgres
pid              | 12199
leader_pid       |
usesysid         | 10
```

```
usename          | postgres
application_name | psql
client_addr      |

query_start      | 2022-03-23 19:32:18.260803-05
state_change     | 2022-03-23 19:32:18.260821-05
wait_event_type  | Timeout
wait_event       | PgSleep
state            | active
backend_xid      |
backend_xmin     | 777
query_id         |
query            | SELECT count(*), pg_sleep(3) FROM users_table;
backend_type     | client backend
-[ RECORD 2 ]----
+-------------------------------------------------------------------------------
global_pid       | 10000012199
nodeid           | 1
is_worker_query  | t
datid            | 13724
datname          | postgres
pid              | 12725
leader_pid       |
usesysid         | 10
usename          | postgres
application_name | citus_internal gpid=10000012199
client_addr      | 127.0.0.1
client_hostname  |
client_port      | 44106
backend_start    | 2022-03-23 19:29:53.377573-05
xact_start       |
query_start      | 2022-03-23 19:32:18.278121-05
state_change     | 2022-03-23 19:32:18.278281-05
wait_event_type  | Client
wait_event       | ClientRead
state            | idle
backend_xid      |
backend_xmin     |
query_id         |
query            | SELECT count(*) AS count FROM public.users_table_102039 users WHERE
 true
backend_type     | client backend
```

The `query` field shows rows being counted in shard `102039`.

Here are examples of useful queries you can build using `citus_stat_activity`:

```
-- Active queries' wait events

SELECT query, wait_event_type, wait_event
  FROM citus_stat_activity
 WHERE state='active';

-- Active queries' top wait events

SELECT wait_event, wait_event_type, count(*)
```

```
  FROM citus_stat_activity
 WHERE state='active'
 GROUP BY wait_event, wait_event_type
 ORDER BY count(*) desc;

-- Total internal connections generated per node by citus

SELECT nodeid, count(*)
  FROM citus_stat_activity
 WHERE is_worker_query
 GROUP BY nodeid;
```

The next view is `citus_lock_waits`. To see how it works, we can generate a locking situation manually. First we will set up a test table from the coordinator:

```
CREATE TABLE numbers AS
  SELECT i, 0 AS j FROM generate_series(1,10) AS i;
SELECT create_distributed_table('numbers', 'i');
```

Then, using two sessions on the coordinator, we can run this sequence of statements:

```
-- Session 1                           -- Session 2
-------------------------------------  -------------------------------------
BEGIN;
UPDATE numbers SET j = 2 WHERE i = 1;
                                       BEGIN;
                                       UPDATE numbers SET j = 3 WHERE i = 1;
                                       -- (this blocks)
```

The `citus_lock_waits` view shows the situation.

```
SELECT * FROM citus_lock_waits;

-[ RECORD 1 ]-------------------------+--------------------------------------
waiting_gpid                          | 10000011981
blocking_gpid                         | 10000011979
blocked_statement                     | UPDATE numbers SET j = 3 WHERE i = 1;
current_statement_in_blocking_process | UPDATE numbers SET j = 2 WHERE i = 1;
waiting_nodeid                        | 1
blocking_nodeid                       | 1
```

In this example the queries originated on the coordinator, but the view can also list locks between queries originating on workers.

J.5.7.5.2.2. Tables on All Nodes

citus has other informational tables and views which are accessible on all nodes, not just the coordinator.

The `pg_dist_authinfo` Table

The `pg_dist_authinfo` table holds authentication parameters used by citus nodes to connect to one another.

Name	Type	Description
nodeid	integer	Node ID from pg_dist_node, or 0, or -1
rolename	name	Postgres Pro role
authinfo	text	Space-separated libpq connection parameters

Upon beginning a connection, a node consults the table to see whether a row with the destination `nodeid` and desired `rolename` exists. If so, the node includes the corresponding `authinfo` string in its libpq connection. A common example is to store a password, like `'password=abc123'`, but you can review the full list of possibilities.

The parameters in `authinfo` are space-separated, in the form `key=val`. To write an empty value, or a value containing spaces, surround it with single quotes, e.g., `keyword='a value'`. Single quotes and backslashes within the value must be escaped with a backslash, i.e., `\'` and `\\`.

The `nodeid` column can also take the special values `0` and `-1`, which mean *all nodes* or *loopback connections*, respectively. If, for a given node, both specific and all-node rules exist, the specific rule has precedence.

```
SELECT * FROM pg_dist_authinfo;

 nodeid | rolename | authinfo
--------+----------+-----------------
    123 | jdoe     | password=abc123
(1 row)
```

The `pg_dist_poolinfo` Table

If you want to use a connection pooler to connect to a node, you can specify the pooler options using `pg_dist_poolinfo`. This metadata table holds the host, port and database name for citus to use when connecting to a node through a pooler.

If pool information is present, citus will try to use these values instead of setting up a direct connection. The `pg_dist_poolinfo` information in this case supersedes pg_dist_node.

Name	Type	Description
nodeid	integer	Node ID from pg_dist_node
poolinfo	text	Space-separated parameters: `host`, `port`, or `dbname`

> **Note**
>
> In some situations citus ignores the settings in `pg_dist_poolinfo`. For instance shard rebalancing is not compatible with connection poolers such as pgbouncer. In these scenarios citus will use a direct connection.

```
-- How to connect to node 1 (as identified in pg_dist_node)

INSERT INTO pg_dist_poolinfo (nodeid, poolinfo)
     VALUES (1, 'host=127.0.0.1 port=5433');
```

J.5.7.5.3. Configuration Reference

There are various configuration parameters that affect the behaviour of citus. These include both standard Postgres Pro parameters and citus specific parameters. To learn more about Postgres Pro configuration parameters, you can visit the Server Configuration chapter.

The rest of this reference aims at discussing citus specific configuration parameters. These parameters can be set similar to Postgres Pro parameters by modifying `postgresql.conf` or by using the `SET` command.

As an example you can update a setting with:

```
ALTER DATABASE citus SET citus.multi_task_query_log_level = 'log';
```

J.5.7.5.3.1. General Configuration

`citus.max_background_task_executors_per_node` (`integer`)

Determines how many background tasks can be executed in parallel at a given time. For instance, these tasks are for shard moves from/to a node. When increasing the value of this parameter, you will

often also want to increase the value of the citus.max_background_task_executors and max_worker_processes parameters. The minimum value is 1, the maximum value is 128. The default value is 1.

citus.max_worker_nodes_tracked (integer)

citus tracks worker nodes' locations and their membership in a shared hash table on the coordinator node. This configuration parameter limits the size of the hash table and consequently the number of worker nodes that can be tracked. The default value is 2048. This parameter can only be set at server start and is effective on the coordinator node.

citus.use_secondary_nodes (enum)

Sets the policy to use when choosing nodes for the SELECT queries. If set to always, the planner will query only nodes whose noderole is marked as secondary in the pg_dist_node table. The allowed values are:

- never — all reads happen on primary nodes. This is the default value.
- always — reads run against secondary nodes instead and INSERT/UPDATE statements are disabled.

citus.cluster_name (text)

Informs the coordinator node planner which cluster it coordinates. Once *cluster_name* is set, the planner will query worker nodes in that cluster alone.

citus.enable_version_checks (boolean)

Upgrading citus version requires a server restart (to pick up the new shared library), as well as running the ALTER EXTENSION UPDATE command. The failure to execute both steps could potentially cause errors or crashes. citus thus validates the version of the code and that of the extension match, and errors out if they do not.

The default value is true, and the parameter is effective on the coordinator. In rare cases, complex upgrade processes may require setting this parameter to false, thus disabling the check.

citus.log_distributed_deadlock_detection (boolean)

Specifies whether to log distributed deadlock detection related processing in the server log. The default value is false.

citus.distributed_deadlock_detection_factor (floating point)

Sets the time to wait before checking for distributed deadlocks. In particular the time to wait will be this value multiplied by the value set in the Postgres Pro deadlock_timeout parameter. The default value is 2. The value of -1 disables distributed deadlock detection.

citus.node_connection_timeout (integer)

Sets the maximum duration to wait for connection establishment, in milliseconds. citus raises an error if the timeout elapses before at least one worker connection is established. This configuration parameter affects connections from the coordinator to workers and workers to each other. The minimum value is 10 milliseconds, the maximum value is 1 hour. The default value is 30 seconds.

The example below shows how to set this parameter:

```
-- Set to 60 seconds
ALTER DATABASE foo
SET citus.node_connection_timeout = 60000;
```

citus.node_conninfo (text)

Sets non-sensitive libpq connection parameters used for all inter-node connections.

The example below shows how to set this parameter:

```
-- key=value pairs separated by spaces.
-- For example, ssl options:

ALTER DATABASE foo
SET citus.node_conninfo =
  'sslrootcert=/path/to/citus.crt sslmode=verify-full';
```

citus supports only a specific subset of the allowed options, namely:

- `application_name`
- `connect_timeout`
- `gsslib` (subject to the runtime presence of optional Postgres Pro features)
- `keepalives`
- `keepalives_count`
- `keepalives_idle`
- `keepalives_interval`
- `krbsrvname` (subject to the runtime presence of optional Postgres Pro features)
- `sslcompression`
- `sslcrl`
- `sslmode` (defaults to `require`)
- `sslrootcert`
- `tcp_user_timeout`

The `citus.node_conninfo` configuration parameter takes effect only on newly opened connections. To force all connections to use the new settings, make sure to reload the Postgres Pro configuration:

```
SELECT pg_reload_conf();
```

`citus.local_hostname` (`text`)

citus nodes need occasionally to connect to themselves for systems operations. By default, they use the `localhost` address to refer to themselves, but this can cause problems. For instance, when a host requires `sslmode=verify-full` for incoming connections, adding `localhost` as an alternative hostname on the SSL certificate is not always desirable or even feasible.

The `citus.local_hostname` configuration parameter selects the hostname a node uses to connect to itself. The default value is `localhost`.

The example below shows how to set this parameter:

```
ALTER SYSTEM SET citus.local_hostname TO 'mynode.example.com';
```

`citus.show_shards_for_app_name_prefixes` (`text`)

By default, citus hides shards from the list of tables Postgres Pro gives to SQL clients. It does this because there are multiple shards per distributed table, and the shards can be distracting to the SQL client.

The `citus.show_shards_for_app_name_prefixes` configuration parameter allows shards to be displayed for selected clients that want to see them. The default value is `''`.

The example below shows how to set this parameter:

```
-- Show shards to psql only (hide in other clients, like pgAdmin)

SET citus.show_shards_for_app_name_prefixes TO 'psql';

-- Also accepts a comma-separated list

SET citus.show_shards_for_app_name_prefixes TO 'psql,pg_dump';
```

`citus.rebalancer_by_disk_size_base_cost` (`integer`)

When using the `by_disk_size` rebalance strategy each shard group will get this cost in bytes added to its actual disk size. This is used to avoid creating a bad balance when there is very little data in some of the shards. The assumption is that even empty shards have some cost, because of parallelism and because empty shard groups will likely grow in the future. The default value is `100` MB.

J.5.7.5.3.2. Query Statistics

`citus.stat_statements_purge_interval` (`integer`)

Sets the frequency at which the maintenance daemon removes records from the citus_stat_statements table that are unmatched in the pg_stat_statements view. This configuration parameter sets the time interval between purges in seconds, with the default value of `10`. The value of `0` disables the purges. This parameter is effective on the coordinator and can be changed at runtime.

The example below shows how to set this parameter:

```
SET citus.stat_statements_purge_interval TO 5;
```

`citus.stat_statements_max` (`integer`)

The maximum number of rows to store in the citus_stat_statements table. The default value is `50000` and may be changed to any value in the range of `1000` - `10000000`. Note that each row requires 140 bytes of storage, so setting `citus.stat_statements_max` to its maximum value of 10M would consume 1.4GB of memory.

Changing this configuration parameter will not take effect until Postgres Pro is restarted.

`citus.stat_statements_track` (`enum`)

Recording statistics for citus_stat_statements requires extra CPU resources. When the database is experiencing load, the administrator may wish to disable statement tracking. The `citus.stat_statements_track` configuration parameter can turn tracking on and off. The allowed values are:

- `all` — track all statements. This is the default value.
- `none` — disable tracking.

`citus.stat_tenants_untracked_sample_rate` (`floating point`)

Sampling rate for new tenants in the citus_stat_tenants view. The rate can be of range between `0.0` and `1.0`. The default value is `1.0` meaning 100% of untracked tenant queries are sampled. Setting it to a lower value means that the already tracked tenants have 100% queries sampled, but tenants that are currently untracked are sampled only at the provided rate.

J.5.7.5.3.3. Data Loading

`citus.shard_count` (`integer`)

Sets the shard count for hash-partitioned tables and defaults to `32`. This value is used by the create_distributed_table function when creating hash-partitioned tables. This parameter can be set at runtime and is effective on the coordinator.

`citus.metadata_sync_mode` (`enum`)

> **Note**
>
> This configuration parameter requires superuser access to change.

This configuration parameter determines how citus synchronizes metadata across nodes. By default, citus updates all metadata in a single transaction for consistency. However, Postgres Pro has a hard memory limit related to cache invalidations, and citus metadata syncing for a large cluster can fail from memory exhaustion.

As a workaround, citus provides an optional nontransactional sync mode, which uses a series of smaller transactions. While this mode works in limited memory, there is a possibility of transactions failing and leaving metadata in an inconsistency state. To help with this potential problem, nontransactional metadata sync is designed as an idempotent action, so you can re-run it repeatedly if needed.

There allowed values for this configiration parameters are as follows:

- `transactional` — synchronize all metadata in a single transaction. This is the default value.
- `nontransactional` — synchronize metadata using multiple small transactions.

The example below shows how to set this parameter:

```
-- To add a new node and sync nontransactionally

SET citus.metadata_sync_mode TO 'nontransactional';
SELECT citus_add_node(<ip>, <port>);

-- To manually (re)sync

SET citus.metadata_sync_mode TO 'nontransactional';
SELECT start_metadata_sync_to_all_nodes();
```

We advise trying transactional mode first and switching to nontransactional only if a memory failure occurs.

J.5.7.5.3.4. Planner Configuration

`citus.local_table_join_policy` (`enum`)

Determines how citus moves data when doing a join between local and distributed tables. Customizing the join policy can help reduce the amount of data sent between worker nodes.

citus will send either the local or distributed tables to nodes as necessary to support the join. Copying table data is referred to as a “conversion”. If a local table is converted, then it will be sent to any workers that need its data to perform the join. If a distributed table is converted, then it will be collected in the coordinator to support the join. The citus planner will send only the necessary rows doing a conversion.

There are four modes available to express conversion preference:

- `auto` — citus will convert either all local or all distributed tables to support local and distributed table joins. citus decides which to convert using a heuristic. It will convert distributed tables if they are joined using a constant filter on a unique index (such as a primary key). This ensures less data gets moved between workers. This is the default value.
- `never` — citus will not allow joins between local and distributed tables.
- `prefer-local` — citus will prefer converting local tables to support local and distributed table joins.
- `prefer-distributed` — citus will prefer converting distributed tables to support local and distributed table joins. If the distributed tables are huge, using this option might result in moving lots of data between workers.

For example, assume `citus_table` is a distributed table distributed by the column `x`, and that `postgres_table` is a local table:

```
CREATE TABLE citus_table(x int primary key, y int);
SELECT create_distributed_table('citus_table', 'x');

CREATE TABLE postgres_table(x int, y int);

-- Even though the join is on primary key, there isn't a constant filter
-- hence postgres_table will be sent to worker nodes to support the join
SELECT * FROM citus_table JOIN postgres_table USING (x);
```

```
-- There is a constant filter on a primary key, hence the filtered row
-- from the distributed table will be pulled to coordinator to support the join
SELECT * FROM citus_table JOIN postgres_table USING (x) WHERE citus_table.x = 10;

SET citus.local_table_join_policy to 'prefer-distributed';
-- Since we prefer distributed tables, citus_table will be pulled to coordinator
-- to support the join. Note that citus_table can be huge
SELECT * FROM citus_table JOIN postgres_table USING (x);

SET citus.local_table_join_policy to 'prefer-local';
-- Even though there is a constant filter on primary key for citus_table
-- postgres_table will be sent to necessary workers because we are using 'prefer-
local'
SELECT * FROM citus_table JOIN postgres_table USING (x) WHERE citus_table.x = 10;
```

`citus.limit_clause_row_fetch_count` (`integer`)

Sets the number of rows to fetch per task for limit clause optimization. In some cases, `SELECT` queries with `LIMIT` clauses may need to fetch all rows from each task to generate results. In those cases, and where an approximation would produce meaningful results, this configuration parameter sets the number of rows to fetch from each shard. Limit approximations are disabled by default and this parameter is set to `-1`. This value can be set at runtime and is effective on the coordinator.

`citus.count_distinct_error_rate` (`floating point`)

citus can calculate `count(distinct)` approximates using the Postgres Pro hll extension. This configuration parameter sets the desired error rate when calculating `count(distinct)`: `0.0`, which is the default value, disables approximations for `count(distinct)`, and `1.0`, which provides no guarantees about the accuracy of results. We recommend setting this parameter to `0.005` for best results. This value can be set at runtime and is effective on the coordinator.

`citus.task_assignment_policy` (`enum`)

> **Note**
>
> This configuration parameter is applicable for queries against reference tables.

Sets the policy to use when assigning tasks to workers. The coordinator assigns tasks to workers based on shard locations. This configuration parameter specifies the policy to use when making these assignments. Currently, there are three possible task assignment policies, which can be used:

- `greedy` — aims at evenly distributing tasks across workers. This is the default value.
- `round-robin` — assigns tasks to workers in a `round-robin` fashion alternating between different replicas. This enables much better cluster utilization when the shard count for a table is low compared to the number of workers.
- `first-replica` — assigns tasks on the basis of the insertion order of placements (replicas) for the shards. In other words, the fragment query for a shard is simply assigned to the worker which has the first replica of that shard. This method allows you to have strong guarantees about which shards will be used on which nodes (i.e. stronger memory residency guarantees).

This configuration parameter can be set at runtime and is effective on the coordinator.

`citus.enable_non_colocated_router_query_pushdown` (`boolean`)

Enables router planner for the queries that reference non-colocated distributed tables.

Normally, router planner is only enabled for the queries that reference co-located distributed tables because it is not guaranteed to have the target shards always on the same node, e.g., after rebalancing the shards. For this reason, while enabling this flag allows some degree of optimization for

the queries that reference non-colocated distributed tables, it is not guaranteed that the same query will work after rebalancing the shards or altering the shard count of one of those distributed tables. The default value is `off`.

J.5.7.5.3.5. Intermediate Data Transfer

`citus.max_intermediate_result_size` (`integer`)

The maximum size in KB of intermediate results for CTEs that are unable to be pushed down to worker nodes for execution, and for complex subqueries. The default is `1` GB and a value of `-1` means no limit. Queries exceeding the limit will be canceled and produce an error message.

J.5.7.5.3.6. DDL

`citus.enable_ddl_propagation` (`boolean`)

Specifies whether to automatically propagate DDL changes from the coordinator to all workers. The default value is `true`. Because some schema changes require an access exclusive lock on tables and because the automatic propagation applies to all workers sequentially it can make a citus cluster temporarily less responsive. You may choose to disable this setting and propagate changes manually.

> **Note**
>
> For a list of DDL propagation support, see the Modifying Tables section.

`citus.enable_local_reference_table_foreign_keys` (`boolean`)

Allows foreign keys to be created between reference and local tables. For the feature to work, the coordinator node must be registered with itself, using the citus_add_node function. The default value is `true`.

Note that foreign keys between reference tables and local tables come at a slight cost. When you create the foreign key, citus must add the plain table to its metadata and track it in the pg_dist_partition table. Local tables that are added to metadata inherit the same limitations as reference tables (see the Creating and Modifying Distributed Objects (DDL) and SQL Support and Workarounds sections).

If you drop the foreign keys, citus will automatically remove such local tables from metadata, which eliminates such limitations on those tables.

`citus.enable_change_data_capture` (`boolean`)

Causes citus to alter the wal2json and pgoutput logical decoders to work with distributed tables. Specifically, it rewrites the names of shards (e.g. `foo_102027`) in decoder output to the base names of the distributed tables (e.g. `foo`). It also avoids publishing duplicate events during tenant isolation and shard split/move/rebalance operations. The default value is `false`.

`citus.enable_schema_based_sharding` (`boolean`)

With the parameter set to `ON` all created schemas will be distributed by default. Distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas will be automatically converted to co-located distributed tables without a shard key. This parameter can be modified for individual sessions.

To learn how to use this configuration parameter, see the Microservices section.

J.5.7.5.3.7. Executor Configuration

`citus.all_modifications_commutative` (`boolean`)

citus enforces commutativity rules and acquires appropriate locks for modify operations in order to guarantee correctness of behavior. For example, it assumes that an `INSERT` statement commutes with another `INSERT` statement, but not with an `UPDATE` or `DELETE` statement. Similarly, it assumes that an `UPDATE` or `DELETE` statement does not commute with another `UPDATE` or `DELETE` statement. This means that `UPDATE` and `DELETE` statements require citus to acquire stronger locks.

If you have UPDATE statements that are commutative with your INSERTs or other UPDATEs, then you can relax these commutativity assumptions by setting this parameter to true. When this parameter is set to true, all commands are considered commutative and claim a shared lock, which can improve overall throughput. This parameter can be set at runtime and is effective on the coordinator.

citus.multi_task_query_log_level (enum)

Sets a log-level for any query which generates more than one task (i.e. which hits more than one shard). This is useful during a multi-tenant application migration, as you can choose to error or warn for such queries, to find them and add the tenant_id filter to them. This parameter can be set at runtime and is effective on the coordinator. The default value for this parameter is off. The following values are supported:

- off — turns off logging any queries, which generate multiple tasks (i.e. span multiple shards).
- debug — logs statement at the DEBUG severity level.
- log — logs statement at the LOG severity level. The log line will include the SQL query that was run.
- notice — logs statement at the NOTICE severity level.
- warning — logs statement at the WARNING severity level.
- error — logs statement at the ERROR severity level.

Note that it may be useful to use error during development testing and a lower log-level like log during actual production deployment. Choosing log will cause multi-task queries to appear in the database logs with the query itself shown after STATEMENT.

```
LOG:  multi-task query about to be executed
HINT:  Queries are split to multiple tasks if they have to be split into several
 queries on the workers.
STATEMENT:  SELECT * FROM foo;
```

citus.propagate_set_commands (enum)

Determines which SET commands are propagated from the coordinator to workers. The default value is none. The following values are supported:

- none — no SET commands are propagated.
- local — only SET LOCAL commands are propagated.

citus.enable_repartition_joins (boolean)

Ordinarily, attempting to perform repartition joins with the adaptive executor will fail with an error message. However, setting this configuration parameter to true allows citus to perform the join. The default value is false.

citus.enable_repartitioned_insert_select (boolean)

By default, an INSERT INTO … SELECT statement that cannot be pushed down will attempt to repartition rows from the SELECT statement and transfer them between workers for insertion. However, if the target table has too many shards then repartitioning will probably not perform well. The overhead of processing the shard intervals when determining how to partition the results is too great. Repartitioning can be disabled manually by setting this configuration parameter to false.

citus.enable_binary_protocol (boolean)

Setting this parameter to true instructs the coordinator node to use Postgres Pro binary serialization format (when applicable) to transfer data with workers. Some column types do not support binary serialization.

Enabling this parameter is mostly useful when the workers must return large amounts of data. Examples are when a lot of rows are requested, the rows have many columns, or they use big types such as hll type from the hll extension.

The default value is true. When set to false, all results are encoded and transferred in text format.

`citus.max_shared_pool_size` (`integer`)

Specifies the maximum number of connections that the coordinator node, across all simultaneous sessions, is allowed to make per worker node. Postgres Pro must allocate fixed resources for every connection and this configuration parameter helps ease connection pressure on workers.

Without connection throttling, every multi-shard query creates connections on each worker proportional to the number of shards it accesses (in particular, up to `#shards/#workers`). Running dozens of multi-shard queries at once can easily hit worker nodes' max_connections limit, causing queries to fail.

By default, the value is automatically set equal to the coordinator's own `max_connections`, which is not guaranteed to match that of the workers (see the note below). The value `-1` disables throttling.

> **Note**
>
> There are certain operations that do not obey this parameter, most importantly repartition joins. That is why it can be prudent to increase the `max_connections` on the workers a bit higher than `max_connections` on the coordinator. This gives extra space for connections required for repartition queries on the workers.

`citus.max_adaptive_executor_pool_size` (`integer`)

Whereas citus.max_shared_pool_size limits worker connections across all sessions, the `citus.max_adaptive_executor_pool_size` limits worker connections from just the *current* session. This parameter is useful for:

- Preventing a single backend from getting all the worker resources.
- Providing priority management: designate low priority sessions with low `citus.max_adaptive_executor_pool_size` value and high priority sessions with higher values.

The default value is `16`.

`citus.executor_slow_start_interval` (`integer`)

Time to wait between opening connections to the same worker node, in milliseconds.

When the individual tasks of a multi-shard query take very little time, they can often be finished over a single (often already cached) connection. To avoid redundantly opening additional connections, the executor waits between connection attempts for the configured number of milliseconds. At the end of the interval, it increases the number of connections it is allowed to open next time.

For long queries (those taking >`500` ms), slow start might add latency, but for short queries it is faster. The default value is `10` ms.

`citus.max_cached_conns_per_worker` (`integer`)

Each backend opens connections to the workers to query the shards. At the end of the transaction, the configured number of connections is kept open to speed up subsequent commands. Increasing this value will reduce the latency of multi-shard queries but will also increase overhead on the workers.

The default value is `1`. A larger value such as `2` might be helpful for clusters that use a small number of concurrent sessions, but it's not wise to go much further (e.g. `16` would be too high).

`citus.force_max_query_parallelization` (`boolean`)

Simulates the deprecated and now nonexistent real-time executor. This is used to open as many connections as possible to maximize query parallelization.

When this configuration parameter is enabled, citus will force the adaptive executor to use as many connections as possible while executing a parallel distributed query. If not enabled, the executor

might choose to use fewer connections to optimize overall query execution throughput. Internally, setting this parameter to `true` will end up using one connection per task. The default value is `false`.

One place where this is useful is in a transaction whose first query is lightweight and requires few connections, while a subsequent query would benefit from more connections. citus decides how many connections to use in a transaction based on the first statement, which can throttle other queries unless we use the configuration parameter to provide a hint.

The example below shows how to set this parameter:

```
BEGIN;
-- Add this hint
SET citus.force_max_query_parallelization TO ON;

-- A lightweight query that doesn't require many connections
SELECT count(*) FROM table WHERE filter = x;

-- A query that benefits from more connections, and can obtain
-- them since we forced max parallelization above
SELECT ... very .. complex .. SQL;
COMMIT;
```

`citus.explain_all_tasks` (`boolean`)

By default, citus shows the output of a single arbitrary task when running the `EXPLAIN` command on a distributed query. In most cases, the `EXPLAIN` output will be similar across tasks. Occasionally, some of the tasks will be planned differently or have much higher execution times. In those cases, it can be useful to enable this parameter, after which the `EXPLAIN` output will include all tasks. This may cause the `EXPLAIN` to take longer.

`citus.explain_analyze_sort_method` (`enum`)

Determines the sort method of the tasks in the output of `EXPLAIN ANALYZE`. The following values are supported:

- `execution-time` — sort by execution time.
- `taskId` — sort by task ID.

J.5.8. Administer

J.5.8.1. Cluster Management

In this section, we discuss how you can add or remove nodes from your citus cluster and how you can deal with node failures.

> **Note**
>
> To make moving shards across nodes or re-replicating shards on failed nodes easier, citus supports fully online shard rebalancing. We discuss briefly the functions provided by the shard rebalancer when relevant in the sections below. You can learn more about these functions, their arguments, and usage in the Cluster Management And Repair Functions section.

J.5.8.1.1. Choosing Cluster Size

This section explores configuration settings for running a cluster in production.

J.5.8.1.1.1. Shard Count

Choosing the shard count for each distributed table is a balance between the flexibility of having more shards and the overhead for query planning and execution across them. If you decide to change the shard count of a table after distributing, you can use the alter_distributed_table function.

Multi-Tenant SaaS Use Case

The optimal choice varies depending on your access patterns for the data. For instance, in the multi-tenant SaaS database use case we recommend choosing between 32 and 128 shards. For smaller workloads, say <100GB, you could start with 32 shards and for larger workloads you could choose 64 or 128 shards. This means that you have the leeway to scale from 32 to 128 worker machines.

Real-Time Analytics Use Case

In the real-time analytics use case, shard count should be related to the total number of cores on the workers. To ensure maximum parallelism, you should create enough shards on each node such that there is at least one shard per CPU core. We typically recommend creating a high number of initial shards, e.g. 2x or 4x the number of current CPU correspond. This allows for future scaling if you add more workers and CPU cores.

However, keep in mind that for each query citus opens one database connection per shard, and these connections are limited. Be careful to keep the shard count small enough that distributed queries will not often have to wait for a connection. Put another way, the connections needed, `(max concurrent queries * shard count)`, should generally not exceed the total connections possible in the system, `(number of workers * max_connections per worker)`.

J.5.8.1.2. Initial Hardware Size

The size of a cluster, in terms of number of nodes and their hardware capacity, is easy to change. However, you still need to choose an initial size for a new cluster. Here are some tips for a reasonable initial cluster size.

J.5.8.1.2.1. Multi-Tenant SaaS Use Case

For those migrating to citus from an existing single-node database instance, we recommend choosing a cluster where the number of worker cores and RAM in total equals that of the original instance. In such scenarios we have seen 2-3x performance improvements because sharding improves resource utilization, allowing smaller indices, etc.

The coordinator node needs less memory than workers, so you can choose a compute-optimized machine for running the coordinator. The number of cores required depends on your existing workload (write/read throughput).

J.5.8.1.2.2. Real-Time Analytics Use Case

Total cores: when working data fits in RAM, you can expect a linear performance improvement on citus proportional to the number of worker cores. To determine the right number of cores for your needs, consider the current latency for queries in your single-node database and the required latency in citus. Divide current latency by desired latency, and round the result.

Worker RAM: the best case would be providing enough memory that the majority of the working set fits in memory. The type of queries your application uses affect memory requirements. You can run `EXPLAIN ANALYZE` on a query to determine how much memory it requires.

J.5.8.1.3. Scaling the Cluster

citus logical sharding based architecture allows you to scale out your cluster without any downtime. This section describes how you can add more nodes to your citus cluster in order to improve query performance / scalability.

J.5.8.1.3.1. Adding a Worker

citus stores all the data for distributed tables on the worker nodes. Hence, if you want to scale out your cluster by adding more computing power, you can do so by adding a worker.

To add a new node to the cluster, you first need to add the DNS name or IP address of that node and port (on which Postgres Pro is running) in the pg_dist_node catalog table. You can do so using the citus_add_node function. Example:

```
SELECT * from citus_add_node('node-name', 5432);
```

The new node is available for shards of new distributed tables. Existing shards will stay where they are unless redistributed, so adding a new worker may not help performance without further steps.

> **Note**
>
> Also, new nodes synchronize citus metadata upon creation. By default, the sync happens inside a single transaction for consistency. However, in a big cluster with large amounts of metadata, the transaction can run out of memory and fail. If you encounter this situation, you can choose a non-transactional metadata sync mode with the citus.metadata_sync_mode configuration parameter.

J.5.8.1.3.2. Rebalancing Shards Without Downtime

If you want to move existing shards to a newly added worker, citus provides the citus_rebalance_start function to make it easier. This function will distribute shards evenly among the workers.

The function is configurable to rebalance shards according to a number of strategies, to best match your database workload. See the function reference to learn which strategy to choose. Here is an example of rebalancing shards using the default strategy:

```
SELECT citus_rebalance_start();
```

Many products like multi-tenant SaaS applications cannot tolerate downtime, and rebalancing is able to honor this requirement. This means reads and writes from the application can continue with minimal interruption while data is being moved.

Parallel Rebalancing

This operation carries out multiple shard moves in a sequential order by default. There are some cases where you may prefer to rebalance faster at the expense of using more resources such as network bandwidth. In those situations, customers are able to configure a rebalance operation to perform a number of shard moves in parallel.

The citus.max_background_task_executors_per_node configuration parameter allows tasks such as shard rebalancing to operate in parallel. You can increase it from its default value of `1` as desired to boost parallelism.

```
ALTER SYSTEM SET citus.max_background_task_executors_per_node = 2;
SELECT pg_reload_conf();

SELECT citus_rebalance_start();
```

What are the typical use cases?

- Scaling out faster when adding new nodes to the cluster.
- Rebalancing the cluster faster to even out the utilization of nodes.

Corner Cases and Gotchas

The citus.max_background_task_executors_per_node configuration parameter limits the number of parallel task executors in general. Also, shards in the same colocation group will always move sequentially so parallelism may be limited by the number of colocation groups.

How it Works

citus shard rebalancing uses Postgres Pro logical replication to move data from the old shard (called the “publisher” in replication terms) to the new (the “subscriber”). Logical replication allows application reads and writes to continue uninterrupted while copying shard data. citus puts a brief write-lock on a shard only during the time it takes to update metadata to promote the subscriber shard as active.

As the Postgres Pro documentation explains, the source needs a *replica identity* configured:

A published table must have a “replica identity” configured in order to be able to replicate `UPDATE` and `DELETE` operations, so that appropriate rows to update or delete can be identified on the subscriber side. By default, this is the primary key, if there is one. Another unique index (with certain additional requirements) can also be set to be the replica identity.

In other words, if your distributed table has a primary key defined then it is ready for shard rebalancing with no extra work. However, if it does not have a primary key or an explicitly defined replica identity, then attempting to rebalance it will cause an error. Here is how to fix it.

First, does the table have a unique index?

If the table to be replicated already has a unique index, which includes the distribution column, then choose that index as a replica identity:

```
-- Supposing my_table has unique index my_table_idx
-- which includes distribution column

ALTER TABLE my_table REPLICA IDENTITY
  USING INDEX my_table_idx;
```

> **Note**
>
> While `REPLICA IDENTITY USING INDEX` is fine, we recommend **against** adding `REPLICA IDENTITY FULL` to a table. This setting would result in each `UPDATE`/ `DELETE` doing a full-table-scan on the subscriber side to find the tuple with those rows. In our testing we have found this to result in worse performance than even solution four below.

Otherwise, can you add a primary key?

Add a primary key to the table. If the desired key happens to be the distribution column, then it's quite easy, just add the constraint. Otherwise, a primary key with a non-distribution column must be composite and contain the distribution column too.

J.5.8.1.3.3. Adding a Coordinator

The citus coordinator only stores metadata about the table shards and does not store any data. This means that all the computation is pushed down to the workers and the coordinator does only final aggregations on the result of the workers. Therefore, it is not very likely that the coordinator becomes a bottleneck for read performance. Also, it is easy to boost up the coordinator by shifting to a more powerful machine.

However, in some write-heavy use cases where the coordinator becomes a performance bottleneck, you can add another coordinator. As the metadata tables are small (typically a few MBs in size), it is possible to copy over the metadata onto another node and sync it regularly. Once this is done, users can send their queries to any coordinator and scale out performance.

J.5.8.1.4. Dealing With Node Failures

In this subsection, we discuss how you can deal with node failures without incurring any downtime on your citus cluster.

J.5.8.1.4.1. Worker Node Failures

citus uses Postgres Pro streaming replication, allowing it to tolerate worker-node failures. This option replicates entire worker nodes by continuously streaming their WAL records to a standby. You can configure streaming replication on-premise yourself by consulting the Streaming Replication section.

J.5.8.1.4.2. Coordinator Node Failures

The citus coordinator maintains metadata tables to track all of the cluster nodes and the locations of the database shards on those nodes. The metadata tables are small (typically a few MBs in size) and

do not change very often. This means that they can be replicated and quickly restored if the node ever experiences a failure. There are several options on how users can deal with coordinator failures.

- **Use Postgres Pro streaming replication**. You can use Postgres Pro streaming replication feature to create a hot standby of the coordinator. Then, if the primary coordinator node fails, the standby can be promoted to the primary automatically to serve queries to your cluster. For details on setting this up, please refer to the Streaming Replication section.
- **Use backup tools**. Since the metadata tables are small, users can use EBS volumes, or Postgres Pro backup tools to backup the metadata. Then, they can easily copy over that metadata to new nodes to resume operation.

J.5.8.1.5. Tenant Isolation

J.5.8.1.5.1. Row-Based Sharding

citus places table rows into worker shards based on the hashed value of the rows' distribution column. Multiple distribution column values often fall into the same shard. In the citus multi-tenant use case this means that tenants often share shards.

However, sharing shards can cause resource contention when tenants differ drastically in size. This is a common situation for systems with a large number of tenants — we have observed that the size of tenant data tend to follow a Zipfian distribution as the number of tenants increases. This means there are a few very large tenants, and many smaller ones. To improve resource allocation and make guarantees of tenant QoS it is worthwhile to move large tenants to dedicated nodes.

citus provides the tools to isolate a tenant on a specific node. This happens in two phases: firstly, isolating the tenant's data to a new dedicated shard, then moving the shard to the desired node. To understand the process, it helps to know precisely how rows of data are assigned to shards.

Every shard is marked in citus metadata with the range of hashed values it contains (more info in the reference for the pg_dist_shard table). The isolate_tenant_to_new_shard function moves a tenant into a dedicated shard in three steps:

1. Creates a new shard for `table_name`, which includes rows whose distribution column has value `tenant_id` and excludes all other rows.
2. Moves the relevant rows from their current shard to the new shard.
3. Splits the old shard into two with hash ranges that abut the excision above and below.

Furthermore, the function takes the `CASCADE` option, which isolates the tenant rows of not just `table_name` but of all tables co-located with it. Here is an example:

```
-- This query creates an isolated shard for the given tenant_id and
-- returns the new shard id.

-- General form:

SELECT isolate_tenant_to_new_shard('table_name', tenant_id);

-- Specific example:

SELECT isolate_tenant_to_new_shard('lineitem', 135);

-- If the given table has co-located tables, the query above errors out and
-- advises to use the CASCADE option

SELECT isolate_tenant_to_new_shard('lineitem', 135, 'CASCADE');
```

Output:

```
┌─────────────────────────────┐
│ isolate_tenant_to_new_shard │
```

```
├──────────────────────────────────┤
│                           102240 │
└──────────────────────────────────┘
```

The new shard(s) are created on the same node as the shard(s) from which the tenant was removed. For true hardware isolation they can be moved to a separate node in the citus cluster. As mentioned, the isolate_tenant_to_new_shard function returns the newly created shard ID, and this ID can be used to move the shard:

J.5.8.1.5.2. Schema-Based Sharding

In schema-based sharding, the act of isolating a tenant is not required as by definition each tenant already resides in its own schema. The only thing that is needed is obtaining a shard identifier for a schema to perform a move.

First find the colocation ID of the schema you want to move.

```
SELECT * FROM citus_schemas;
```

```
schema_name  | colocation_id | schema_size | schema_owner
-------------+---------------+-------------+--------------
user_service |             1 | 0 bytes     | user_service
time_service |             2 | 0 bytes     | time_service
ping_service |             3 | 0 bytes     | ping_service
a            |             4 | 128 kB      | citus
b            |             5 | 32 kB       | citus
with_data    |            11 | 6408 kB     | citus
(6 rows)
```

The next step is to query `citus_shards`, we will use co-location identifier `11` from the output above:

```
SELECT * FROM citus_shards where colocation_id = 11;
```

```
  table_name    | shardid |       shard_name       | citus_table_type | colocation_id |
 nodename  | nodeport | shard_size
-----------------+---------+------------------------+------------------+---------------
+-----------+----------+------------
with_data.test  |  102180 | with_data.test_102180  | schema           |            11 |
 localhost |     9702 |     647168
with_data.test2 |  102183 | with_data.test2_102183 | schema           |            11 |
 localhost |     9702 |    5914624
(2 rows)
```

You can pick any `shardid` from the output as making the move will also propagate to all co-located tables, which in case of schema-based sharding means moving all tables within the schema.

J.5.8.1.5.3. Make the Move

Knowing the shard ID that denotes the tenant, you can execute the move:

```
-- Find the node currently holding the new shard
SELECT nodename, nodeport
  FROM citus_shards
 WHERE shardid = 102240;

-- List the available worker nodes that could hold the shard
SELECT * FROM master_get_active_worker_nodes();

-- Move the shard to your choice of worker
-- (it will also move any shards created with the CASCADE option)
SELECT citus_move_shard_placement(
  102240,
  'source_host', source_port,
```

```
  'dest_host', dest_port);
```

Note that the citus_move_shard_placement function will also move any shards which are co-located with the specified one, to preserve their co-location.

J.5.8.1.6. Viewing Query Statistics

When administering a citus cluster it is useful to know what queries users are running, which nodes are involved, and which execution method citus is using for each query. The extension records query statistics in a metadata view called citus_stat_statements, named analogously to Postgres Pro pg_stat_statements. Whereas `pg_stat_statements` stores info about query duration and I/O, `citus_stat_statements` stores info about citus execution methods and shard partition keys (when applicable).

citus requires the pg_stat_statements extension to be installed in order to track query statistics. On a self-hosted Postgres Pro instance load the extension in `postgresql.conf` via `shared_preload_libraries`, then create the extension in SQL:

```
CREATE EXTENSION pg_stat_statements;
```

Let's see how this works. Assume we have a table called `foo` that is hash-distributed by its `id` column.

```
-- Create and populate distributed table
CREATE TABLE foo ( id int );
SELECT create_distributed_table('foo', 'id');

INSERT INTO foo SELECT generate_series(1,100);
```

We will run two more queries and `citus_stat_statements` will show how citus chooses to execute them.

```
-- Counting all rows executes on all nodes, and sums
-- the results on the coordinator
SELECT count(*) FROM foo;

-- Specifying a row by the distribution column routes
-- execution to an individual node
SELECT * FROM foo WHERE id = 42;
```

To find how these queries were executed, ask the stats table:

```
SELECT * FROM citus_stat_statements;
```

Results:

```
-[ RECORD 1 ]-+----------------------------------------------
queryid       | -6844578505338488014
userid        | 10
dbid          | 13340
query         | SELECT count(*) FROM foo;
executor      | adaptive
partition_key |
calls         | 1
-[ RECORD 2 ]-+----------------------------------------------
queryid       | 185453597994293667
userid        | 10
dbid          | 13340
query         | INSERT INTO foo SELECT generate_series($1,$2)
executor      | insert-select
partition_key |
calls         | 1
-[ RECORD 3 ]-+----------------------------------------------
queryid       | 1301170733886649828
userid        | 10
dbid          | 13340
```

```
query          | SELECT * FROM foo WHERE id = $1
executor       | adaptive
partition_key | 42
calls          | 1
```

We can see that citus uses the adaptive executor most commonly to run queries. This executor fragments the query into constituent queries to run on relevant nodes and combines the results on the coordinator node. In the case of the second query (filtering by the distribution column `id = $1`), citus determined that it needed the data from just one node. Lastly, we can see that the `INSERT INTO foo SELECT…` statement ran with the `insert-select` executor that provides flexibility to run these kind of queries.

J.5.8.1.6.1. Tenant-Level Statistics

So far the information in this view does not give us anything we could not already learn by running the `EXPLAIN` command for a given query. However, in addition to getting information about individual queries, the citus_stat_statements view allows us to answer questions such as “what percentage of queries in the cluster are scoped to a single tenant?”

```
SELECT sum(calls),
       partition_key IS NOT NULL AS single_tenant
FROM citus_stat_statements
GROUP BY 2;
```

```
.
 sum | single_tenant
-----+---------------
   2 | f
   1 | t
```

In a multi-tenant database, for instance, we would expect the vast majority of queries to be single tenant. Seeing too many multi-tenant queries may indicate that queries do not have the proper filters to match a tenant, and are using unnecessary resources.

To investigate which tenants in particular are most active, you can use the citus_stat_tenants view.

J.5.8.1.6.2. Statistics Expiration

The pg_stat_statements view limits the number of statements it tracks and the duration of its records. Because the citus_stat_statements table tracks a strict subset of the queries in `pg_stat_statements`, a choice of equal limits for the two views would cause a mismatch in their data retention. Mismatched records can cause joins between the views to behave unpredictably.

There are three ways to help synchronize the views, and all three can be used together.

1. Have the maintenance daemon periodically sync the citus and Postgres Pro statistics. The citus.stat_statements_purge_interval configuration parameter sets time in seconds for the sync. A value of `0` disables periodic syncs.
2. Adjust the number of entries in `citus_stat_statements`. The citus.stat_statements_max configuration parameter removes old entries when new ones cross the threshold. The default value is `50000`, and the highest allowable value is `10000000`. Note that each entry costs about 140 bytes in shared memory so set the value wisely.
3. Increase pg_stat_statements.max. Its default value is `5000` and could be increased to `10000`, `20000` or even `50000` without much overhead. This is most beneficial when there is more local (i.e. coordinator) query workload.

> **Note**
>
> Changing `pg_stat_statements.max` or `citus.stat_statements_max` requires restarting the Postgres Pro service. Changing `citus.stat_statements_purge_interval`, on the other hand, will come into effect with a call to the pg_reload_conf function.

J.5.8.1.7. Resource Conservation

J.5.8.1.7.1. Limiting Long-Running Queries

Long running queries can hold locks, queue up WAL, or just consume a lot of system resources, so in a production environment it is good to prevent them from running too long. You can set the statement_timeout parameter on the coordinator and workers to cancel queries that run too long.

```
-- Limit queries to five minutes
ALTER DATABASE citus
  SET statement_timeout TO 300000;
SELECT run_command_on_workers($cmd$
  ALTER DATABASE citus
    SET statement_timeout TO 300000;
$cmd$);
```

The timeout is specified in milliseconds.

To customize the timeout per query, use `SET LOCAL` in a transaction:

```
BEGIN;
-- this limit applies to just the current transaction
SET LOCAL statement_timeout TO 300000;

-- ...
COMMIT;
```

J.5.8.1.8. Security

J.5.8.1.8.1. Connection Management

> **Note**
>
> The traffic between the different nodes in the cluster is encrypted for new installations. This is done by using TLS with self-signed certificates. This means that this **does not protect against man-in-the-middle attacks**. This only protects against passive eavesdropping on the network.
>
> Clusters originally created with citus do not have any network encryption enabled between nodes (even if upgraded later). To set up self-signed TLS on this type of installation follow the steps in the Creating Certificates section together with the citus specific settings described here, i.e. changing the citus.node_conninfo parameter to `sslmode=require`. This setup should be done on the coordinator and workers.

When citus nodes communicate with one another they consult a table with connection credentials. This gives the database administrator flexibility to adjust parameters for security and efficiency.

To set non-sensitive libpq connection parameters to be used for all node connections, update the `citus.node_conninfo` configuration parameter:

```
-- key=value pairs separated by spaces.
-- For example, ssl options:

ALTER SYSTEM SET citus.node_conninfo =
  'sslrootcert=/path/to/citus-ca.crt sslcrl=/path/to/citus-ca.crl sslmode=verify-full';
```

There is a whitelist of options that the citus.node_conninfo configuration parameter accepts. The default value is `sslmode=require`, which prevents unencrypted communication between nodes. If your cluster was originally created with citus, the value will be `sslmode=prefer`. After setting up self-signed certificates on all nodes it is recommended to change this setting to `sslmode=require`.

After changing this setting it is important to reload the Postgres Pro configuration. Even though the changed setting might be visible in all sessions, the setting is only consulted by citus when new connections are established. When a reload signal is received, citus marks all existing connections to be closed which causes a reconnect after running transactions have been completed.

```
SELECT pg_reload_conf();
```

```
-- Only superusers can access this table

-- Add a password for user jdoe
INSERT INTO pg_dist_authinfo
  (nodeid, rolename, authinfo)
VALUES
  (123, 'jdoe', 'password=abc123');
```

After this `INSERT`, any query needing to connect to node `123` as the user `jdoe` will use the supplied password. To learn more, see the section about the `pg_dist_authinfo` table.

```
-- Update user jdoe to use certificate authentication
UPDATE pg_dist_authinfo
SET authinfo = 'sslcert=/path/to/user.crt sslkey=/path/to/user.key'
WHERE nodeid = 123 AND rolename = 'jdoe';
```

This changes the user from using a password to use a certificate and keyfile while connecting to node 123 instead. Make sure the user certificate is signed by a certificate that is trusted by the worker you are connecting to and authentication settings on the worker allow for certificate based authentication. Full documentation on how to use client certificates can be found in the Client Certificates section.

Changing the `pg_dist_authinfo` table does not force any existing connection to reconnect.

J.5.8.1.8.2. Setup Certificate Authority Signed Certificates

This section assumes you have a trusted Certificate Authority that can issue server certificates to you for all nodes in your cluster. It is recommended to work with the security department in your organization to prevent key material from being handled incorrectly. This guide covers only citus specific configuration that needs to be applied, not best practices for PKI management.

For all nodes in the cluster you need to get a valid certificate signed by the *same Certificate Authority*. The following machine-specific files are assumed to be available on every machine:

- `/path/to/server.key` — Server Private Key
- `/path/to/server.crt` — Server Certificate or Certificate Chain for Server Key, signed by trusted Certificate Authority

Next to these machine-specific files you need these cluster or Certificate Authority wide files available:

- `/path/to/ca.crt` — Certificate of the Certificate Authority
- `/path/to/ca.crl` — Certificate Revocation List of the Certificate Authority

> **Note**
>
> The Certificate Revocation List is likely to change over time. Work with your security department to set up a mechanism to update the revocation list on to all nodes in the cluster in a timely manner. A reload of every node in the cluster is required after the revocation list has been updated.

Once all files are in place on the nodes, the following settings need to be configured in the Postgres configuration file:

```
# The following settings allow the postgres server to enable ssl, and
# configure the server to present the certificate to clients when
# connecting over tls/ssl
```

```
ssl = on
ssl_key_file = '/path/to/server.key'
ssl_cert_file = '/path/to/server.crt'

# This will tell citus to verify the certificate of the server it is connecting to
citus.node_conninfo = 'sslmode=verify-full sslrootcert=/path/to/ca.crt sslcrl=/path/to/
ca.crl'
```

After changing, reload the configuration to apply these changes. Also, adjusting citus.local_hostname may be required for proper functioning with `sslmode=verify-full`.

Depending on the policy of the Certificate Authority used you might need or want to change `sslmode=verify-full` in citus.node_conninfo to `sslmode=verify-ca`. For the difference between the two settings, consult the SSL Mode Descriptions section.

Lastly, to prevent any user from connecting via an un-encrypted connection, changes need to be made to `pg_hba.conf`. Many Postgres Pro installations will have entries allowing `host` connections which allow SSL/TLS connections as well as plain TCP connections. By replacing all `host` entries with `hostssl` entries, only encrypted connections will be allowed to authenticate to Postgres Pro. For full documentation on these settings take a look at the section about the `pg_hba.conf` file.

> **Note**
>
> When a trusted Certificate Authority is not available, one can create their own via a self-signed root certificate. This is non-trivial and the developer or operator should seek guidance from their security team when doing so.

To verify the connections from the coordinator to the workers are encrypted you can run the following query. It will show the SSL/TLS version used to encrypt the connection that the coordinator uses to talk to the worker:

```
SELECT run_command_on_workers($$
  SELECT version FROM pg_stat_ssl WHERE pid = pg_backend_pid()
$$);
```

```
┌─────────────────────────────────┐
│    run_command_on_workers      │
├─────────────────────────────────┤
│ (localhost,9701,t,TLSv1.2)     │
│ (localhost,9702,t,TLSv1.2)     │
└─────────────────────────────────┘
(2 rows)
```

J.5.8.1.8.3. Increasing Worker Security

For your convenience getting started, our multi-node installation instructions direct you to set up the `pg_hba.conf` on the workers with its authentication method set to `trust` for local network connections. However, you might desire more security.

To require that all connections supply a hashed password, update the Postgres Pro `pg_hba.conf` on every worker node with something like this:

```
# Require password access and a ssl/tls connection to nodes in the local
# network. The following ranges correspond to 24, 20, and 16-bit blocks
# in Private IPv4 address spaces.
hostssl    all             all             10.0.0.0/8              md5

# Require passwords and ssl/tls connections when the host connects to
# itself as well.
hostssl    all             all             127.0.0.1/32            md5
```

```
hostssl    all             all             ::1/128                 md5
```

The coordinator node needs to know roles' passwords in order to communicate with the workers. In citus the authentication information has to be maintained in the .pgpass file. Edit the file in the Postgres Pro user home directory, with a line for each combination of worker address and role:

```
hostname:port:database:username:password
```

Sometimes workers need to connect to one another, such as during repartition joins. Thus each worker node requires a copy of the `.pgpass` file as well.

J.5.8.1.8.4. Row-Level Security

Postgres Pro row-level security policies restrict, on a per-user basis, which rows can be returned by normal queries or inserted, updated, or deleted by data modification commands. This can be especially useful in a multi-tenant citus cluster because it allows individual tenants to have full SQL access to the database while hiding each tenant's information from other tenants.

We can implement the separation of tenant data by using a naming convention for database roles that ties into table row-level security policies. We will assign each tenant a database role in a numbered sequence: `tenant_1`, `tenant_2`, etc. Tenants will connect to citus using these separate roles. Row-level security policies can compare the role name to values in the `tenant_id` distribution column to decide whether to allow access.

Here is how to apply the approach on a simplified events table distributed by `tenant_id`. First create the roles `tenant_1` and `tenant_2`. Then run the following as an administrator:

```
CREATE TABLE events(
  tenant_id int,
  id int,
  type text
);

SELECT create_distributed_table('events','tenant_id');

INSERT INTO events VALUES (1,1,'foo'), (2,2,'bar');

-- Assumes that roles tenant_1 and tenant_2 exist
GRANT select, update, insert, delete
  ON events TO tenant_1, tenant_2;
```

As it stands, anyone with `SELECT` permissions for this table can see both rows. Users from either tenant can see and update the row of the other tenant. We can solve this with row-level table security policies.

Each policy consists of two clauses: `USING` and `WITH CHECK`. When a user tries to read or write rows, the database evaluates each row against these clauses. Existing table rows are checked against the expression specified in `USING`, while new rows that would be created via `INSERT` or `UPDATE` are checked against the expression specified in `WITH CHECK`.

```
-- First a policy for the system admin "citus" user
CREATE POLICY admin_all ON events
  TO citus           -- apply to this role
  USING (true)       -- read any existing row
  WITH CHECK (true); -- insert or update any row

-- Next a policy which allows role "tenant_<n>" to
-- access rows where tenant_id = <n>
CREATE POLICY user_mod ON events
  USING (current_user = 'tenant_' || tenant_id::text);
  -- Lack of CHECK means same condition as USING
```

```
-- Enforce the policies
ALTER TABLE events ENABLE ROW LEVEL SECURITY;
```

Now roles `tenant_1` and `tenant_2` get different results for their queries:

Connected as `tenant_1`:

```
SELECT * FROM events;
```

```
┌─────────────┬────┬──────┐
│ tenant_id │ id │ type │
├─────────────┼────┼──────┤
│           1 │  1 │ foo  │
└─────────────┴────┴──────┘
```

Connected as `tenant_2`:

```
SELECT * FROM events;
```

```
┌─────────────┬────┬──────┐
│ tenant_id │ id │ type │
├─────────────┼────┼──────┤
│           2 │  2 │ bar  │
└─────────────┴────┴──────┘
```

```
INSERT INTO events VALUES (3,3,'surprise');
/*
ERROR:  new row violates row-level security policy for table "events_102055"
*/
```

J.5.8.1.9. Postgres Pro extensions

citus provides distributed functionality by extending Postgres Pro using the hook and extension APIs. This allows users to benefit from the features that come with the rich Postgres Pro ecosystem. These features include, but are not limited to, support for a wide range of data types (including semi-structured data types like `jsonb` and `hstore`), operators and functions, full text search, and other extensions such as *PostGIS* and *HyperLogLog*. Further, proper use of the extension APIs enable compatibility with standard Postgres Pro tools such as *pgAdmin* and pg_upgrade.

As citus is an extension which can be installed on any Postgres Pro instance, you can directly use other extensions such as hstore, hll, or PostGIS with citus. However, there is one thing to keep in mind. While including other extensions in `shared_preload_libraries`, you should make sure that citus is the first extension.

There are several extensions, which may be useful when working with citus:

- *cstore_fdw* — columnar store for analytics. The columnar nature delivers performance by reading only relevant data from disk, and it may compress data 6x-10x to reduce space requirements for data archival.
- *pg_cron* — run periodic jobs directly from the database.
- *topn* — returns the top values in a database according to some criteria. Uses an approximation algorithm to provide fast results with modest compute and memory resources.
- *hll* — HyperLogLog data structure as a native data type. It is a fixed-size, set-like structure used for distinct value counting with tunable precision.

J.5.8.1.10. Creating a New Database

Each Postgres Pro server can hold multiple databases. However, new databases do not inherit the extensions of any others; all desired extensions must be added afresh. To run citus on a new database, you will need to create the database on the coordinator and workers, create the citus extension within that database, and register the workers in the coordinator database.

Connect to each of the worker nodes and run:

```
-- On every worker node

CREATE DATABASE newbie;
\c newbie
CREATE EXTENSION citus;
```

Then, on the coordinator:

```
CREATE DATABASE newbie;
\c newbie
CREATE EXTENSION citus;

SELECT * from citus_add_node('node-name', 5432);
SELECT * from citus_add_node('node-name2', 5432);
-- ... for all of them
```

Now the new database will be operating as another citus cluster.

J.5.8.2. Table Management

J.5.8.2.1. Determining Table and Relation Size

The usual way to find table sizes in Postgres Pro, pg_total_relation_size, drastically under-reports the size of distributed tables. All this function does on a citus cluster is reveal the size of tables on the coordinator node. In reality the data in distributed tables lives on the worker nodes (in shards), not on the coordinator. A true measure of distributed table size is obtained as a sum of shard sizes. citus provides helper functions to query this information.

Function	Returns
citus_relation_size	• Size of actual data in table (the "main fork") • A relation can be the name of a table or an index
citus_table_size	• Output of the `citus_relation_size` plus: • size of the free space map • size of the visibility map
citus_total_relation_size	• Output of the `citus_table_size` plus: • size of indices

These functions are analogous to three of the standard Postgres Pro object size functions, with the additional note that if they cannot connect to a node, they error out.

Here is an example of using one of the helper functions to list the sizes of all distributed tables:

```
SELECT logicalrelid AS name,
       pg_size_pretty(citus_table_size(logicalrelid)) AS size
  FROM pg_dist_partition;
```

Output:

```
┌────────────────┬────────┐
│      name      │  size  │
├────────────────┼────────┤
│ github_users   │ 39 MB  │
│ github_events  │ 37 MB  │
└────────────────┴────────┘
```

J.5.8.2.2. Vacuuming Distributed Tables

In Postgres Pro (and other MVCC databases), an `UPDATE` or `DELETE` of a row does not immediately remove the old version of the row. The accumulation of outdated rows is called bloat and must be cleaned to

avoid decreased query performance and unbounded growth of disk space requirements. Postgres Pro runs a process called the auto-vacuum daemon that periodically vacuums (removes) outdated rows.

It is not just user queries which scale in a distributed database, vacuuming does too. In Postgres Pro big busy tables have great potential to bloat, both from lower sensitivity to Postgres Pro vacuum scale factor parameter, and generally because of the extent of their row churn. Splitting a table into distributed shards means both that individual shards are smaller tables and that auto-vacuum workers can parallelize over different parts of the table on different machines. Ordinarily auto-vacuum can only run one worker per table.

Due to the above, auto-vacuum operations on a citus cluster are probably good enough for most cases. However, for tables with particular workloads, or companies with certain “safe” hours to schedule a vacuum, it might make more sense to manually vacuum a table rather than leaving all the work to auto-vacuum.

To vacuum a table, simply run this on the coordinator node:

```
VACUUM my_distributed_table;
```

Using vacuum against a distributed table will send the `VACUUM` command to every one of that table's placements (one connection per placement). This is done in parallel. All options are supported (including the *`table_and_columns`* list) except for `VERBOSE`. The `VACUUM` command also runs on the coordinator, and does so before any workers nodes are notified. Note that unqualified vacuum commands (i.e. those without a table specified) do not propagate to worker nodes.

J.5.8.2.3. Analyzing Distributed Tables

Postgres Pro `ANALYZE` command collects statistics about the contents of tables in the database. Subsequently, the query planner uses these statistics to help determine the most efficient execution plans for queries.

The auto-vacuum daemon, discussed in the previous section, will automatically issue `ANALYZE` commands whenever the content of a table has changed sufficiently. The daemon schedules `ANALYZE` strictly as a function of the number of rows inserted or updated; it has no knowledge of whether that will lead to meaningful statistical changes. Administrators might prefer to manually schedule `ANALYZE` operations instead, to coincide with statistically meaningful table changes.

To analyze a table, run this on the coordinator node:

```
ANALYZE my_distributed_table;
```

citus propagates the `ANALYZE` command to all worker node placements.

J.5.8.2.4. Columnar Storage

citus provides append-only columnar table storage for analytic and data warehousing workloads. When columns (rather than rows) are stored contiguously on disk, data becomes more compressible, and queries can request a subset of columns more quickly.

J.5.8.2.4.1. Usage

To use columnar storage, specify `USING columnar` when creating a table:

```
CREATE TABLE contestant (
    handle TEXT,
    birthdate DATE,
    rating INT,
    percentile FLOAT,
    country CHAR(3),
    achievements TEXT[]
) USING columnar;
```

You can also convert between row-based (`heap`) and `columnar` storage.

```
-- Convert to row-based (heap) storage
SELECT alter_table_set_access_method('contestant', 'heap');

-- Convert to columnar storage (indexes will be dropped)
SELECT alter_table_set_access_method('contestant', 'columnar');
```

citus converts rows to columnar storage in “stripes” during insertion. Each stripe holds one transaction's worth of data, or 150000 rows, whichever is less. (The stripe size and other parameters of a columnar table can be changed with the alter_columnar_table_set function.)

For example, the following statement puts all five rows into the same stripe, because all values are inserted in a single transaction:

```
-- Insert these values into a single columnar stripe

INSERT INTO contestant VALUES
  ('a','1990-01-10',2090,97.1,'XA','{a}'),
  ('b','1990-11-01',2203,98.1,'XA','{a,b}'),
  ('c','1988-11-01',2907,99.4,'XB','{w,y}'),
  ('d','1985-05-05',2314,98.3,'XB','{}'),
  ('e','1995-05-05',2236,98.2,'XC','{a}');
```

It is best to make large stripes when possible, because citus compresses columnar data separately per stripe. We can see facts about our columnar table like compression rate, number of stripes, and average rows per stripe by using `VACUUM VERBOSE`:

```
VACUUM VERBOSE contestant;
```

```
INFO:  statistics for "contestant":
storage id: 10000000000
total file size: 24576, total data size: 248
compression rate: 1.31x
total row count: 5, stripe count: 1, average rows per stripe: 5
chunk count: 6, containing data for dropped columns: 0, zstd compressed: 6
```

The output shows that citus used the `zstd` compression algorithm to obtain 1.31x data compression. The compression rate compares the size of inserted data as it was staged in memory against the size of that data compressed in its eventual stripe.

Because of how it is measured, the compression rate may or may not match the size difference between row and columnar storage for a table. The only way to truly find that difference is to construct a row and columnar table that contain the same data and compare.

J.5.8.2.4.2. Measuring Compression

Let's create a new example with more data to benchmark the compression savings.

```
-- First a wide table using row storage
CREATE TABLE perf_row(
  c00 int8, c01 int8, c02 int8, c03 int8, c04 int8, c05 int8, c06 int8, c07 int8, c08
 int8, c09 int8,
  c10 int8, c11 int8, c12 int8, c13 int8, c14 int8, c15 int8, c16 int8, c17 int8, c18
 int8, c19 int8,
  c20 int8, c21 int8, c22 int8, c23 int8, c24 int8, c25 int8, c26 int8, c27 int8, c28
 int8, c29 int8,
  c30 int8, c31 int8, c32 int8, c33 int8, c34 int8, c35 int8, c36 int8, c37 int8, c38
 int8, c39 int8,
  c40 int8, c41 int8, c42 int8, c43 int8, c44 int8, c45 int8, c46 int8, c47 int8, c48
 int8, c49 int8,
  c50 int8, c51 int8, c52 int8, c53 int8, c54 int8, c55 int8, c56 int8, c57 int8, c58
 int8, c59 int8,
```

```
  c60 int8, c61 int8, c62 int8, c63 int8, c64 int8, c65 int8, c66 int8, c67 int8, c68
 int8, c69 int8,
  c70 int8, c71 int8, c72 int8, c73 int8, c74 int8, c75 int8, c76 int8, c77 int8, c78
 int8, c79 int8,
  c80 int8, c81 int8, c82 int8, c83 int8, c84 int8, c85 int8, c86 int8, c87 int8, c88
 int8, c89 int8,
  c90 int8, c91 int8, c92 int8, c93 int8, c94 int8, c95 int8, c96 int8, c97 int8, c98
 int8, c99 int8
);

-- Next a table with identical columns using columnar storage
CREATE TABLE perf_columnar(LIKE perf_row) USING COLUMNAR;
```

Fill both tables with the same large dataset:

```
INSERT INTO perf_row
  SELECT
    g % 00500, g % 01000, g % 01500, g % 02000, g % 02500, g % 03000, g % 03500, g %
 04000, g % 04500, g % 05000,
    g % 05500, g % 06000, g % 06500, g % 07000, g % 07500, g % 08000, g % 08500, g %
 09000, g % 09500, g % 10000,
    g % 10500, g % 11000, g % 11500, g % 12000, g % 12500, g % 13000, g % 13500, g %
 14000, g % 14500, g % 15000,
    g % 15500, g % 16000, g % 16500, g % 17000, g % 17500, g % 18000, g % 18500, g %
 19000, g % 19500, g % 20000,
    g % 20500, g % 21000, g % 21500, g % 22000, g % 22500, g % 23000, g % 23500, g %
 24000, g % 24500, g % 25000,
    g % 25500, g % 26000, g % 26500, g % 27000, g % 27500, g % 28000, g % 28500, g %
 29000, g % 29500, g % 30000,
    g % 30500, g % 31000, g % 31500, g % 32000, g % 32500, g % 33000, g % 33500, g %
 34000, g % 34500, g % 35000,
    g % 35500, g % 36000, g % 36500, g % 37000, g % 37500, g % 38000, g % 38500, g %
 39000, g % 39500, g % 40000,
    g % 40500, g % 41000, g % 41500, g % 42000, g % 42500, g % 43000, g % 43500, g %
 44000, g % 44500, g % 45000,
    g % 45500, g % 46000, g % 46500, g % 47000, g % 47500, g % 48000, g % 48500, g %
 49000, g % 49500, g % 50000
  FROM generate_series(1,50000000) g;

INSERT INTO perf_columnar
  SELECT
    g % 00500, g % 01000, g % 01500, g % 02000, g % 02500, g % 03000, g % 03500, g %
 04000, g % 04500, g % 05000,
    g % 05500, g % 06000, g % 06500, g % 07000, g % 07500, g % 08000, g % 08500, g %
 09000, g % 09500, g % 10000,
    g % 10500, g % 11000, g % 11500, g % 12000, g % 12500, g % 13000, g % 13500, g %
 14000, g % 14500, g % 15000,
    g % 15500, g % 16000, g % 16500, g % 17000, g % 17500, g % 18000, g % 18500, g %
 19000, g % 19500, g % 20000,
    g % 20500, g % 21000, g % 21500, g % 22000, g % 22500, g % 23000, g % 23500, g %
 24000, g % 24500, g % 25000,
    g % 25500, g % 26000, g % 26500, g % 27000, g % 27500, g % 28000, g % 28500, g %
 29000, g % 29500, g % 30000,
    g % 30500, g % 31000, g % 31500, g % 32000, g % 32500, g % 33000, g % 33500, g %
 34000, g % 34500, g % 35000,
    g % 35500, g % 36000, g % 36500, g % 37000, g % 37500, g % 38000, g % 38500, g %
 39000, g % 39500, g % 40000,
    g % 40500, g % 41000, g % 41500, g % 42000, g % 42500, g % 43000, g % 43500, g %
 44000, g % 44500, g % 45000,
```

```
    g % 45500, g % 46000, g % 46500, g % 47000, g % 47500, g % 48000, g % 48500, g %
 49000, g % 49500, g % 50000
  FROM generate_series(1,50000000) g;

VACUUM (FREEZE, ANALYZE) perf_row;
VACUUM (FREEZE, ANALYZE) perf_columnar;
```

For this data, you can see a compression ratio of better than 8X in the columnar table.

```
SELECT pg_total_relation_size('perf_row')::numeric/
       pg_total_relation_size('perf_columnar') AS compression_ratio;

.
 compression_ratio
--------------------
 8.0196135873627944
(1 row)
```

J.5.8.2.4.3. Example

Columnar storage works well with table partitioning. For example, see the Archiving with Columnar Storage section.

J.5.8.2.4.4. Gotchas

- Columnar storage compresses per stripe. Stripes are created per transaction, so inserting one row per transaction will put single rows into their own stripes. Compression and performance of single row stripes will be worse than a row table. Always insert in bulk to a columnar table.
- If you mess up and columnarize a bunch of tiny stripes, there is no way to repair the table. The only fix is to create a new columnar table and copy data from the original in one transaction:

  ```
  BEGIN;
  CREATE TABLE foo_compacted (LIKE foo) USING columnar;
  INSERT INTO foo_compacted SELECT * FROM foo;
  DROP TABLE foo;
  ALTER TABLE foo_compacted RENAME TO foo;
  COMMIT;
  ```

- Fundamentally non-compressible data can be a problem, although it can still be useful to use columnar so that less is loaded into memory when selecting specific columns.
- On a partitioned table with a mix of row and column partitions, updates must be carefully targeted or filtered to hit only the row partitions.
  - If the operation is targeted at a specific row partition (e.g. `UPDATE p2 SET i = i + 1`), it will succeed; if targeted at a specified columnar partition (e.g. `UPDATE p1 SET i = i + 1`), it will fail.
  - If the operation is targeted at the partitioned table and has a `WHERE` clause that excludes all columnar partitions (e.g. `UPDATE parent SET i = i + 1 WHERE timestamp = '2020-03-15'`), it will succeed.
  - If the operation is targeted at the partitioned table, but does not exclude all columnar partitions, it will fail; even if the actual data to be updated only affects row tables (e.g. `UPDATE parent SET i = i + 1 WHERE n = 300`).

J.5.8.2.4.5. Limitations

Future versions of citus will incrementally lift the current limitations:

- Append-only (no `UPDATE`/`DELETE` support)
- No space reclamation (e.g. rolled-back transactions may still consume disk space)
- Support for hash and btree indices only
- No index scans, or bitmap index scans

- No TID scan
- No sample scans
- No TOAST support (large values supported inline)
- No support for `ON CONFLICT` statements (except `DO NOTHING` actions with no target specified)
- No support for tuple locks (`SELECT ... FOR SHARE`, `SELECT ... FOR UPDATE`)
- No support for serializable isolation level
- Support for Postgres Pro server versions 12+ only
- No support for foreign keys, unique constraints, or exclusion constraints
- No support for logical decoding
- No support for intra-node parallel scans
- No support for `AFTER ... FOR EACH ROW` triggers
- No `UNLOGGED` columnar tables
- No `TEMPORARY` columnar tables

J.5.9. Troubleshoot

J.5.9.1. Query Performance Tuning

In this section, we describe how you can tune your citus cluster to get maximum performance. We begin by explaining how choosing the right distribution column affects performance. We then describe how you can first tune your database for high performance on one Postgres Pro server and then scale it out across all the CPUs in the cluster. In this section, we also discuss several performance related configuration parameters wherever relevant.

J.5.9.1.1. Table Distribution and Shards

The first step while creating a distributed table is choosing the right distribution column. This helps citus push down several operations directly to the worker shards and prune away unrelated shards, which lead to significant query speedups.

Typically, you should pick that column as the distribution column which is the most commonly used join key or on which most queries have filters. For filters, citus uses the distribution column ranges to prune away unrelated shards, ensuring that the query hits only those shards which overlap with the `WHERE` clause ranges. For joins, if the join key is the same as the distribution column, then citus executes the join only between those shards, which have matching / overlapping distribution column ranges. All these shard joins can be executed in parallel on the workers and hence are more efficient.

In addition, citus can push down several operations directly to the worker shards if they are based on the distribution column. This greatly reduces both the amount of computation on each node and the network bandwidth involved in transferring data across nodes.

Once you choose the right distribution column, you can then proceed to the next step, which is tuning worker node performance.

J.5.9.1.2. Postgres Pro Tuning

The citus coordinator partitions an incoming query into fragment queries and sends them to the workers for parallel processing. The workers are just extended Postgres Pro servers and they apply Postgres Pro standard planning and execution logic for these queries. So, the first step in tuning citus is tuning the Postgres Pro configuration parameters on the workers for high performance.

Tuning the parameters is a matter of experimentation and often takes several attempts to achieve acceptable performance. Thus it is best to load only a small portion of your data when tuning to make each iteration go faster.

To begin the tuning process create a citus cluster and load data in it. From the coordinator node, run the `EXPLAIN` command on representative queries to inspect performance. citus extends the `EXPLAIN` command to provide information about distributed query execution. The `EXPLAIN` output shows how each worker processes the query and also a little about how the coordinator node combines their results.

Here is an example of explaining the plan for a particular example query. We use the `VERBOSE` flag to see the actual queries, which were sent to the worker nodes.

```
EXPLAIN VERBOSE
 SELECT date_trunc('minute', created_at) AS minute,
        sum((payload->>'distinct_size')::int) AS num_commits
   FROM github_events
  WHERE event_type = 'PushEvent'
  GROUP BY minute
  ORDER BY minute;
```

```
Sort  (cost=0.00..0.00 rows=0 width=0)
  Sort Key: remote_scan.minute
  ->  HashAggregate  (cost=0.00..0.00 rows=0 width=0)
    Group Key: remote_scan.minute
    ->  Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
      Task Count: 32
      Tasks Shown: One of 32
      ->  Task
        Query: SELECT date_trunc('minute'::text, created_at) AS minute, sum(((payload
 OPERATOR(pg_catalog.->>) 'distinct_size'::text))::integer) AS num_commits FROM
 github_events_102042 github_events WHERE (event_type OPERATOR(pg_catalog.=)
 'PushEvent'::text) GROUP BY (date_trunc('minute'::text, created_at))
        Node: host=localhost port=5433 dbname=postgres
        ->  HashAggregate  (cost=93.42..98.36 rows=395 width=16)
          Group Key: date_trunc('minute'::text, created_at)
          ->  Seq Scan on github_events_102042 github_events  (cost=0.00..88.20
 rows=418 width=503)
            Filter: (event_type = 'PushEvent'::text)
(13 rows)
```

This tells you several things. To begin with there are 32 shards, and the planner chose the citus adaptive executor to execute this query:

```
->  Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
  Task Count: 32
```

Next it picks one of the workers and shows you more about how the query behaves there. It indicates the host, port, database, and the query that was sent to the worker so you can connect to the worker directly and try the query if desired:

```
Tasks Shown: One of 32
->  Task
  Query: SELECT date_trunc('minute'::text, created_at) AS minute, sum(((payload
 OPERATOR(pg_catalog.->>) 'distinct_size'::text))::integer) AS num_commits FROM
 github_events_102042 github_events WHERE (event_type OPERATOR(pg_catalog.=)
 'PushEvent'::text) GROUP BY (date_trunc('minute'::text, created_at))
  Node: host=localhost port=5433 dbname=postgres
```

Distributed `EXPLAIN` next shows the results of running a normal Postgres Pro `EXPLAIN` on that worker for the fragment query:

```
->  HashAggregate  (cost=93.42..98.36 rows=395 width=16)
  Group Key: date_trunc('minute'::text, created_at)
  ->  Seq Scan on github_events_102042 github_events  (cost=0.00..88.20 rows=418
 width=503)
    Filter: (event_type = 'PushEvent'::text)
```

You can now connect to the worker at `localhost`, port `5433` and tune query performance for the shard `github_events_102042` using standard Postgres Pro techniques. As you make changes run `EXPLAIN` again from the coordinator or right on the worker.

The first set of such optimizations relates to configuration settings. Postgres Pro by default comes with conservative resource settings; and among these settings shared_buffers and work_mem are probably the most important ones in optimizing read performance. We discuss these parameters in brief below. Apart from them, several other configuration settings impact query performance. These settings are covered in more detail in the Server Configuration chapter.

The `shared_buffers` configuration parameter defines the amount of memory allocated to the database for caching data and defaults to `128`MB. If you have a worker node with 1GB or more RAM, a reasonable starting value for `shared_buffers` is 1/4 of the memory in your system. There are some workloads where even larger settings for `shared_buffers` are effective, but given the way Postgres Pro also relies on the operating system cache, it is unlikely you will find using more than 25% of RAM to work better than a smaller amount.

If you do a lot of complex sorts, then increasing `work_mem` allows Postgres Pro to do larger in-memory sorts, which will be faster than disk-based equivalents. If you see lot of disk activity on your worker node inspite of having a decent amount of memory, then increasing `work_mem` to a higher value can be useful. This will help Postgres Pro in choosing more efficient query plans and allow for greater amount of operations to occur in memory.

Other than the above configuration settings, the Postgres Pro query planner relies on statistical information about the contents of tables to generate good plans. These statistics are gathered when `ANALYZE` is run, which is enabled by default. You can learn more about the Postgres Pro planner and the `ANALYZE` command in greater detail in the relevant section.

Lastly, you can create indexes on your tables to enhance database performance. Indexes allow the database to find and retrieve specific rows much faster than it could do without an index. To choose which indexes give the best performance, you can run the query with the `EXPLAIN` command to view query plans and optimize the slower parts of the query. After an index is created, the system has to keep it synchronized with the table which adds overhead to data manipulation operations. Therefore, indexes that are seldom or never used in queries should be removed.

For write performance, you can use general Postgres Pro configuration tuning to increase `INSERT` rates. We commonly recommend increasing checkpoint_timeout and max_wal_size settings. Also, depending on the reliability requirements of your application, you can choose to change fsync or synchronous_commit values.

Once you have tuned a worker to your satisfaction you will have to manually apply those changes to the other workers as well. To verify that they are all behaving properly, set this configuration variable on the coordinator:

```
SET citus.explain_all_tasks = 1;
```

This will cause `EXPLAIN` to show the query plan for all tasks, not just one.

```
EXPLAIN
 SELECT date_trunc('minute', created_at) AS minute,
        sum((payload->>'distinct_size')::int) AS num_commits
   FROM github_events
  WHERE event_type = 'PushEvent'
  GROUP BY minute
  ORDER BY minute;
```

```
Sort  (cost=0.00..0.00 rows=0 width=0)
  Sort Key: remote_scan.minute
  ->  HashAggregate  (cost=0.00..0.00 rows=0 width=0)
    Group Key: remote_scan.minute
    ->  Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
      Task Count: 32
      Tasks Shown: All
      ->  Task
```

```
        Node: host=localhost port=5433 dbname=postgres
        ->  HashAggregate  (cost=93.42..98.36 rows=395 width=16)
          Group Key: date_trunc('minute'::text, created_at)
          ->  Seq Scan on github_events_102042 github_events  (cost=0.00..88.20
rows=418 width=503)
            Filter: (event_type = 'PushEvent'::text)
      ->  Task
        Node: host=localhost port=5434 dbname=postgres
        ->  HashAggregate  (cost=103.21..108.57 rows=429 width=16)
          Group Key: date_trunc('minute'::text, created_at)
          ->  Seq Scan on github_events_102043 github_events  (cost=0.00..97.47
rows=459 width=492)
            Filter: (event_type = 'PushEvent'::text)
      --
      -- ... repeats for all 32 tasks
      --     alternating between workers one and two
      --     (running in this case locally on ports 5433, 5434)
      --

(199 rows)
```

Differences in worker execution can be caused by tuning configuration differences, uneven data distribution across shards, or hardware differences between the machines. To get more information about the time it takes the query to run on each shard you can use `EXPLAIN ANALYZE`.

> **Note**
>
> Note that when citus.explain_all_tasks is enabled, `EXPLAIN` plans are retrieved sequentially, which may take a long time for `EXPLAIN ANALYZE`.

citus, by default, sorts tasks by execution time in descending order. If citus.explain_all_tasks is disabled, then citus shows the single longest-running task. Please note that this functionality can be used only with `EXPLAIN ANALYZE`, since regular `EXPLAIN` does not execute the queries, and therefore does not know any execution times. To change the sort order, you can use the citus.explain_analyze_sort_method configuration parameter.

J.5.9.1.3. Scaling Out Performance

As mentioned, once you have achieved the desired performance for a single shard you can set similar configuration parameters on all your workers. As citus runs all the fragment queries in parallel across the worker nodes, users can scale out the performance of their queries to be the cumulative of the computing power of all of the CPU cores in the cluster assuming that the data fits in memory.

Users should try to fit as much of their working set in memory as possible to get best performance with citus. If fitting the entire working set in memory is not feasible, we recommend using SSDs over HDDs as a best practice. This is because HDDs are able to show decent performance when you have sequential reads over contiguous blocks of data, but have significantly lower random read / write performance. In cases where you have a high number of concurrent queries doing random reads and writes, using SSDs can improve query performance by several times as compared to HDDs. Also, if your queries are highly compute-intensive, it might be beneficial to choose machines with more powerful CPUs.

To measure the disk space usage of your database objects, you can log into the worker nodes and use Postgres Pro administration functions for individual shards. The `pg_total_relation_size` function can be used to get the total disk space used by a table. You can also use other functions mentioned in the Postgres Pro documentation to get more specific size information. On the basis of these statistics for a shard and the shard count, users can compute the hardware requirements for their cluster.

Another factor that affects performance is the number of shards per worker node. citus partitions an incoming query into its fragment queries which run on individual worker shards. Hence, the degree of

parallelism for each query is governed by the number of shards the query hits. To ensure maximum parallelism, you should create enough shards on each node such that there is at least one shard per CPU core. Another consideration to keep in mind is that citus will prune away unrelated shards if the query has filters on the distribution column. So, creating more shards than the number of cores might also be beneficial so that you can achieve greater parallelism even after shard pruning.

J.5.9.1.4. Distributed Query Performance Tuning

Once you have distributed your data across the cluster, with each worker optimized for best performance, you should be able to see high performance gains on your queries. After this, the final step is to tune a few distributed performance tuning parameters.

Before we discuss the specific configuration parameters, we recommend that you measure query times on your distributed cluster and compare them with the single shard performance. This can be done by enabling, timing, and running the query on the coordinator node and running one of the fragment queries on the worker nodes. This helps in determining the amount of time spent on the worker nodes and the amount of time spent in fetching the data to the coordinator node. Then, you can figure out what the bottleneck is and optimize the database accordingly.

In this section, we discuss the parameters that help optimize the distributed query planner and executor. There are several relevant parameters and we discuss them in two sections about general performance tuning and advanced performance tuning. The first section is sufficient for most use cases and covers all the common configs. The second covers parameters that may provide performance gains in specific use cases.

J.5.9.1.4.1. General Performance Tuning

For higher `INSERT` performance, the factor that impacts insert rates the most is the level of concurrency. You should try to run several concurrent `INSERT` statements in parallel. This way you can achieve very high insert rates if you have a powerful coordinator node and are able to use all the CPU cores on that node together.

Subquery/CTE Network Overhead

In the best case citus can execute queries containing subqueries and CTEs in a single step. This is usually because both the main query and subquery filter by distribution column of tables in the same way and can be pushed down to worker nodes together. However, citus is sometimes forced to execute subqueries *before* executing the main query, copying the intermediate subquery results to other worker nodes for use by the main query. This technique is called subquery/CTE push-pull execution.

It is important to be aware when subqueries are executed in a separate step and avoid sending too much data between worker nodes. The network overhead will hurt performance. The `EXPLAIN` command allows you to discover how queries will be executed, including whether multiple steps are required. For a detailed example, see the Subquery/CTE Push-Pull Execution section.

Also you can defensively set a safeguard against large intermediate results. Adjust the citus.max_intermediate_result_size limit in a new connection to the coordinator node. By default the max intermediate result size is `1` GB, which is large enough to allow some inefficient queries. Try turning it down and running your queries:

```
-- Set a restrictive limit for intermediate results
SET citus.max_intermediate_result_size = '512kB';

-- Attempt to run queries
-- SELECT …
```

If the query has subqueries or CTEs that exceed this limit, the query will be canceled and you will see an error message:

```
ERROR:  the intermediate result size exceeds citus.max_intermediate_result_size
 (currently 512 kB)
```

```
DETAIL:  Citus restricts the size of intermediate results of complex subqueries and
 CTEs to avoid accidentally pulling large result sets into once place.
HINT:  To run the current query, set citus.max_intermediate_result_size to a higher
 value or -1 to disable.
```

The size of intermediate results and their destination is available in `EXPLAIN ANALYZE` output:

```
EXPLAIN ANALYZE
WITH deleted_rows AS (
  DELETE FROM page_views WHERE tenant_id IN (3, 4) RETURNING *
), viewed_last_week AS (
  SELECT * FROM deleted_rows WHERE view_time > current_timestamp - interval '7 days'
)
SELECT count(*) FROM viewed_last_week;
```

```
Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0) (actual
 time=570.076..570.077 rows=1 loops=1)
  ->  Distributed Subplan 31_1
        Subplan Duration: 6978.07 ms

 loops=1)
                                Recheck Cond: (tenant_id = ANY ('{3,4}'::integer[]))
                                ->  Bitmap Index Scan on view_tenant_idx_102016
 (cost=0.00..5712.20 rows=324712 width=0) (actual time=19.193..19.193 rows=325733
 loops=1)
                                      Index Cond: (tenant_id = ANY
 ('{3,4}'::integer[]))
                        Planning Time: 0.050 ms
                        Execution Time: 363.426 ms
        Planning Time: 0.000 ms
        Execution Time: 364.241 ms
 Task Count: 1
 Tuple data received from nodes: 6 bytes
 Tasks Shown: All
 ->  Task
       Tuple data received from node: 6 bytes
       Node: host=localhost port=5432 dbname=postgres
       ->  Aggregate  (cost=33741.78..33741.79 rows=1 width=8) (actual
 time=565.008..565.008 rows=1 loops=1)
             ->  Function Scan on read_intermediate_result intermediate_result
 (cost=0.00..29941.56 rows=1520087 width=0) (actual time=326.645..539.158 rows=651466
 loops=1)
                   Filter: (view_time > (CURRENT_TIMESTAMP - '7 days'::interval))
           Planning Time: 0.047 ms
           Execution Time: 569.026 ms
Planning Time: 1.522 ms
```

```
Execution Time: 7549.308 ms
```

In the above `EXPLAIN ANALYZE` output, you can see the following information about the intermediate results:

```
Intermediate Data Size: 26 MB
Result destination: Write locally
```

It tells us how large the intermediate results were and where the intermediate results were written to. In this case, they were written to the node coordinating the query execution, as specified by `Write locally`. For some other queries it can also be of the following format:

```
Intermediate Data Size: 26 MB
Result destination: Send to 2 nodes
```

Which means the intermediate result was pushed to 2 worker nodes and it involved more network traffic.

When using CTEs, or joins between CTEs and distributed tables, you can avoid push-pull execution by following these rules:

- Tables should be co-located.
- The CTE queries should not require any merge steps (e.g., `LIMIT` or `GROUP BY` on a non-distribution key).
- Tables and CTEs should be joined on distribution keys.

Also Postgres Pro allows citus to take advantage of *CTE inlining* to push CTEs down to workers in more circumstances. The inlining behavior can be controlled with the `MATERIALIZED` keyword. To learn more, see the `WITH` Queries (Common Table Expressions) section.

J.5.9.1.4.2. Advanced Performance Tuning

In this section, we discuss advanced performance tuning parameters. These parameters are applicable to specific use cases and may not be required for all deployments.

Connection Management

When executing multi-shard queries, citus must balance the gains from parallelism with the overhead from database connections. The Query Execution section explains the steps of turning queries into worker tasks and obtaining database connections to the workers.

- Set the citus.max_adaptive_executor_pool_size configuration parameter to a low value like `1` or `2` for transactional workloads with short queries (e.g. < 20ms of latency). For analytical workloads where parallelism is critical, leave this setting at its default value of `16`.
- Set the citus.executor_slow_start_interval configuration parameter to a high value like `100` ms for transactional workloads comprised of short queries that are bound on network latency rather than parallelism. For analytical workloads, leave this setting at its default value of `10` ms.
- The default value of `1` for the citus.max_cached_conns_per_worker configuration parameter is reasonable. A larger value such as `2` might be helpful for clusters that use a small number of concurrent sessions, but it is not wise to go much further (e.g. `16` would be too high). If set too high, sessions will hold idle connections and use worker resources unnecessarily.
- Set the citus.max_shared_pool_size configuration parameter to match the max_connections setting of your *worker* nodes. This setting is mainly a fail-safe.

Task Assignment Policy

The citus query planner assigns tasks to the worker nodes based on shard locations. The algorithm used while making these assignments can be chosen by setting the citus.task_assignment_policy configuration parameter. Users can alter this configuration parameter to choose the policy, which works best for their use case.

The `greedy` policy aims to distribute tasks evenly across the workers. This policy is the default and works well in most of the cases. The `round-robin` policy assigns tasks to workers in a round-robin fashion alternating between different replicas. This enables much better cluster utilization when the shard count

for a table is low compared to the number of workers. The third policy is the `first-replica` policy that assigns tasks on the basis of the insertion order of placements (replicas) for the shards. With this policy, users can be sure of which shards will be accessed on each machine. This helps in providing stronger memory residency guarantees by allowing you to keep your working set in memory and use it for querying.

Binary protocol

In some cases, a large part of query time is spent in sending query results from workers to the coordinator. This mostly happens when queries request many rows (such as `SELECT * FROM table`), or when result columns use big types (like `hll` or `tdigest` from the hll and tdigest extensions).

In those cases it can be beneficial to set citus.enable_binary_protocol to `true`, which will change the encoding of the results to binary, rather than using text encoding. Binary encoding significantly reduces bandwidth for types that have a compact binary representation, such as `hll`, `tdigest`, `timestamp` and `double precision`. The default value for this configuration parameter is already `true`. So explicitly enabling it has no effect.

J.5.9.1.5. Scaling Out Data Ingestion

citus lets you scale out data ingestion to very high rates, but there are several trade-offs to consider in terms of application integration, throughput, and latency. In this section, we discuss different approaches to data ingestion, and provide guidelines for expected throughput and latency numbers.

J.5.9.1.5.1. Real-Time Insert and Updates

On the citus coordinator, you can perform `INSERT`, `INSERT .. ON CONFLICT`, `UPDATE`, and `DELETE` commands directly on distributed tables. When you issue one of these commands, the changes are immediately visible to the user.

When you run the `INSERT` (or another ingest command), citus first finds the right shard placements based on the value in the distribution column. citus then connects to the worker nodes storing the shard placements, and performs an `INSERT` on each of them. From the perspective of the user, the `INSERT` takes several milliseconds to process because of the network latency to worker nodes. The citus coordinator node, however, can process concurrent `INSERT`s to reach high throughputs.

J.5.9.1.5.2. Staging Data Temporarily

When loading data for temporary staging, consider using an unlogged table. These are tables which are not backed by the Postgres Pro write-ahead log. This makes them faster for inserting rows but not suitable for long term data storage. You can use an unlogged table as a place to load incoming data, prior to manipulating the data and moving it to permanent tables.

```
-- Example unlogged table
CREATE UNLOGGED TABLE unlogged_table (
  key text,
  value text
);

-- Its shards will be unlogged as well when
-- the table is distributed
SELECT create_distributed_table('unlogged_table', 'key');

-- Ready to load data
```

J.5.9.1.5.3. Bulk Copy (250K - 2M/s)

Distributed tables support the `COPY` from the citus coordinator for bulk ingestion, which can achieve much higher ingestion rates than `INSERT` statements.

`COPY` can be used to load data directly from an application using `COPY .. FROM STDIN`, from a file on the server, or program executed on the server.

```
COPY pgbench_history FROM STDIN WITH (FORMAT CSV);
```

In psql, the `\copy` command can be used to load data from the local machine. The `\COPY` command actually sends a `COPY .. FROM STDIN` command to the server before sending the local data, as would an application that loads data directly.

```
psql -c "\COPY pgbench_history FROM 'pgbench_history-2016-03-04.csv' (FORMAT CSV)"
```

A powerful feature of `COPY` for distributed tables is that it asynchronously copies data to the workers over many parallel connections, one for each shard placement. This means that data can be ingested using multiple workers and multiple cores in parallel. Especially when there are expensive indexes such as a GIN, this can lead to major performance boosts over ingesting into a regular Postgres Pro table.

From a throughput standpoint, you can expect data ingest ratios of 250K - 2M rows per second when using `COPY`.

Note

Make sure your benchmarking setup is well configured so you can observe optimal `COPY` performance. Follow these tips:

- We recommend a large batch size (~ 50000-100000). You can benchmark with multiple files (1, 10, 1000, 10000, etc), each of that batch size.
- Use parallel ingestion. Increase the number of threads/ingestors to 2, 4, 8, 16 and run benchmarks.
- Use a compute-optimized coordinator. For the workers choose memory-optimized boxes with a decent number of vCPUs.
- Go with a relatively small shard count, 32 should suffice, but you could benchmark with 64, too.
- Ingest data for a suitable amount of time (say 2, 4, 8, 24 hrs). Longer tests are more representative of a production setup.

J.5.9.2. Useful Diagnostic Queries

J.5.9.2.1. Finding Which Shard Contains Data For a Specific Tenant

The rows of a distributed table are grouped into shards, and each shard is placed on a worker node in the citus cluster. In the multi-tenant citus use case we can determine which worker node contains the rows for a specific tenant by putting together two pieces of information: the shard_id associated with the `tenant_id`, and the shard placements on workers. The two can be retrieved together in a single query. Suppose our multi-tenant application's tenants are stores, and we want to find which worker node holds the data for gap.com (`id=4`, suppose).

To find the worker node holding the data for store `id=4`, ask for the placement of rows whose distribution column has value 4:

```
SELECT shardid, shardstate, shardlength, nodename, nodeport, placementid
  FROM pg_dist_placement AS placement,
       pg_dist_node AS node
 WHERE placement.groupid = node.groupid
   AND node.noderole = 'primary'
   AND shardid = (
     SELECT get_shard_id_for_distribution_column('stores', 4)
   );
```

The output contains the host and port of the worker database.

```
┌─────────┬────────────┬─────────────┬──────────┬──────────┬─────────────┐
│ shardid │ shardstate │ shardlength │ nodename │ nodeport │ placementid │
```

```
┌──────────┬──────────────┬──────────────┬─────────────┬─────────────┬──────────────┐
│  102009  │            1 │            0 │ localhost   │        5433 │            2 │
└──────────┴──────────────┴──────────────┴─────────────┴─────────────┴──────────────┘
```

J.5.9.2.2. Finding Which Node Hosts a Distributed Schema

Distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas are converted to co-located distributed tables without a shard key. You can find where a distributed schema resides by joining the citus_shards view with the citus_schemas view:

```
SELECT schema_name, nodename, nodeport
  FROM citus_shards
  JOIN citus_schemas cs
    ON cs.colocation_id = citus_shards.colocation_id
 GROUP BY 1,2,3;
```

```
schema_name | nodename  | nodeport
------------+-----------+----------
a           | localhost |     9701
b           | localhost |     9702
with_data   | localhost |     9702
```

You can also query `citus_shards` directly filtering down to schema table type to have a detailed listing for all tables.

```
SELECT * FROM citus_shards WHERE citus_table_type = 'schema';
```

```
  table_name   | shardid |      shard_name       | citus_table_type | colocation_id
 | nodename  | nodeport | shard_size | schema_name | colocation_id | schema_size |
 schema_owner
----------------+---------+-----------------------+------------------+---------------
+-----------+----------+------------+-------------+---------------+-------------
+--------------
a.cities       |  102080 | a.cities_102080       | schema           |             4 |
 localhost |     9701 |       8192 | a           |             4 | 128 kB      | citus
a.map_tags     |  102145 | a.map_tags_102145     | schema           |             4 |
 localhost |     9701 |      32768 | a           |             4 | 128 kB      | citus
a.measurement  |  102047 | a.measurement_102047  | schema           |             4 |
 localhost |     9701 |          0 | a           |             4 | 128 kB      | citus
a.my_table     |  102179 | a.my_table_102179     | schema           |             4 |
 localhost |     9701 |      16384 | a           |             4 | 128 kB      | citus

 localhost |     9701 |      32768 | a           |             4 | 128 kB      | citus
b.test         |  102009 | b.test_102009         | schema           |             5 |
 localhost |     9702 |       8192 | b           |             5 | 32 kB       | citus
b.test_col     |  102012 | b.test_col_102012     | schema           |             5 |
 localhost |     9702 |      24576 | b           |             5 | 32 kB       | citus
with_data.test |  102180 | with_data.test_102180 | schema           |            11 |
 localhost |     9702 |     647168 | with_data   |            11 | 632 kB      | citus
```

J.5.9.2.3. Finding the Distribution Column For a Table

Each distributed table in citus has a “distribution column”. For more information about what this is and how it works, see the Choosing Distribution Column section. There are many situations where it is important to know which column it is. Some operations require joining or filtering on the distribution column, and you may encounter error messages with hints like `add a filter to the distribution column`.

The `pg_dist_*` tables on the coordinator node contain diverse metadata about the distributed database. In particular the pg_dist_partition table holds information about the distribution column (formerly called *partition* column) for each table. You can use a convenient utility function to look up the distribution column name from the low-level details in the metadata. Here is an example and its output:

```
-- Create example table

CREATE TABLE products (
  store_id bigint,
  product_id bigint,
  name text,
  price money,

  CONSTRAINT products_pkey PRIMARY KEY (store_id, product_id)
);

-- Pick store_id as distribution column

SELECT create_distributed_table('products', 'store_id');

-- Get distribution column name for products table

SELECT column_to_column_name(logicalrelid, partkey) AS dist_col_name
  FROM pg_dist_partition
 WHERE logicalrelid='products'::regclass;
```

Example output:

```
┌──────────────┐
│ dist_col_name │
├──────────────┤
│ store_id     │
└──────────────┘
```

J.5.9.2.4. Detecting Locks

This query will run across all worker nodes and identify locks, how long they have been open, and the offending queries:

```
SELECT * FROM citus_lock_waits;
```

For more information, see the Distributed Query Activity section.

J.5.9.2.5. Querying the Size of Your Shards

This query will provide you with the size of every shard of a given distributed table, designated here with the placeholder *`my_table`*:

```
SELECT shardid, table_name, shard_size
FROM citus_shards
WHERE table_name = 'my_table';
```

Example output:

```
.
 shardid | table_name | shard_size
---------+------------+------------
  102170 | my_table   |   90177536
  102171 | my_table   |   90177536
  102172 | my_table   |   91226112
  102173 | my_table   |   90177536
```

This query uses the citus_shards view.

J.5.9.2.6. Querying the Size of All Distributed Tables

This query gets a list of the sizes for each distributed table plus the size of their indices.

```
SELECT table_name, table_size
  FROM citus_tables;
```

Example output:

```
┌─────────────────┬────────────┐
│   table_name    │ table_size │
├─────────────────┼────────────┤
│ github_users    │ 39 MB      │
│ github_events   │ 98 MB      │
└─────────────────┴────────────┘
```

There are other ways to measure distributed table size as well. To learn more, see the Determining Table and Relation Size section.

J.5.9.2.7. Identifying Unused Indices

This query will run across all worker nodes and identify any unused indexes for a given distributed table, designated here with the placeholder *my_distributed_table*:

```
SELECT *
FROM run_command_on_shards('my_distributed_table', $cmd$
  SELECT array_agg(a) as infos
  FROM (
    SELECT (
      schemaname || '.' || relname || '##' || indexrelname || '##'
                 || pg_size_pretty(pg_relation_size(i.indexrelid))::text
                 || '##' || idx_scan::text
    ) AS a
    FROM  pg_stat_user_indexes ui
    JOIN  pg_index i
    ON    ui.indexrelid = i.indexrelid
    WHERE NOT indisunique
    AND   idx_scan < 50
    AND   pg_relation_size(relid) > 5 * 8192
    AND   (schemaname || '.' || relname)::regclass = '%s'::regclass
    ORDER BY
      pg_relation_size(i.indexrelid) / NULLIF(idx_scan, 0) DESC nulls first,
      pg_relation_size(i.indexrelid) DESC
  ) sub
$cmd$);
```

Example output:

```
┌─────────┬─────────┬──────────────────────────────────────────────────────────────────────────────────────────────────────────────────
│ shardid │ success │                                 result
                  │
├─────────┼─────────┼──────────────────────────────────────────────────────────────────────────────────────────────────────────────────
│  102008 │ t       │
                  │
│  102009 │ t       │ {"public.my_distributed_table_102009##stupid_index_102009##28
 MB##0"}           │
│  102010 │ t       │
                  │
│  102011 │ t       │
                  │
└─────────┴─────────┴──────────────────────────────────────────────────────────────────────────────────────────────────────────────────
```

J.5.9.2.8. Monitoring Client Connection Count

This query will give you the connection count by each type that are open on the coordinator:

```
SELECT state, count(*)
FROM pg_stat_activity
GROUP BY state;
```

Example output:

```
┌──────────┬──────────┐
│ state    │ count    │
├──────────┼──────────┤
│ active   │        3 │
│ ∅        │        1 │
└──────────┴──────────┘
```

J.5.9.2.9. Viewing System Queries

J.5.9.2.9.1. Active Queries

The citus_stat_activity shows which queries are currently executing. You can filter to find the actively executing ones, along with the process ID of their backend:

```
SELECT global_pid, query, state
  FROM citus_stat_activity
 WHERE state != 'idle';
```

J.5.9.2.9.2. Why Are Queries Waiting

We can also query to see the most common reasons that non-idle queries that are waiting. For an explanation of the reasons, see the Wait Event Types table.

```
SELECT wait_event || ':' || wait_event_type AS type, count(*) AS number_of_occurences
  FROM pg_stat_activity
 WHERE state != 'idle'
GROUP BY wait_event, wait_event_type
ORDER BY number_of_occurences DESC;
```

Example output when executing the pg_sleep function in a separate query concurrently:

```
┌──────────────────┬──────────────────────┐
│       type       │ number_of_occurences │
├──────────────────┼──────────────────────┤
│ ∅                │                    1 │
│ PgSleep:Timeout  │                    1 │
└──────────────────┴──────────────────────┘
```

J.5.9.2.10. Index Hit Rate

This query will provide you with your index hit rate across all nodes. Index hit rate is useful in determining how often indices are used when querying:

```
-- On coordinator
SELECT 100 * (sum(idx_blks_hit) - sum(idx_blks_read)) / sum(idx_blks_hit) AS
 index_hit_rate
  FROM pg_statio_user_indexes;

-- On workers
SELECT nodename, result as index_hit_rate
FROM run_command_on_workers($cmd$
  SELECT 100 * (sum(idx_blks_hit) - sum(idx_blks_read)) / sum(idx_blks_hit) AS
 index_hit_rate
```

```
    FROM pg_statio_user_indexes;
$cmd$);
```

Example output:

```
┌─────────────┬────────────────────┐
│ nodename    │ index_hit_rate     │
├─────────────┼────────────────────┤
│ 10.0.0.16   │ 96.0               │
│ 10.0.0.20   │ 98.0               │
└─────────────┴────────────────────┘
```

J.5.9.2.11. Cache Hit Rate

Most applications typically access a small fraction of their total data at once. Postgres Pro keeps frequently accessed data in memory to avoid slow reads from disk. You can see statistics about it in the pg_statio_user_tables view.

An important measurement is what percentage of data comes from the memory cache vs the disk in your workload:

```
-- On coordinator
SELECT
  sum(heap_blks_read) AS heap_read,
  sum(heap_blks_hit)  AS heap_hit,
  100 * sum(heap_blks_hit) / (sum(heap_blks_hit) + sum(heap_blks_read)) AS
 cache_hit_rate
FROM
  pg_statio_user_tables;

-- On workers
SELECT nodename, result as cache_hit_rate
FROM run_command_on_workers($cmd$
  SELECT
    100 * sum(heap_blks_hit) / (sum(heap_blks_hit) + sum(heap_blks_read)) AS
 cache_hit_rate
  FROM
    pg_statio_user_tables;
$cmd$);
```

Example output:

```
┌────────────┬────────────┬──────────────────────┐
│ heap_read  │ heap_hit   │   cache_hit_rate     │
├────────────┼────────────┼──────────────────────┤
│          1 │        132 │ 99.2481203007518796  │
└────────────┴────────────┴──────────────────────┘
```

If you find yourself with a ratio significantly lower than 99%, then you likely want to consider increasing the cache available to your database.

J.5.9.3. Common Error Messages

J.5.9.3.1. `could not connect to server: Connection refused`

Caused when the coordinator node is unable to connect to a worker.

```
SELECT 1 FROM companies WHERE id = 2928;

ERROR:  connection to the remote node localhost:5432 failed with the following error:
 could not connect to server: Connection refused
        Is the server running on host "localhost" (127.0.0.1) and accepting
```

```
        TCP/IP connections on port 5432?
```

J.5.9.3.1.1. Resolution

To fix, check that the worker is accepting connections, and that DNS is correctly resolving.

J.5.9.3.2. `canceling the transaction since it was involved in a distributed deadlock`

Deadlocks can happen not only in a single-node database, but in a distributed database, caused by queries executing across multiple nodes. citus has the intelligence to recognize distributed deadlocks and defuse them by aborting one of the queries involved.

We can see this in action by distributing rows across worker nodes and then running two concurrent transactions with conflicting updates:

```
CREATE TABLE lockme (id int, x int);
SELECT create_distributed_table('lockme', 'id');

-- id=1 goes to one worker, and id=2 another
INSERT INTO lockme VALUES (1,1), (2,2);

--------------- TX 1 ----------------  --------------- TX 2 ----------------
BEGIN;
                                       BEGIN;
UPDATE lockme SET x = 3 WHERE id = 1;
                                       UPDATE lockme SET x = 4 WHERE id = 2;
UPDATE lockme SET x = 3 WHERE id = 2;
                                       UPDATE lockme SET x = 4 WHERE id = 1;
ERROR:  canceling the transaction since it was involved in a distributed deadlock
```

J.5.9.3.2.1. Resolution

Detecting deadlocks and stopping them is part of normal distributed transaction handling. It allows an application to retry queries or take another course of action.

J.5.9.3.3. `could not connect to server: Cannot assign requested address`

```
WARNING:  connection error: localhost:9703
DETAIL:  could not connect to server: Cannot assign requested address
```

This occurs when there are no more sockets available by which the coordinator can respond to worker requests.

J.5.9.3.3.1. Resolution

Configure the operating system to re-use TCP sockets. Execute this on the shell in the coordinator node:

```
sysctl -w net.ipv4.tcp_tw_reuse=1
```

This allows reusing sockets in `TIME_WAIT` state for new connections when it is safe from a protocol viewpoint. Default value is `0` (disabled).

J.5.9.3.4. `SSL error: certificate verify failed`

In citus, nodes are required talk to one another using SSL by default. If SSL is not enabled on a Postgres Pro server when citus is first installed, the install process will enable it, which includes creating and self-signing an SSL certificate.

However, if a root certificate authority file exists (typically in `~/.postgresql/root.crt`), then the certificate will be checked unsuccessfully against that Certificate Authority at connection time.

J.5.9.3.4.1. Resolution

Possible solutions are to sign the certificate, turn off SSL, or remove the root certificate. Also a node may have trouble connecting to itself without the help of the citus.local_hostname configuration parameter.

J.5.9.3.5. `could not connect to any active placements`

When all available worker connection slots are in use, further connections will fail.

```
WARNING:  connection error: hostname:5432
ERROR:  could not connect to any active placements
```

J.5.9.3.5.1. Resolution

This error happens most often when copying data into citus in parallel. The `COPY` command opens up one connection per shard. If you run M concurrent copies into a destination with N shards, that will result in M*N connections. To solve the error, reduce the shard count of target distributed tables, or run fewer `\copy` commands in parallel.

J.5.9.3.6. `remaining connection slots are reserved for non-replication superuser connections`

This occurs when Postgres Pro runs out of available connections to serve concurrent client requests.

J.5.9.3.6.1. Resolution

The max_connections configuration parameter adjusts the limit, with a typical default of 100 connections. Note that each connection consumes resources, so adjust sensibly. When increasing `max_connections` it is usually a good idea to increase memory limits too.

Using pgbouncer can also help by queueing connection requests, which exceed the connection limit.

J.5.9.3.7. `pgbouncer cannot connect to server`

In a self-hosted citus cluster, this error indicates that the coordinator node is not responding to pgbouncer.

J.5.9.3.7.1. Resolution

Try connecting directly to the server with psql to ensure it is running and accepting connections.

J.5.9.3.8. `creating unique indexes on non-partition columns is currently unsupported`

As a distributed system, citus can guarantee uniqueness only if a unique index or primary key constraint includes a table distribution column. That is because the shards are split so that each shard contains non-overlapping partition column values. The index on each worker node can locally enforce its part of the constraint.

Trying to make a unique index on a non-distribution column will generate an error:

```
ERROR:  creating unique indexes on non-partition columns is currently unsupported
```

Enforcing uniqueness on a non-distribution column would require citus to check every shard on every `INSERT` to validate, which defeats the goal of scalability.

J.5.9.3.8.1. Resolution

There are two ways to enforce uniqueness on a non-distribution column:

1. Create a composite unique index or primary key that includes the desired column (*C*), but also includes the distribution column (*D*). This is not quite as strong a condition as uniqueness on *C* alone, but will ensure that the values of *C* are unique for each value of *D*. For instance if distributing by `company_id` in a multi-tenant system, this approach would make *C* unique within each company.
2. Use a reference table rather than a hash-distributed table. This is only suitable for small tables, since the contents of the reference table will be duplicated on all nodes.

J.5.9.3.9. `function create_distributed_table does not exist`

```
SELECT create_distributed_table('foo', 'id');
/*
ERROR:  function create_distributed_table(unknown, unknown) does not exist
LINE 1: SELECT create_distributed_table('foo', 'id');
```

```
HINT:  No function matches the given name and argument types. You might need to add
 explicit type casts.
*/
```

J.5.9.3.9.1. Resolution

When basic utility functions are not available, check whether the citus extension is properly installed. Running `\dx` in psql will list installed extensions.

One way to end up without extensions is by creating a new database in a Postgres Pro server, which requires extensions to be re-installed. See the Creating a New Database section to learn how to do it right.

J.5.9.3.10. STABLE functions used in UPDATE queries cannot be called with column references

Each Postgres Pro function has a volatility classification, which indicates whether the function can update the database and whether the function's return value can vary over time given the same inputs. A `STABLE` function is guaranteed to return the same results given the same arguments for all rows within a single statement, while an `IMMUTABLE` function is guaranteed to return the same results given the same arguments forever.

Non-immutable functions can be inconvenient in distributed systems because they can introduce subtle changes when run at slightly different times across shards. Differences in database configuration across nodes can also interact harmfully with non-immutable functions.

One of the most common ways this can happen is using the `timestamp` in Postgres Pro, which unlike `timestamptz` does not keep a record of time zone. Interpreting a timestamp column makes reference to the database timezone, which can be changed between queries, hence functions operating on timestamps are not immutable.

citus forbids running distributed queries that filter results using stable functions on columns. For instance:

```
-- foo_timestamp is timestamp, not timestamptz
UPDATE foo SET ... WHERE foo_timestamp < now();

ERROR:  STABLE functions used in UPDATE queries cannot be called with column references
```

In this case the comparison operator `<` between `timestamp` and `timestamptz` is not immutable.

J.5.9.3.10.1. Resolution

Avoid stable functions on columns in a distributed `UPDATE` statement. In particular, whenever working with times use `timestamptz` rather than `timestamp`. Having a time zone in `timestamptz` makes calculations immutable.

J.5.10. Frequently Asked Questions

J.5.10.1. Can I create primary keys on distributed tables?

Currently citus imposes primary key constraint only if the distribution column is a part of the primary key. This assures that the constraint needs to be checked only on one shard to ensure uniqueness.

J.5.10.2. How do I add nodes to an existing citus cluster?

With citus, you can add nodes manually by calling the citus_add_node function with the hostname (or IP address) and port number of the new node.

After adding a node to an existing cluster, the new node will not contain any data (shards). citus will start assigning any newly created shards to this node. To rebalance existing shards from the older nodes to the new node, citus provides an open source shard rebalancer utility. You can find more information in the Rebalancing Shards Without Downtime section.

J.5.10.3. How does citus handle failure of a worker node?

citus uses Postgres Pro streaming replication to replicate the entire worker-node as-is. It replicates worker nodes by continuously streaming their WAL records to a standby. You can configure streaming replication on-premise yourself by consulting the Streaming Replication section.

J.5.10.4. How does citus handle failover of the coordinator node?

As the citus coordinator node is similar to a standard Postgres Pro server, regular Postgres Pro synchronous replication and failover can be used to provide higher availability of the coordinator node. To learn more about handling coordinator node failures, see the Coordinator Node Failures section.

J.5.10.5. Are there any Postgres Pro features not supported by citus?

Since citus provides distributed functionality by extending Postgres Pro, it uses the standard Postgres Pro SQL constructs. The vast majority of queries are supported, even when they combine data across the network from multiple database nodes. This includes transactional semantics across nodes. For an up-to-date list of SQL coverage, see the Limitations section.

What's more, citus has 100% SQL support for queries that access a single node in the database cluster. These queries are common, for instance, in multi-tenant applications where different nodes store different tenants. To learn more, see the When to Use citus section.

Remember that even with this extensive SQL coverage data modeling can have a significant impact on query performance. See the Query Processing section for details on how citus executes queries.

J.5.10.6. How do I choose the shard count when I hash-partition my data?

One of the choices when first distributing a table is its shard count. This setting can be set differently for each co-location group, and the optimal value depends on the use case. It is possible, but difficult, to change the count after cluster creation, so use these guidelines to choose the right size.

In the multi-tenant SaaS database use case we recommend choosing between 32 and 128 shards. For smaller workloads, say <100GB, you could start with 32 shards and for larger workloads you could choose 64 or 128. This means that you have the leeway to scale from 32 to 128 worker machines.

In the real-time analytics use case, shard count should be related to the total number of cores on the workers. To ensure maximum parallelism, you should create enough shards on each node such that there is at least one shard per CPU core. We typically recommend creating a high number of initial shards, e.g. 2x or 4x the number of current CPU cores. This allows for future scaling if you add more workers and CPU cores.

To choose a shard count for a table you wish to distribute, update the citus.shard_count configuration parameter. This affects subsequent calls to the create_distributed_table function. For example:

```
SET citus.shard_count = 64;
-- any tables distributed at this point will have
-- sixty-four shards
```

For more guidance on this topic, see the Choosing Cluster Size section.

J.5.10.7. How do I change the shard count for a hash-partitioned table?

citus has a function called alter_distributed_table that can change the shard count of a distributed table.

J.5.10.8. How does citus support `count(distinct)` queries?

citus can evaluate `count(distinct)` aggregates both in and across worker nodes. When aggregating on a table's distribution column, citus can push the counting down inside worker nodes and total the results. Otherwise it can pull distinct rows to the coordinator and calculate there. If transferring data to the coordinator is too expensive, fast approximate counts are also available. More details in The `count(distinct)` Aggregates section.

J.5.10.9. In which situations are uniqueness constraints supported on distributed tables?

citus is able to enforce a primary key or uniqueness constraint only when the constrained columns contain the distribution column. In particular this means that if a single column constitutes the primary key then it has to be the distribution column as well.

This restriction allows citus to localize a uniqueness check to a single shard and let Postgres Pro on the worker node do the check efficiently.

J.5.10.10. How do I create database roles, functions, extensions etc in a citus cluster?

Certain commands, when run on the coordinator node, do not get propagated to the workers:

- `CREATE ROLE/USER`
- `CREATE DATABASE`
- `ALTER … SET SCHEMA`
- `ALTER TABLE ALL IN TABLESPACE`
- `CREATE TABLE` (see the Table Types section)

For the other types of objects above, create them explicitly on all nodes. citus provides a function to execute queries across all workers:

```
SELECT run_command_on_workers($cmd$
  /* the command to run */
  CREATE ROLE ...
$cmd$);
```

Learn more in the Manual Query Propagation section. Also note that even after manually propagating `CREATE DATABASE`, citus must still be installed there. See the Creating a New Database section.

In the future citus will automatically propagate more kinds of objects. The advantage of automatic propagation is that citus will automatically create a copy on any newly added worker nodes (see the citus.pg_dist_object table to learn more).

J.5.10.11. What if a worker node's address changes?

If the hostname or IP address of a worker changes, you need to let the coordinator know using the citus_update_node function:

```
-- Update worker node metadata on the coordinator
-- (remember to replace 'old-address' and 'new-address'
--  with the actual values for your situation)

SELECT citus_update_node(nodeid, 'new-address', nodeport)
  FROM pg_dist_node
 WHERE nodename = 'old-address';
```

Until you execute this update, the coordinator will not be able to communicate with that worker for queries.

J.5.10.12. Which shard contains data for a particular tenant?

citus provides utility functions and metadata tables to determine the mapping of a distribution column value to a particular shard, and the shard placement on a worker node. See the Finding Which Shard Contains Data For a Specific Tenant section for more details.

J.5.10.13. I forgot the distribution column of a table, how do I find it?

The citus coordinator node metadata tables contain this information. See the Finding the Distribution Column For a Table section.

J.5.10.14. Can I distribute a table by multiple keys?

No, you must choose a single column per table as the distribution column. A common scenario where people want to distribute by two columns is for timeseries data. However, for this case we recommend using a hash distribution on a non-time column, and combining this with Postgres Pro partitioning on the time column, as described in the Timeseries Data section.

J.5.10.15. Why does `pg_relation_size` report zero bytes for a distributed table?

The data in distributed tables lives on the worker nodes (in shards), not on the coordinator. A true measure of distributed table size is obtained as a sum of shard sizes. citus provides helper functions to query this information. See the Determining Table and Relation Size section to learn more.

J.5.10.16. Why am I seeing an error about `citus.max_intermediate_result_size`?

citus has to use more than one step to run some queries having subqueries or CTEs. Using the subquery/CTE push-pull execution, it pushes subquery results to all worker nodes for use by the main query. If these results are too large, this might cause unacceptable network overhead, or even insufficient storage space on the coordinator node which accumulates and distributes the results.

citus has a configurable setting citus.max_intermediate_result_size to specify a subquery result size threshold at which the query will be canceled. If you run into the error, it looks like:

```
ERROR:  the intermediate result size exceeds citus.max_intermediate_result_size
 (currently 1 GB)
DETAIL:  Citus restricts the size of intermediate results of complex subqueries and
 CTEs to avoid accidentally pulling large result sets into once place.
HINT:  To run the current query, set citus.max_intermediate_result_size to a higher
 value or -1 to disable.
```

As the error message suggests, you can (cautiously) increase this limit by altering the variable:

```
SET citus.max_intermediate_result_size = '3GB';
```

J.5.10.17. Can I shard by schema on citus for multi-tenant applications?

Yes, schema-based sharding is available.

J.5.10.18. How does cstore_fdw work with citus?

The cstore_fdw extension is no longer needed on Postgres Pro 12 and above, because columnar storage is now implemented directly in citus. Unlike cstore_fdw, columnar tables of the citus support transactional semantics, replication, and pg_upgrade. citus query parallelization, seamless sharding, and high-availability benefits combine powerfully with the superior compression and I/O utilization of columnar storage for large dataset archival and reporting.

Appendix K. Configuring Postgres Pro for 1C Solutions

You can install and use Postgres Pro with 1C solutions in a client/server model.

Make sure that the Russian locale (such as `ru_RU.UTF-8` on Linux systems) is installed and that it is the active locale of the user who creates the database cluster. For example, for Debian systems do the following:

```
sudo dpkg-reconfigure locales # Choose locale ru_RU.UTF-8 to generate
export LANG="ru_RU.UTF-8"
/opt/pgpro/ent-16/bin/pg-setup initdb
```

For more details, see related sections of the documentation for your operating system and for 1C.

Also, for optimal performance and stability, modify the following settings in the `postgresql.conf` configuration file of Postgres Pro server:

1. Increase the maximum number of allowed concurrent connections to the database server, up to 1000 connections. 1C solutions can open a large number of connections, even if not all of them are used, so it is recommended to allow not less than 500 connections.

   ```
   max_connections = 1000
   ```

2. To ensure that temporary tables are handled correctly, modify the following parameters:

   - Increase the buffer size for temporary tables:

     ```
     temp_buffers = 32MB
     ```

   - Increase the number of allowed locks of tables or indexes per transaction to 256:

     ```
     max_locks_per_transaction = 256
     ```

     Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail, leaving multiple orphaned temporary tables.

3. Enable backslash escapes in all strings, and switch off the warning about using the backslash escape symbol:

   ```
   standard_conforming_strings = off
   escape_string_warning = off
   ```

4. Set the `effective_cache_size` parameter to at least half of RAM available on the system. Postgres Pro query optimizer performance depends on the amount of allocated RAM.

5. To use the logical replication mechanism of the `dbcopies_decoding` module, `wal_level` must be set to `logical`.

6. Optimize query planning using `plantuner` extension, as follows:

   - Add `plantuner` to the `shared_preload_libraries` variable:

     ```
     shared_preload_libraries = 'plantuner'
     ```

   - Tune Postgres Pro optimizer to improve planning for recently created empty tables:

     ```
     plantuner.fix_empty_table = 'on'
     ```

Appendix L. Migration Tools in Postgres Pro

Postgres Pro provides tools that can be useful when migrating from Oracle to Postgres Pro in addition to native support.

L.1. Working with Packages

Postgres Pro provides packages, which are similar to packages in Oracle, and can be useful when porting from PL/SQL to PL/pgSQL. This section explains differences between Postgres Pro's and Oracle's packages.

In Oracle, a package is a schema object that groups logically related types, global variables, and subprograms (procedures and functions). A package consists of a package specification and a package body (in general, the package body is optional). In the package specification, those items are declared that can be referenced from outside the package and used in applications: types, variables, constants, exceptions, cursors, and subprograms. The package body contains package subprogram implementation, private variable declarations, and the initialization section. The variables, types and subprograms declared in the package body cannot be used from outside the package.

The example below shows the package specification of the PL/SQL `counter` package in Oracle, which contains the global variable `n` and the function `inc`:

```
CREATE PACKAGE counter IS
    n int;

    FUNCTION inc RETURN int;
END;
```

The function `inc` and the global variable `k` (available only in the package body) are declared in the `counter` package body in Oracle.

```
CREATE PACKAGE BODY counter IS
    k int := 3; -- the variable is available only in the package body

    FUNCTION inc RETURN int IS
    BEGIN
        n := n + 1;
        RETURN n;
    END;

-- Package initialization
BEGIN
    n := 1;
    FOR i IN 1..10 LOOP
        n := n + n;
    END LOOP;
END;
```

Global package variables exist during the session lifetime. Note that the package body contains the initialization section — the code block executed once a session when any package element is accessed for the first time. In Oracle, package elements could be accessed using dot notation as follows: *package_name*.*package_element*.

```
SET SERVEROUTPUT ON

BEGIN
```

```
    dbms_output.put_line(counter.n);
    dbms_output.put_line(counter.inc());
END;
/

1024
1025
```

A package in Postgres Pro is essentially a schema that contains the initialization function and may contain only functions, procedures and composite types. The initialization function is a PL/pgSQL function named `__init__` that has no arguments and returns `void`. The initialization function must be defined before any other package function. By default, all the variables declared in the package initialization function, package functions and package procedures are public, so they can be called using dot notation from outside the package by other functions, procedures and anonymous blocks that import the package. The `#private` modifier defines functions and procedures as private, and the `#export` modifier defines which package variables are public. For example, the `bar` variable declared in the `__init__` function of the `foo` package can be referenced as `foo.bar`.

Package variables can be accessed only from PL/pgSQL code. To retrieve the value of the global variable in an SQL query (`SELECT`) or in a DML operation (`INSERT`, `UPDATE`, `DELETE`), add a getter function that returns the value to the caller. For package variables declared as constant, default definition syntax in PL/pgSQL is used. The package initialization function is invoked automatically when any of the following elements is accessed in the current session:

- Any function in this package with the `#package` modifier
- Code block (anonymous or a function) importing this package

The initialization function can be invoked manually to reset values of package variables. To do that, you can also use a built-in function `plpgsql_reset_packages()` but it resets all the packages in the current session (similar to `DBMS_SESSION.RESET_PACKAGES` in Oracle).

The above example of the Oracle's `counter` package after porting to Postgres Pro will look like this:

```
CREATE PACKAGE counter

    CREATE FUNCTION __init__() RETURNS void AS $$ -- package initialization
    #export n
    DECLARE
        n int := 1; -- n public variable, available both inside and outside the package
        k int := 3; -- k private variable, only available inside the package
    BEGIN
        FOR i IN 1..10 LOOP
            n := n + n;
        END LOOP;
    END;
    $$

    CREATE FUNCTION inc() RETURNS int AS $$
    BEGIN
        n := n + 1;
        RETURN n;
    END;
    $$
;
```

You can use this package in Postgres Pro as follows:

```
DO $$
#import counter
BEGIN
```

```
    RAISE NOTICE '%', counter.n;
    RAISE NOTICE '%', counter.inc();
END;
$$;

NOTICE:  1024
NOTICE:  1025
```

There are some points worth noting.

- Schemas cannot contain packages, as the package itself is a schema.
- The package name must be distinct from the name of any existing package or schema in the current database.
- A package may contain only composite types, global variables, procedures, and functions (for example, tables, views, sequences *cannot* be created in packages).
- All package variables are public if the `#export on` modifier is used or if there is no `#export` modifier at all. All the package functions and procedures are public unless the `#private` modifier is used. Public package variables are available from any code block importing the package.
- Package specification and package body are *not* defined separately.
- Package functions and code blocks importing them must be written in PL/pgSQL.
- All package elements must be accessed from outside the package using qualified names, i.e. using package name. From inside the package, functions can access them directly.
- Global package variables can be initialized when declared:

  ```
  DECLARE x int := 42;
  ```

  or later in the initialization function `__init__`. For the external code using the package, it doesn't matter.
- Types must be declared in the beginning of the package before the first subprogram.
- The `__init__` function must be the first subprogram defined in the package.

To support packages in Postgres Pro, the following enhancements were introduced:

- Function modifiers
- Built-in functions
- `CREATE [OR REPLACE] PACKAGE` and `DROP PACKAGE` SQL commands

L.1.1. Function and Variable Modifiers

Function and variable modifiers start with `#` and are placed between the name and the `DECLARE` statement (see example below).

L.1.1.1. `#package` Modifier

The modifier `#package` indicates that the function should be treated as a package function, which means the following:

- When the function is called, the package is initialized automatically if it hasn't been initialized in the current session.
- The function can access the variables of its package directly.

The `__init__` function must not contain the `#package` modifier. A function with the `#package` modifier can be created only in a schema that already contains the `__init__` function (that is, in a package). If you create a function within the `CREATE OR REPLACE PACKAGE`, the `#package` modifier may be omitted as it is added automatically in this command.

L.1.1.2. `#import` Modifier

The modifier `#import` indicates that the function is supposed to work with variables of an outside package (or a number of packages). This is called package import and means the following:

- When this function is accessed, the imported package is initialized automatically if it hasn't been initialized in the current session.
- The function can access the variables of the imported package using package name. To import the package, use the following syntax:

  ```
  #import packages_list
  ```

  Here *packages_list* is the list of imported package names. You can also import packages separately, for example:

  ```
  #import foo, bar
  ```

  would mean the same as:

  ```
  #import foo
  #import bar
  ```

All the packages imported in the `__init__` function are automatically imported for other functions of the package.

In the below example of using the `#import` modifier, the `showValues` procedure calls `p` of the `htp` package and `set_action` of the `dbms_application_info` package.

```
CREATE OR REPLACE PROCEDURE showValues(p_Str varchar) AS $$
#import htp, dbms_application_info
BEGIN
  CALL dbms_application_info.set_action('Show hello');

  CALL htp.p('<p>' || p_Str || '</p>');
END;
$$LANGUAGE plpgsql;
```

L.1.1.3. `#private` Modifier

The `#private` modifier indicates that the function is private, meaning that it is only available inside the package and cannot be referenced from outside it. Private functions are necessary for the internal processes of the package. They are only available in the package that specifies them.

L.1.1.4. `#export` Modifier

The modifier `#export` indicates that the package variable is public, meaning it can be referenced from outside the package. The `#export` modifier is used when initializing a package:

```
#export var_name_1, var_name_2, ... var_name_N
```

- If the package does not contain the `#export` modifier, all the package variables are public. The same result is achieved with the `#export on` modifier.
- If the package contains the `#export` modifier with specified variables, these variables are public, while all other package variables are private.
- The `#export` modifier can be used several times in the `__init__` function, and all the specified variables are considered public.
- The `#export off` modifier means no variables should be public, and specifying exported variables in this case will result in error.
- The `#export on` modifier renders all the variables public, and using the `#export` modifier again will result in error.

- The `#export` modifer must contain at least one variable.
- Private variables can only be used inside the package that specifies them. They can be called from functions and procedures from the package with the `#package` modifier. If they are declared separately, the package name must be specified.
- Public variables can be used both inside and outside the package in case functions, procedures and anonymous blocks have the `#import` modifier that specifies the package name.

L.1.2. Built-in Functions

PL/pgSQL provides a built-in function `plpgsql_reset_packages()` that deinstantiates all the packages in this session to bring the session to the original state.

```
SELECT plpgsql_reset_packages();
```

L.1.3. SQL Commands

You can work with packages using regular schema-oriented commands (like `CREATE SCHEMA` and `DROP SCHEMA`) with function modifiers but `CREATE OR REPLACE PACKAGE` and `DROP PACKAGE` commands are more convenient.

L.1.3.1. `CREATE OR REPLACE PACKAGE`

`CREATE OR REPLACE PACKAGE` will either create a new package, or replace the existing definition.

```
CREATE [OR REPLACE] PACKAGE package_name package_body;
```

Here *`package_name`* is the name of the schema, and *`package_body`* is the set of package creation commands with several caveats to be aware of:

- The `CREATE SCHEMA` is executed automatically.
- The `#package` modifier can be omitted — all the functions are modified automatically.
- No language is specified when creating functions.
- Function and type names are specified without the package name.
- The individual top-level subcommands in the package body do not end with semicolons.
- The package name must be distinct from the name of any existing package or schema in the current database.

The example below shows how the package can be created using the `CREATE SCHEMA` command.

```
CREATE SCHEMA foo;
CREATE TYPE foo.footype AS (a int, b int);
CREATE FUNCTION foo.__init__() RETURNS void AS $$
DECLARE x int := 1;
BEGIN
  RAISE NOTICE 'foo initialized';
END;
$$ LANGUAGE plpgsql;

CREATE FUNCTION foo.get() RETURNS int AS $$
#package
BEGIN
  RETURN x;
END;
$$ LANGUAGE plpgsql;

CREATE FUNCTION foo.inc() returns void AS $$
#package
BEGIN
```

```
  x := x + 1;
END;
$$ LANGUAGE plpgsql;
```

The following is an equivalent way of achieving the same result using the `CREATE PACKAGE` command:

```
CREATE PACKAGE foo
  CREATE TYPE footype AS (a int, b int)

  CREATE FUNCTION __init__() RETURNS void AS $$
  DECLARE
    x int := 1;
  BEGIN
    RAISE NOTICE 'foo initialized';
  END;
  $$

  CREATE FUNCTION get() RETURNS int AS $$
  BEGIN
    RETURN x;
  END;
  $$

  CREATE FUNCTION inc() RETURNS void AS $$
  BEGIN
    x := x + 1;
  ENG;
  $$
;
```

You can replace the existing package with the following special considerations:

- You can use the `CREATE OR REPLACE PACKAGE` to replace only schemas that are packages (i.e. containing only functions and composite types and the initialization function).
- When any elements of the old package are not defined in the new package, they are dropped if there are no dependent objects, otherwise the `CREATE OR REPLACE PACKAGE` is forced to fail.
- If you replace the package without changing the function signature, its body is replaced, while dependent objects still remain. If the function signature changes, you would actually be creating a new, distinct function. The latter would only work when there are no dependent objects, otherwise the `CREATE OR REPLACE PACKAGE` is forced to fail.
- The same restriction applies to replacing types.
- If the command fails due to existing dependent objects, the containing package is referenced by the error rather than the objects themselves.

`CREATE OR REPLACE PACKAGE` is a fully transactional command so any mistakes when defining package elements would cause it to fail entirely, and all the changes are discarded.

L.1.3.2. DROP PACKAGE

`DROP PACKAGE` removes packages (schemas) from the database along with dependent objects.

```
DROP PACKAGE [IF EXISTS] package_name_list [CASCADE];
```

Here *`package_name_list`* is the list of packages to be dropped. The command is fully transactional so either all of the packages are dropped, or none if the command fails. This command is similar to `DROP SCHEMA` with several caveats to be aware of:

- You can use `DROP PACKAGE` to drop only schemas that are packages (i.e. containing only functions and composite types and the initialization function).

- If the command fails due to existing dependent objects, the containing package is referenced by the error rather than the objects themselves.
- Using the `CASCADE` option might make the command find objects to be removed in other packages besides the one(s) named. In this case, other packages are dropped as well.

All the dependencies mentioned in this section are standard Postgres Pro dependencies (see Section 5.14). For example, if a function uses other function signature in its own definition, the dependency is created but a single function call does not create one. When a function accesses package variables from outside the package, no dependency is created either (even a getter function).

L.1.4. Limitations

- In Oracle, a package is an atomic structure that can be modified only as a whole with `CREATE OR REPLACE`. As far as Postgres Pro Enterprise is concerned, a package is a schema so its elements can be modified separately with `CREATE OR REPLACE PROCEDURE`, `CREATE OR REPLACE FUNCTION`, or `ALTER TYPE`. Thus, you can easily replace a function or a type that does not have dependencies rather than replace the package itself. If you replace the package, you also need to replace all the dependent packages and functions manually.
- Since a package in Postgres Pro is a schema, the user should have the rights on the schema:

  ```
  GRANT USAGE ON SCHEMA foo, bar TO hr_user;
  ```

  If the package must be run with definer's rights, the user should have all the rights on the schema:

  ```
  GRANT ALL ON SCHEMA hr_main TO hr_user;
  ```

  If the package must be run with invoker's rights, the user should have specific rights on tables and views to be used in the package, for example:

  ```
  GRANT SELECT demo.employee_tab TO hr_user;
  ```
- Unlike Oracle, which stores all the information about package dependencies and in general about all PL/SQL objects (triggers, functions, procedures, etc.), Postgres Pro doesn't store dependencies at the level of function body and variables so these dependencies cannot be tracked when the package changes.
- In Oracle, when the dependencies are broken, the package becomes `INVALID`. In this case, the package still exists in the database but it is not working. Unlike that, in Postgres Pro any object created or modified in the database must be valid. So if any operation in Postgres Pro leads to package invalidation (for example, the table used in package type declaration is dropped), it cannot be executed — first, the package must be deleted as it cannot remain invalid in the database.
- When modifying packages, make sure that no other sessions use them (which can be done by stopping the application before replacing the packages). Once done, restart the application, and updated package versions will be available in all the sessions. This limitation is caused by the lack of library cache in Postgres Pro (unlike Oracle) since each backend caches PL/pgSQL code. If the package is modified in one session, and another session still works with the old package version, it would cause inconsistency, especially if the list of global package variables changes. Currently there are no global locks for package modification (like latch in Oracle) and no package modification tracking (like “ORA-04068: existing state of packages has been discarded” in Oracle).
- Unlike Oracle, packages are not separated into specification and body.
- Clauses modifying procedure declaration (like `RESULT_CACHE`, `DETERMINISTIC` in Oracle) are not supported. PL/SQL compiler directives are not supported either (like `INLINE` pragma, `UDF` pragma, etc.).

L.2. Package Export Using ora2pgpro

ora2pgpro is a utility based on the ora2pg application, which can be used for porting Oracle packages and autonomous transactions as Postgres Pro packages and autonomous transactions when migrating an Oracle database to a Postgres Pro-compatible schema. ora2pgpro properly extracts type and variable declarations from the package body and specification, including the initialization section. Moreover,

ora2pgpro exports autonomous transactions directly as opposed to ora2pg's translation of autonomous transactions into wrapper functions using dblink or pg_background extensions. It's worth noting that autonomous transactions are syntactically very different in Oracle and Postgres Pro. Currently, circular dependencies of packages are not supported.

To export packages using ora2pgpro, first edit the `ora2pgpro.conf` file.

- Configure settings to control the access to the Oracle database.

```
ORACLE_HOME "my_oracle_home_dir"
ORACLE_DSN dbi:Oracle:host=localhost;sid=MY_SID;port=1521
ORACLE_USER USER
ORACLE_PWD PASSWORD
SCHEMA SCHEMA
```

- Optionally, you can set the `TYPE` variable to `PACKAGE`. Note that you can also set the type of export when running ora2pgpro as shown in the example below.
- If you want to export autonomous transactions directly as Postgres Pro Enterprise autonomous transactions, set `POSTGRESPRO_ATX` to 1. Note that this disables the `AUTONOMOUS_TRANSACTION` parameter responsible for translation of autonomous transactions into a wrapper function.

```
POSTGRESPRO_ATX 1
```

- If you want to export only some packages, list them separated by commas in the `INCLUDE_PACKAGES` parameter, or specify the unwanted packages names in the `EXCLUDE_PACKAGES` parameter.

```
INCLUDE_PACKAGES 'PKG_A', 'PKG_B'
```

Now you can run ora2pgpro.

```
ora2pgpro -t PACKAGE -c ora2pgpro.conf -o packages.sql
```

A short example below shows how the `CUSTOMER_PKG` package can be ported using ora2pgpro. This is the Oracle version:

```
CREATE OR REPLACE PACKAGE customer_pkg IS

  gBatchSize constant integer := 100;

  type
    TCustomerInfo is record
    (
      Id          number(9,0),
      Name        varchar2(32 char),
      Description varchar2(512 char)
    );

  type
    TBuffer is table of TCustomerInfo index by pls_integer;
  v_gBuffer TBuffer;

  v_cMainCustomer constant number(9,0) := 1;

  v_gCurrentCustomerId number(9,0);

...

  PROCEDURE dump(v_pCustomer in out nocopy TCustomerInfo);

  PROCEDURE init_package;
END;
```

```
CREATE OR REPLACE PACKAGE BODY customer_pkg IS

...

  PROCEDURE dump(v_pCustomer in out nocopy TCustomerInfo) IS
  BEGIN
    console.log('------------------  Dump of customer_pkg.TCustomerInfo
 ------------------------');
    console.log('Id          => ' || v_pCustomer.Id);
    console.log('Name        => ' || v_pCustomer.Name);
    console.log('Description => ' || v_pCustomer.Description);

 console.log('-------------------------------------------------------------------------------
  END;

  PROCEDURE init_package IS
  BEGIN
    v_gCurrentCustomerId := 0;
  END;

BEGIN
  init_package();
END;
```

Here is how this package would end up in Postgres Pro:

```
-- Oracle package 'CUSTOMER_PKG' declaration, edit to match PostgreSQL syntax

DROP SCHEMA IF EXISTS customer_pkg CASCADE;
CREATE SCHEMA IF NOT EXISTS customer_pkg;
CREATE TYPE customer_pkg.tcustomerinfo AS (
Id          integer,
      Name        varchar(32),
      Description varchar(512)

);

CREATE TYPE customer_pkg.tbuffer AS (tbuffer CUSTOMER_PKG.TCustomerInfo[]);

CREATE OR REPLACE FUNCTION customer_pkg.__init__ () RETURNS VOID AS $body$
#import CONSOLE
DECLARE

 gBatchSize constant integer := 100;
 v_gBuffer CUSTOMER_PKG.TBuffer;
 v_cMainCustomer constant integer := 1;
 v_gCurrentCustomerId integer;

BEGIN
  CALL customer_pkg.init_package();
end;

$body$
LANGUAGE PLPGSQL
SECURITY DEFINER
;
-- REVOKE ALL ON FUNCTION customer_pkg.__init__ () FROM PUBLIC;
```

```
CREATE OR REPLACE PROCEDURE customer_pkg.init_package () AS $body$
#package
BEGIN
    v_gCurrentCustomerId := 0;
  end;
$body$
LANGUAGE PLPGSQL
SECURITY DEFINER
;
-- REVOKE ALL ON PROCEDURE customer_pkg.init_package () FROM PUBLIC;

CREATE OR REPLACE PROCEDURE customer_pkg.dump (v_pCustomer INOUT
 CUSTOMER_PKG.TCustomerInfo) AS $body$
#package
BEGIN
    CALL console.log('------------------  Dump of customer_pkg.TCustomerInfo
 ------------------------');
    CALL console.log('Id          => ' || v_pCustomer.Id);
    CALL console.log('Name        => ' || v_pCustomer.Name);
    CALL console.log('Description => ' || v_pCustomer.Description);
    CALL
 console.log('-------------------------------------------------------------------------------
  end;
$body$
LANGUAGE PLPGSQL
SECURITY DEFINER
;
-- REVOKE ALL ON PROCEDURE customer_pkg.dump (v_pCustomer INOUT
 CUSTOMER_PKG.TCustomerInfo) FROM PUBLIC;
```

Complete package examples are available at *ora2pgpro.postgrespro.ru*. The scripts are distributed under the *PostgreSQL license*. See also the *ora2pgpro documentation*.

L.3. Script Parameters

Postgres Pro provides the ability to pass named and positional parameters for script execution. For more information, see the `\i` command on the psql reference page.

Appendix M. Postgres Pro Limits

Table M.1 describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

Table M.1. Postgres Pro Limitations

Item	Upper Limit	Comment
database size	unlimited	
number of databases	4,294,950,911	
relations per database	1,431,650,303	
relation size	32 TB	with the default `BLCKSZ` of 8192 bytes
rows per table	limited by the number of tuples that can fit onto 4,294,967,295 pages	
columns per table	1,600	further limited by tuple size fitting on a single page; see note below
columns in a result set	1,664	
field size	1 GB	
indexes per table	unlimited	constrained by maximum relations per database
columns per index	32	can be increased by recompiling Postgres Pro
partition keys	32	can be increased by recompiling Postgres Pro
identifier length	63 bytes	can be increased by recompiling Postgres Pro
function arguments	100	can be increased by recompiling Postgres Pro
query parameters	65,535	

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

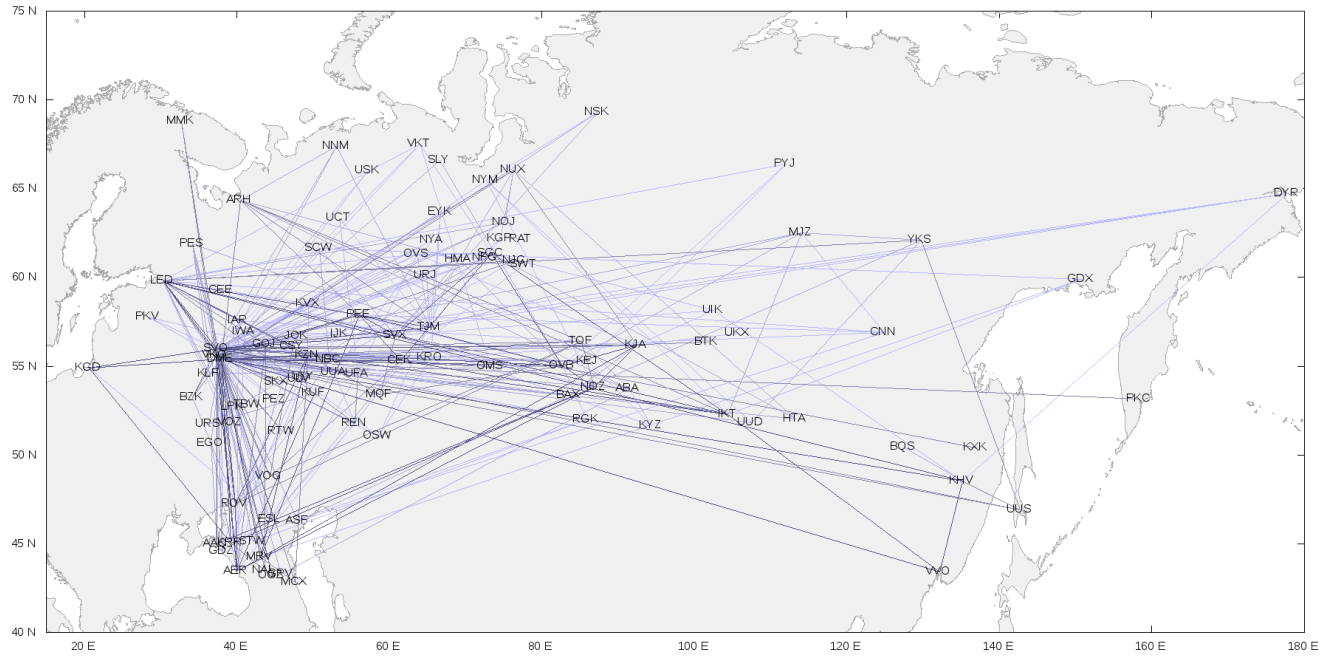
Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Each table can store a theoretical maximum of 2^32 out-of-line values; see Section 74.2 for a detailed discussion of out-of-line storage. This limit arises from the use of a 32-bit OID to identify each such value. The practical limit is significantly less than the theoretical limit, because as the OID space fills up, finding an OID that is still free can become expensive, in turn slowing down INSERT/UPDATE statements. Typically, this is only an issue for tables containing many terabytes of data; partitioning is a possible workaround.

Appendix N. Demo Database “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from *our website*. See Section N.1 for details.

Figure N.1. Airlines in Russia



You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the *PostgreSQL license*.

You can send us your feedback to *edu@postgrespro.ru*.

N.1. Installation

The demo database is available at *edu.postgrespro.com* in three flavors, which differ only in the data size:

- *demo-small-en.zip* (21 MB) — flight data for one month (DB size is about 300 MB)
- *demo-medium-en.zip* (62 MB) — flight data for three months (DB size is about 700 MB)
- *demo-big-en.zip* (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

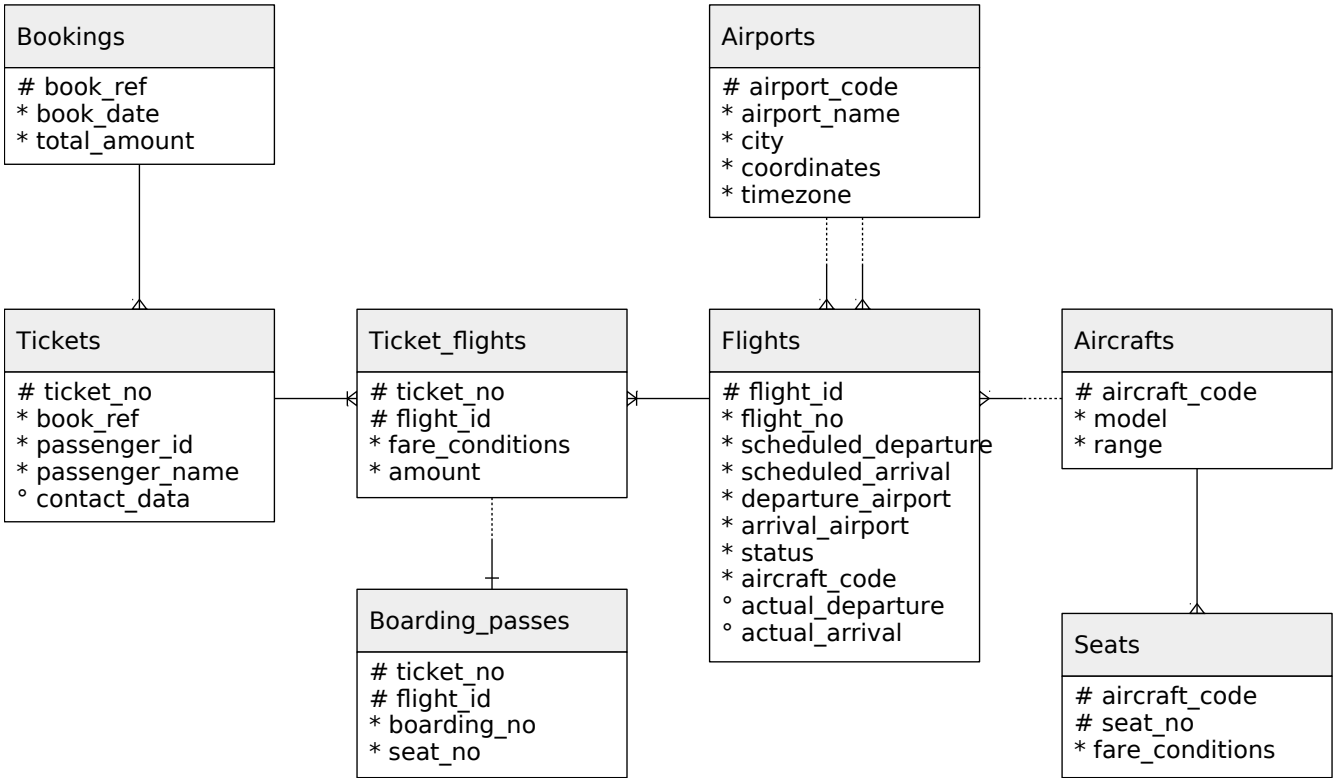
The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the pg_dump utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of psql:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

N.2. Schema Diagram

Figure N.2. Bookings Schema Diagram



N.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

N.4. Schema Objects

N.4.1. List of Relations

```
       Name       |     Type      |  Small  | Medium |   Big   |       Description
------------------+---------------+---------+--------+---------+-------------------------
 aircrafts        | view          |         |        |         | Aircraft
 aircrafts_data   | table         |  16 kB  |  16 kB |  16 kB  | Aircraft (translations)
 airports         | view          |         |        |         | Airports
 airports_data    | table         |  56 kB  |  56 kB |  56 kB  | Airports (translations)
 boarding_passes  | table         |  31 MB  | 102 MB | 427 MB  | Boarding passes
 bookings         | table         |  13 MB  |  30 MB | 105 MB  | Bookings

 seats            | table         |  88 kB  |  88 kB |  88 kB  | Seats
 ticket_flights   | table         |  64 MB  | 145 MB | 516 MB  | Flight segments
 tickets          | table         |  47 MB  | 107 MB | 381 MB  | Tickets
```

N.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See Section N.4.15 for details.

```
    Column     |  Type   | Modifiers |             Description
---------------+---------+-----------+-------------------------------------
 aircraft_code | char(3) | not null  | Aircraft code, IATA
 model         | text    | not null  | Aircraft model
 range         | integer | not null  | Maximal flying distance, km
View definition:
 SELECT ml.aircraft_code,
    ml.model ->> lang() AS model,
    ml.range
   FROM aircrafts_data ml;
```

N.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

```
    Column     |  Type   | Modifiers |             Description
---------------+---------+-----------+-------------------------------------
 aircraft_code | char(3) | not null  | Aircraft code, IATA
```

```
 model         | jsonb   | not null     | Aircraft model
 range         | integer | not null     | Maximal flying distance, km
Indexes:
    PRIMARY KEY, btree (aircraft_code)
Check constraints:
    CHECK (range > 0)
Referenced by:
    TABLE "flights" FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts_data(aircraft_code)
    TABLE "seats" FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE
```

N.4.4. View `bookings.airports`

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See Section N.4.15 for details.

```
   Column     |  Type   | Modifiers    |                 Description
--------------+---------+--------------+---------------------------------------------
 airport_code | char(3) | not null     | Airport code
 airport_name | text    | not null     | Airport name
 city         | text    | not null     | City
 coordinates  | point   | not null     | Airport coordinates (longitude and latitude)
 timezone     | text    | not null     | Airport time zone
View definition:
 SELECT ml.airport_code,
    ml.airport_name ->> lang() AS airport_name,
    ml.city ->> lang() AS city,
    ml.coordinates,
    ml.timezone
   FROM airports_data ml;
```

N.4.5. Table `bookings.airports_data`

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

```
   Column     |  Type   | Modifiers    |                 Description
--------------+---------+--------------+---------------------------------------------
 airport_code | char(3) | not null     | Airport code
 airport_name | jsonb   | not null     | Airport name
 city         | jsonb   | not null     | City
 coordinates  | point   | not null     | Airport coordinates (longitude and latitude)
 timezone     | text    | not null     | Airport time zone
Indexes:
    PRIMARY KEY, btree (airport_code)
Referenced by:
    TABLE "flights" FOREIGN KEY (arrival_airport)
        REFERENCES airports_data(airport_code)
    TABLE "flights" FOREIGN KEY (departure_airport)
        REFERENCES airports_data(airport_code)
```

N.4.6. Table bookings.boarding_passes

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (boarding_no), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (seat_no).

```
   Column    |    Type    | Modifiers    |         Description
-------------+------------+--------------+-------------------------
 ticket_no   | char(13)   | not null     | Ticket number
 flight_id   | integer    | not null     | Flight ID
 boarding_no | integer    | not null     | Boarding pass number
 seat_no     | varchar(4) | not null     | Seat number
Indexes:
    PRIMARY KEY, btree (ticket_no, flight_id)
    UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
    UNIQUE CONSTRAINT, btree (flight_id, seat_no)
Foreign-key constraints:
    FOREIGN KEY (ticket_no, flight_id)
        REFERENCES ticket_flights(ticket_no, flight_id)
```

N.4.7. Table bookings.bookings

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (book_date, not earlier than one month before the flight). The booking is identified by its number (book_ref, a six-position combination of letters and digits).

The total_amount field stores the total cost of all tickets included into the booking, for all passengers.

```
   Column     |      Type     | Modifiers    |         Description
--------------+---------------+--------------+-------------------------
 book_ref     | char(6)       | not null     | Booking number
 book_date    | timestamptz   | not null     | Booking date
 total_amount | numeric(10,2) | not null     | Total booking cost
Indexes:
    PRIMARY KEY, btree (book_ref)
Referenced by:
    TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

N.4.8. Table bookings.flights

The natural key of the bookings.flights table consists of two fields — flight_no and scheduled_departure. To make foreign keys for this table more compact, a surrogate key is used as the primary key (flight_id).

A flight always connects two points — the airport of departure (departure_airport) and arrival (arrival_airport). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (scheduled_departure) and arrival (scheduled_arrival). The actual departure time (actual_departure) and arrival time (actual_arrival) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

Flight status (`status`) can take one of the following values:

`Scheduled`

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

`On Time`

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

`Delayed`

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

`Departed`

The aircraft has already departed and is airborne.

`Arrived`

The aircraft has reached the point of destination.

`Cancelled`

The flight is canceled.

```
        Column       |     Type    | Modifiers    |         Description
---------------------+-------------+--------------+-----------------------------
 flight_id           | serial      | not null     | Flight ID
 flight_no           | char(6)     | not null     | Flight number
 scheduled_departure | timestamptz | not null     | Scheduled departure time
 scheduled_arrival   | timestamptz | not null     | Scheduled arrival time
 departure_airport   | char(3)     | not null     | Airport of departure
 arrival_airport     | char(3)     | not null     | Airport of arrival
 status              | varchar(20) | not null     | Flight status
 aircraft_code       | char(3)     | not null     | Aircraft code, IATA
 actual_departure    | timestamptz |              | Actual departure time
 actual_arrival      | timestamptz |              | Actual arrival time
Indexes:
    PRIMARY KEY, btree (flight_id)
    UNIQUE CONSTRAINT, btree (flight_no, scheduled_departure)
Check constraints:
    CHECK (scheduled_arrival > scheduled_departure)
    CHECK ((actual_arrival IS NULL)
       OR  ((actual_departure IS NOT NULL AND actual_arrival IS NOT NULL)
            AND (actual_arrival > actual_departure)))
    CHECK (status IN ('On Time', 'Delayed', 'Departed',
                      'Arrived', 'Scheduled', 'Cancelled'))
Foreign-key constraints:
    FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts(aircraft_code)
    FOREIGN KEY (arrival_airport)
        REFERENCES airports(airport_code)
    FOREIGN KEY (departure_airport)
        REFERENCES airports(airport_code)
Referenced by:
    TABLE "ticket_flights" FOREIGN KEY (flight_id)
        REFERENCES flights(flight_id)
```

N.4.9. Table `bookings.seats`

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): `Economy`, `Comfort` or `Business`.

```
      Column     |     Type    | Modifiers    |      Description
-----------------+-------------+--------------+--------------------
 aircraft_code   | char(3)     | not null     | Aircraft code, IATA
 seat_no         | varchar(4)  | not null     | Seat number
 fare_conditions | varchar(10) | not null     | Travel class
Indexes:
    PRIMARY KEY, btree (aircraft_code, seat_no)
Check constraints:
    CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
Foreign-key constraints:
    FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE
```

N.4.10. Table `bookings.ticket_flights`

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

```
     Column      |     Type      | Modifiers    |    Description
-----------------+---------------+--------------+--------------------
 ticket_no       | char(13)      | not null     | Ticket number
 flight_id       | integer       | not null     | Flight ID
 fare_conditions | varchar(10)   | not null     | Travel class
 amount          | numeric(10,2) | not null     | Travel cost
Indexes:
    PRIMARY KEY, btree (ticket_no, flight_id)
Check constraints:
    CHECK (amount >= 0)
    CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
Foreign-key constraints:
    FOREIGN KEY (flight_id) REFERENCES flights(flight_id)
    FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
Referenced by:
    TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
        REFERENCES ticket_flights(ticket_no, flight_id)
```

N.4.11. Table `bookings.tickets`

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

```
     Column     |     Type    | Modifiers    |          Description
----------------+-------------+--------------+---------------------------
 ticket_no      | char(13)    | not null     | Ticket number
 book_ref       | char(6)     | not null     | Booking number
 passenger_id   | varchar(20) | not null     | Passenger ID
 passenger_name | text        | not null     | Passenger name
```

```
 contact_data   | jsonb       |             | Passenger contact information
Indexes:
    PRIMARY KEY, btree (ticket_no)
Foreign-key constraints:
    FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
Referenced by:
    TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

N.4.12. View `bookings.flights_v`

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

```
          Column           |    Type     |              Description
---------------------------+-------------+---------------------------------------
 flight_id                 | integer     | Flight ID
 flight_no                 | char(6)     | Flight number
 scheduled_departure       | timestamptz | Scheduled departure time
 scheduled_departure_local | timestamp   | Scheduled departure time,
                           |             | local time at the point of departure
 scheduled_arrival         | timestamptz | Scheduled arrival time
 scheduled_arrival_local   | timestamp   | Scheduled arrival time,
                           |             | local time at the point of destination
 scheduled_duration        | interval    | Scheduled flight duration
 departure_airport         | char(3)     | Departure airport code
 departure_airport_name    | text        | Departure airport name
 departure_city            | text        | City of departure
 arrival_airport           | char(3)     | Arrival airport code
 arrival_airport_name      | text        | Arrival airport name
 arrival_city              | text        | City of arrival
 status                    | varchar(20) | Flight status
 aircraft_code             | char(3)     | Aircraft code, IATA
 actual_departure          | timestamptz | Actual departure time
 actual_departure_local    | timestamp   | Actual departure time,
                           |             | local time at the point of departure
 actual_arrival            | timestamptz | Actual arrival time
 actual_arrival_local      | timestamp   | Actual arrival time,
                           |             | local time at the point of destination
 actual_duration           | interval    | Actual flight duration
```

N.4.13. View `bookings.routes`

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

```
        Column          |   Type    |             Description
```

```
------------------------+-----------+--------------------------------------
 flight_no              | char(6)   | Flight number
 departure_airport      | char(3)   | Departure airport code
 departure_airport_name | text      | Departure airport name
 departure_city         | text      | City of departure
 arrival_airport        | char(3)   | Arrival airport code
 arrival_airport_name   | text      | Arrival airport name
 arrival_city           | text      | City of arrival
 aircraft_code          | char(3)   | Aircraft code, IATA
 duration               | interval  | Flight duration
 days_of_week           | integer[] | Days of the week on which flights are performed
```

N.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

N.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the *`bookings.lang`* parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

N.5. Usage

N.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

N.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the *`bookings.lang`* parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see Section 19.1.

In the examples below, the English language is selected for translatable fields.

N.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

```
 aircraft_code |        model         | range
---------------+----------------------+-------
 773           | Boeing 777-300       | 11100
 763           | Boeing 767-300       |  7900
 SU9           | Sukhoi SuperJet-100  |  3000
 320           | Airbus A320-200      |  5700
 321           | Airbus A321-200      |  5600
 319           | Airbus A319-100      |  6700
 733           | Boeing 737-300       |  4200
 CN1           | Cessna 208 Caravan   |  1200
 CR2           | Bombardier CRJ-200   |  2700
(9 rows)
```

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT   a.aircraft_code,
         a.model,
         s.seat_no,
         s.fare_conditions
FROM     aircrafts a
         JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE    a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

```
 aircraft_code |       model        | seat_no | fare_conditions
---------------+--------------------+---------+-----------------
 CN1           | Cessna 208 Caravan | 1A      | Economy
 CN1           | Cessna 208 Caravan | 1B      | Economy
 CN1           | Cessna 208 Caravan | 2A      | Economy
 CN1           | Cessna 208 Caravan | 2B      | Economy
 CN1           | Cessna 208 Caravan | 3A      | Economy
 CN1           | Cessna 208 Caravan | 3B      | Economy
 CN1           | Cessna 208 Caravan | 4A      | Economy
 CN1           | Cessna 208 Caravan | 4B      | Economy
 CN1           | Cessna 208 Caravan | 5A      | Economy
 CN1           | Cessna 208 Caravan | 5B      | Economy
 CN1           | Cessna 208 Caravan | 6A      | Economy
 CN1           | Cessna 208 Caravan | 6B      | Economy
(12 rows)
```

Bigger aircraft have more seats of various travel classes:

```
SELECT   s2.aircraft_code,
```

```
         string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
                     ', ') as fare_conditions
FROM     (
          SELECT   s.aircraft_code, s.fare_conditions, count(*) as num
          FROM     seats s
          GROUP BY s.aircraft_code, s.fare_conditions
          ORDER BY s.aircraft_code, s.fare_conditions
         ) s2
GROUP BY s2.aircraft_code
ORDER BY s2.aircraft_code;
```

```
 aircraft_code |             fare_conditions
---------------+-----------------------------------------
 319           | Business(20), Economy(96)
 320           | Business(20), Economy(120)
 321           | Business(28), Economy(142)
 733           | Business(12), Economy(118)
 763           | Business(30), Economy(192)
 773           | Business(30), Comfort(48), Economy(324)
 CN1           | Economy(12)
 CR2           | Economy(50)
 SU9           | Business(12), Economy(85)
(9 rows)
```

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```
SELECT   a.airport_code as code,
         a.airport_name,
         a.city,
         a.coordinates
FROM     airports a
WHERE    a.city IN (
            SELECT   aa.city
            FROM     airports aa
            GROUP BY aa.city
            HAVING   COUNT(*) > 1
         )
ORDER BY a.city, a.airport_code;
```

```
 code |      airport_name      |   city    |           coordinates
------+------------------------+-----------+-------------------------
 DME  | Domodedovo             | Moscow    | (37.9062995910645,55.4087982177734)
      | International Airport  |           |
 SVO  | Sheremetyevo           | Moscow    | (37.4146,55.972599)

(5 rows)
```

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = 'Volgograd';
```

```
    city     | code |            airport_name             |  days_of_week   | duration
-------------+------+-------------------------------------+-----------------+----------
 Moscow      | SVO  | Sheremetyevo International Airport | {1,2,3,4,5,6,7} | 01:15:00
 Chelyabinsk | CEK  | Chelyabinsk Balandino Airport      | {1,2,3,4,5,6,7} | 01:50:00
 Rostov      | ROV  | Rostov-on-Don Airport              | {1,2,3,4,5,6,7} | 00:30:00
 Moscow      | VKO  | Vnukovo International Airport      | {1,2,3,4,5,6,7} | 01:10:00
 Cheboksary  | CSY  | Cheboksary Airport                 | {1,2,3,4,5,6,7} | 02:45:00
 Tomsk       | TOF  | Bogashevo Airport                  | {1}             | 03:50:00
(6 rows)
```

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

```
          now
------------------------
 2017-08-15 18:00:00+03
```

In relation to this moment, all flights are classified as past and future flights:

```
SELECT   status,
         count(*) as count,
         min(scheduled_departure) as min_scheduled_departure,
         max(scheduled_departure) as max_scheduled_departure
FROM     flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

```
  status   | count | min_scheduled_departure | max_scheduled_departure
-----------+-------+-------------------------+-------------------------
 Arrived   | 16707 | 2017-07-16 01:50:00+03  | 2017-08-15 17:25:00+03
 Cancelled |   414 | 2017-07-19 11:35:00+03  | 2017-09-14 20:55:00+03
 Departed  |    58 | 2017-08-15 09:55:00+03  | 2017-08-15 17:50:00+03
 Delayed   |    41 | 2017-08-15 15:15:00+03  | 2017-08-16 17:25:00+03
 On Time   |   518 | 2017-08-15 17:55:00+03  | 2017-08-16 18:00:00+03
 Scheduled | 15383 | 2017-08-16 18:05:00+03  | 2017-09-14 20:40:00+03
(6 rows)
```

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT   f.*
FROM     flights_v f
WHERE    f.departure_city = 'Yekaterinburg'
AND      f.arrival_city = 'Moscow'
```

```
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT    1;
```

```
-[ RECORD 1 ]------------+---------------------------------
flight_id                | 10927
flight_no                | PG0226
scheduled_departure      | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival        | 2017-08-16 09:55:00+03
scheduled_arrival_local  | 2017-08-16 09:55:00
scheduled_duration       | 01:45:00
departure_airport        | SVX
departure_airport_name   | Koltsovo Airport
departure_city           | Yekaterinburg
arrival_airport          | SVO
arrival_airport_name     | Sheremetyevo International Airport
arrival_city             | Moscow
status                   | On Time
aircraft_code            | 773
actual_departure         |
actual_departure_local   |
actual_arrival           |
actual_arrival_local     |
actual_duration          |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

N.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT   *
FROM     bookings
ORDER BY total_amount desc
LIMIT    10;
```

```
 book_ref |       book_date        | total_amount
----------+------------------------+--------------
 3B54BB   | 2017-07-05 17:08:00+03 |   1204500.00
 3AC131   | 2017-07-31 01:06:00+03 |   1087100.00
 65A6EA   | 2017-07-03 06:28:00+03 |   1065600.00
 D7E9AA   | 2017-08-08 05:29:00+03 |   1062800.00
 EF479E   | 2017-08-02 15:58:00+03 |   1035100.00
 521C53   | 2017-07-08 09:25:00+03 |    985500.00
 514CA6   | 2017-07-27 05:07:00+03 |    955000.00
 D70BD9   | 2017-07-05 12:47:00+03 |    947500.00
 EC7EDA   | 2017-07-02 16:13:00+03 |    946800.00
 8E4370   | 2017-07-28 02:04:00+03 |    945700.00
(10 rows)
```

Let's take a look at the tickets included into the booking with code `521C53`:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

```
   ticket_no   | passenger_id |   passenger_name
---------------+--------------+--------------------
 0005432661914 | 8234 547529  | IVAN IVANOV
 0005432661915 | 2034 201228  | ANTONINA KUZNECOVA
(2 rows)
```

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT   to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
         f.departure_city || ' (' || f.departure_airport || ')' AS departure,
         f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
         tf.fare_conditions AS class,
         tf.amount
FROM     ticket_flights tf
         JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE    tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

```
    when    |      departure       |       arrival        |  class   |  amount
------------+----------------------+----------------------+----------+-----------
 29.07.2017 | Moscow (SVO)         | Anadyr (DYR)         | Business | 185300.00
 02.08.2017 | Anadyr (DYR)         | Khabarovsk (KHV)     | Business |  92200.00
 03.08.2017 | Khabarovsk (KHV)     | Blagoveshchensk (BQS)| Business |  18000.00
 08.08.2017 | Blagoveshchensk (BQS)| Khabarovsk (KHV)     | Business |  18000.00
 12.08.2017 | Khabarovsk (KHV)     | Anadyr (DYR)         | Economy  |  30700.00
 17.08.2017 | Anadyr (DYR)         | Moscow (SVO)         | Business | 185300.00
(6 rows)
```

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT   to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
         f.departure_city || ' (' || f.departure_airport || ')' AS departure,
         f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
         f.status,
         bp.seat_no
FROM     ticket_flights tf
         JOIN flights_v f ON tf.flight_id = f.flight_id
         LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                     AND tf.ticket_no = bp.ticket_no
WHERE    tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

```
    when    |      departure       |       arrival        |  status   | seat_no
------------+----------------------+----------------------+-----------+---------
```

```
 29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Arrived   | 5C
 02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Arrived   | 1D
 03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS)| Arrived   | 2C
 08.08.2017 | Blagoveshchensk (BQS)| Khabarovsk (KHV)      | Arrived   | 2D
 12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Arrived   | 20B
 17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Scheduled |
(6 rows)
```

N.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_000000000001', 8525, 'Business', 0),
            ('_000000000001', 4967, 'Business', 0);

COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```
INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_000000000001', 8525, 1, '1A');
```

Now let's check the booking information:

```
SELECT   b.book_ref,
         t.ticket_no,
         t.passenger_id,
         t.passenger_name,
         tf.fare_conditions,
         tf.amount,
         f.scheduled_departure_local,
         f.scheduled_arrival_local,
         f.departure_city || ' (' || f.departure_airport || ')' AS departure,
         f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
         f.status,
         bp.seat_no
FROM     bookings b
         JOIN tickets t ON b.book_ref = t.book_ref
         JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
         JOIN flights_v f ON tf.flight_id = f.flight_id
         LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                     AND tf.ticket_no = bp.ticket_no
WHERE    b.book_ref = '_QWE12'
```

```
ORDER BY t.ticket_no, f.scheduled_departure;

-[ RECORD 1 ]-------------+--------------------
book_ref                  | _QWE12
ticket_no                 | _000000000001
passenger_id              | 1749 051790
passenger_name            | ALEKSANDR RADISHCHEV
fare_conditions           | Business
amount                    | 0.00
scheduled_departure_local | 2017-08-16 09:45:00
scheduled_arrival_local   | 2017-08-16 10:35:00
departure                 | St. Petersburg (LED)
arrival                   | Moscow (SVO)
status                    | On Time
seat_no                   | 1A
-[ RECORD 2 ]-------------+--------------------
book_ref                  | _QWE12
ticket_no                 | _000000000001
passenger_id              | 1749 051790
passenger_name            | ALEKSANDR RADISHCHEV
fare_conditions           | Business
amount                    | 0.00
scheduled_departure_local | 2017-08-23 10:20:00
scheduled_arrival_local   | 2017-08-23 11:10:00
departure                 | Moscow (SVO)
arrival                   | St. Petersburg (LED)
status                    | Scheduled
seat_no                   |
```

We hope that these simple examples helped you get an idea of this demo database.

Appendix O. Acronyms

This is a list of acronyms commonly used in the Postgres Pro documentation and in discussions about Postgres Pro.

ANSI

American National Standards Institute

Appendix P. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

ACID
: *Atomicity*, *Consistency*, *Isolation*, and *Durability*. This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.

Aggregate function (routine)
: A *function* that combines (*aggregates*) multiple input values, for example by counting, averaging or adding, yielding a single output value.

  For more information, see Section 9.21.

  See Also Window function (routine).

Analytic function
: See Window function (routine).

Analyze (operation)
: The act of collecting statistics from data in *tables* and other *relations* to help the *query planner* to make decisions about how to execute *queries*.

  (Don't confuse this term with the `ANALYZE` option to the EXPLAIN command.)

  For more information, see ANALYZE.

Atomic
: In reference to a *datum*: the fact that its value cannot be broken down into smaller components.

  In reference to a *database transaction*: see *atomicity*.

Atomicity
: The property of a *transaction* that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.

Attribute
: An element with a certain name and data type found within a *tuple*.

Autovacuum (process)
: A set of background processes that routinely perform *vacuum* and *analyze* operations. The *auxiliary process* that coordinates the work and is always present (unless autovacuum is disabled) is known as the *autovacuum launcher*, and the processes that carry out the tasks are known as the *autovacuum workers*.

  For more information, see Section 24.1.6.

Auxiliary process
: A process within an *instance* that is in charge of some specific background task for the instance. The auxiliary processes consist of the *autovacuum launcher* (but not the autovacuum workers), the *background writer*, the *checkpointer*, the *logger*, the *startup process*, the *WAL archiver*, the *WAL receiver* (but not the *WAL senders*), and the *WAL writer*.

Backend (process)
: Process of an *instance* which acts on behalf of a *client session* and handles its requests.

  (Don't confuse this term with the similar terms *Background Worker* or *Background Writer*).

Background worker (process)
: Process within an *instance*, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as *logi-*

	cal replication and *parallel queries*. In addition, *Extensions* can add custom background worker processes. For more information, see Chapter 51.
Background writer (process)	An *auxiliary process* that writes dirty *data pages* from *shared memory* to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes. For more information, see Section 19.4.5.
Base Backup	A binary copy of all *database cluster* files. It is generated by the tool pg_basebackup. In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.
BiHA cluster	A *database cluster* with built-in high availability configured by means of the BiHA solution. See also *leader*, *follower*, and *referee*.
Bloat	Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.
Bootstrap superuser	The first *user* initialized in a *database cluster*. This user owns all system catalog tables in each database. It is also the role from which all granted permissions originate. Because of these things, this role may not be dropped. This role also behaves as a normal *database superuser*.
Buffer Access Strategy	Some operations will access a large number of *pages*. A *Buffer Access Strategy* helps to prevent these operations from evicting too many pages from *shared buffers*. A Buffer Access Strategy sets up references to a limited number of *shared buffers* and reuses them circularly. When the operation requires a new page, a victim buffer is chosen from the buffers in the strategy ring, which may require flushing the page's dirty data and possibly also unflushed *WAL* to permanent storage. Buffer Access Strategies are used for various operations such as sequential scans of large tables, `VACUUM`, `COPY`, `CREATE TABLE AS SELECT`, `ALTER TABLE`, `CREATE DATABASE`, `CREATE INDEX`, and `CLUSTER`.
Cast	A conversion of a *datum* from its current data type to another data type. For more information, see CREATE CAST.
Catalog	The SQL standard uses this term to indicate what is called a *database* in PostgreSQL's terminology. (Don't confuse this term with *system catalog*). For more information, see Section 22.1.
Check constraint	A type of *constraint* defined on a *relation* which restricts the values allowed in one or more *attributes*. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.

For more information, see Section 5.4.

Checkpoint

A point in the *WAL* sequence at which it is guaranteed that the heap and index data files have been updated with all information from *shared memory* modified before that checkpoint; a *checkpoint record* is written and flushed to WAL to mark that point.

A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when predefined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command `CHECKPOINT`.

For more information, see Section 30.5.

Checkpointer (process)

An *auxiliary process* that is responsible for executing *checkpoints*.

Class (archaic)

See Relation.

Client (process)

Any process, possibly remote, that establishes a *session* by *connecting* to an *instance* to interact with a *database*.

Cluster owner

The operating system user that owns the *data directory* and under which the `postgres` process is run. It is required that this user exist prior to creating a new *database cluster*.

On operating systems with a `root` user, said user is not allowed to be the cluster owner.

Column

An *attribute* found in a *table* or *view*.

Commit

The act of finalizing a *transaction* within the *database*, which makes it visible to other transactions and assures its *durability*.

For more information, see COMMIT.

Concurrency

The concept that multiple independent operations happen within the *database* at the same time. In PostgreSQL, concurrency is controlled by the *multiversion concurrency control* mechanism.

Connection

An established line of communication between a client process and a *backend* process, usually over a network, supporting a *session*. This term is sometimes used as a synonym for session.

For more information, see Section 19.3.

Consistency

The property that the data in the *database* is always in compliance with *integrity constraints*. Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically *rolled back*. This is one of the ACID properties.

Constraint

A restriction on the values of data allowed within a *table*, or in attributes of a *domain*.

For more information, see Section 5.4.

Cumulative Statistics System

A system which, if enabled, accumulates statistical information about the *instance*'s activities.

For more information, see Section 28.2.

Data area	See Data directory.
Database	A named collection of *local SQL objects*. For more information, see Section 22.1.
Database cluster	A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a *cluster*. A database cluster is created using the initdb program. In PostgreSQL, the term *cluster* is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command `CLUSTER`.) See also *cluster owner*, the operating-system owner of a cluster, and *bootstrap superuser*, the PostgreSQL owner of a cluster.
Database server	See Instance.
Database superuser	A role having *superuser status* (see Section 21.2). Frequently referred to as *superuser*.
Data directory	The base directory on the file system of a *server* that contains all data files and subdirectories associated with a *database cluster* (with the exception of *tablespaces*, and optionally *WAL*). The environment variable `PGDATA` is commonly used to refer to the data directory. A *cluster*'s storage space comprises the data directory plus any additional tablespaces. For more information, see Section 74.1.
Data page	The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to *shared buffers* where they can be modified, becoming *dirty*. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.
Datum	The internal representation of one value of an SQL data type.
Delete	An SQL command which removes *rows* from a given *table* or *relation*. For more information, see DELETE.
Domain	A user-defined data type that is based on another underlying data type. It acts the same as the underlying type except for possibly restricting the set of allowed values. For more information, see Section 8.18.
Durability	The assurance that once a *transaction* has been *committed*, the changes remain even after a system failure or crash. This is one of the ACID properties.
Extension	A software add-on package that can be installed on an *instance* to get extra features. For more information, see Section 41.17.
File segment	A physical file which stores data for a given *relation*. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.

	For more information, see Section 74.1. (Don't confuse this term with the similar term *WAL segment*).
Follower (node)	A *replica* of the *leader* in the *BiHA cluster*. See also *referee*.
Foreign data wrapper	A means of representing data that is not contained in the local *database* so that it appears as if were in local *table(s)*. With a foreign data wrapper it is possible to define a *foreign server* and *foreign tables*. For more information, see CREATE FOREIGN DATA WRAPPER.
Foreign key	A type of *constraint* defined on one or more *columns* in a *table* which requires the value(s) in those *columns* to identify zero or one *row* in another (or, infrequently, the same) *table*.
Foreign server	A named collection of *foreign tables* which all use the same *foreign data wrapper* and have other configuration values in common. For more information, see CREATE SERVER.
Foreign table (relation)	A *relation* which appears to have *rows* and *columns* similar to a regular *table*, but will forward requests for data through its *foreign data wrapper*, which will return *result sets* structured according to the definition of the *foreign table*. For more information, see CREATE FOREIGN TABLE.
Fork	Each of the separate segmented file sets in which a relation is stored. The *main fork* is where the actual data resides. There also exist two secondary forks for metadata: the *free space map* and the *visibility map*. *Unlogged relations* also have an *init fork*.
Free space map (fork)	A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size. For more information, see Section 74.3.
Function (routine)	A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via `SELECT`. Certain functions can return *sets*; those are called *set-returning functions*. Functions can also be used for *triggers* to invoke. For more information, see CREATE FUNCTION.
GMT	See UTC.
Grant	An SQL command that is used to allow a *user* or *role* to access specific objects within the *database*. For more information, see GRANT.
Heap	Contains the values of *row* attributes (i.e., the data) for a *relation*. The heap is realized within one or more *file segments* in the relation's *main fork*.

Host	A computer that communicates with other computers over a network. This is sometimes used as a synonym for *server*. It is also used to refer to a computer where *client processes* run.
Index (relation)	A *relation* that contains data derived from a *table* or *materialized view*. Its internal structure supports fast retrieval of and access to the original data. For more information, see CREATE INDEX.
Insert	An SQL command used to add new data into a *table*. For more information, see INSERT.
Instance	A group of *backend* and *auxiliary processes* that communicate using a common shared memory area. One *postmaster process* manages the instance; one instance manages exactly one *database cluster* with all its databases. Many instances can run on the same *server* as long as their TCP ports do not conflict. The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, *connections* to *client processes*, privilege verification, crash recovery, replication, etc.
Isolation	The property that the effects of a transaction are not visible to *concurrent transactions* before it commits. This is one of the ACID properties. For more information, see Section 13.2.
Join	An operation and SQL keyword used in *queries* for combining data from multiple *relations*.
Key	A means of identifying a *row* within a *table* or other *relation* by values contained within one or more *attributes* in that relation.
Leader (node)	A *primary server* in the *BiHA cluster*. See also *follower* and *referee*.
Lock	A mechanism that allows a process to limit or prevent simultaneous access to a resource.
Log file	Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc. For more information, see Section 24.3.
Logged	A *table* is considered *logged* if changes to it are sent to the *WAL*. By default, all regular tables are logged. A table can be specified as *unlogged* either at creation time or via the `ALTER TABLE` command.
Logger (process)	An *auxiliary process* which, if enabled, writes information about database events into the current *log file*. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called *syslogger*. For more information, see Section 19.8.
Log record	Archaic term for a *WAL record*.
Log sequence number (LSN)	Byte offset into the *WAL*, increasing monotonically with each new *WAL record*. For more information, see `pg_lsn` and Section 30.7.

LSN	See Log sequence number.
Master (server)	See Primary (server).
Materialized	The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly. This term is used in *materialized view*, to mean that the data derived from the view's query is stored on disk separately from the sources of that data. This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.
Materialized view (relation)	A *relation* that is defined by a `SELECT` statement (just like a *view*), but stores data in the same way that a *table* does. It cannot be modified via `INSERT`, `UPDATE`, `DELETE`, or `MERGE` operations. For more information, see CREATE MATERIALIZED VIEW.
Merge	An SQL command used to conditionally add, modify, or remove *rows* in a given *table*, using data from a source *relation*. For more information, see MERGE.
Multi-version concurrency control (MVCC)	A mechanism designed to allow several *transactions* to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (*versions*) of *tuples* as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.
Null	A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.
Optimizer	See Query planner.
Parallel query	The ability to handle parts of executing a *query* to take advantage of parallel processes on servers with multiple CPUs.
Partition	One of several disjoint (not overlapping) subsets of a larger set. In reference to a *partitioned table*: One of the tables that each contain part of the data of the partitioned table, which is said to be the *parent*. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created. In reference to a *window function* in a *query*, a partition is a user-defined criterion that identifies which neighboring *rows* of the *query's result set* can be considered by the function.
Partitioned table (relation)	A *relation* that is in semantic terms the same as a *table*, but whose storage is distributed across several *partitions*.
Postmaster (process)	The very first process of an *instance*. It starts and manages the *auxiliary processes* and creates *backend processes* on demand. For more information, see Section 18.3.
Primary key	A special case of a *unique constraint* defined on a *table* or other *relation* that also guarantees that all of the *attributes* within the *primary key* do not

	have *null* values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.
Primary (server)	When two or more *databases* are linked via *replication*, the *server* that is considered the authoritative source of information is called the *primary*, also known as a *master*.
Procedure (routine)	A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as `COMMIT` and `ROLLBACK`. They are invoked via the `CALL` command. For more information, see CREATE PROCEDURE.
Query	A request sent by a client to a *backend*, usually to return results or to modify data on the database.
Query planner	The part of PostgreSQL that is devoted to determining (*planning*) the most efficient way to execute *queries*. Also known as *query optimizer*, *optimizer*, or simply *planner*.
Record	See Tuple.
Recycling	See WAL file.
Referee (node)	A node that only participates in voting and does not contain any user data. The referee concept is used in the Built-in High Availability (BiHA) solution and the multimaster extension.
Referential integrity	A means of restricting data in one *relation* by a *foreign key* so that it must have matching data in another *relation*.
Relation	The generic term for all objects in a *database* that have a name and a list of *attributes* defined in a specific order. *Tables*, *sequences*, *views*, *foreign tables*, *materialized views*, composite types, and *indexes* are all relations. More generically, a relation is a set of tuples; for example, the result of a query is also a relation. In PostgreSQL, *Class* is an archaic synonym for *relation*.
Replica (server)	A *database* that is paired with a *primary* database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the *primary* becomes unavailable.
Replication	The act of reproducing data on one *server* onto another server called a *replica*. This can take the form of *physical replication*, where all file changes from one server are copied verbatim, or *logical replication* where a defined subset of data changes are conveyed using a higher-level representation.
Restartpoint	A variant of a *checkpoint* performed on a *replica*. For more information, see Section 30.5.
Result set	A *relation* transmitted from a *backend process* to a *client* upon the completion of an SQL command, usually a `SELECT` but it can be an `INSERT`, `UPDATE`, or `DELETE` command if the `RETURNING` clause is specified. The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a *subquery*.

Revoke

A command to prevent access to a named set of *database* objects for a named list of *roles*.

For more information, see REVOKE.

Role

A collection of access privileges to the *instance*. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple *users* need the same privileges.

For more information, see CREATE ROLE.

Rollback

A command to undo all of the operations performed since the beginning of a *transaction*.

For more information, see ROLLBACK.

Routine

A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be *functions* (including set-returning functions and *trigger functions*), *aggregate functions*, and *procedures*.

Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.

Row

See Tuple.

Savepoint

A special mark in the sequence of steps in a *transaction*. Data modifications after this point in time may be reverted to the time of the savepoint.

For more information, see SAVEPOINT.

Schema

A schema is a namespace for *SQL objects*, which all reside in the same *database*. Each SQL object must reside in exactly one schema.

All system-defined SQL objects reside in schema `pg_catalog`.

More generically, the term *schema* is used to mean all data descriptions (*table* definitions, *constraints*, comments, etc.) for a given *database* or subset thereof.

For more information, see Section 5.9.

Segment

See File segment.

Select

The SQL command used to request data from a *database*. Normally, `SELECT` commands are not expected to modify the *database* in any way, but it is possible that *functions* invoked within the query could have side effects that do modify data.

For more information, see SELECT.

Sequence (relation)

A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate *primary key* values.

Server

A computer on which PostgreSQL *instances* run. The term *server* denotes real hardware, a container, or a *virtual machine*.

This term is sometimes used to refer to an instance or to a host.

Session

A state that allows a client and a backend to interact, communicating over a *connection*.

Shared memory

RAM which is used by the processes common to an *instance*. It mirrors parts of *database* files, provides a transient area for *WAL records*, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.

The largest part of shared memory is known as *shared buffers* and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.

For more information, see Section 19.4.1.

SQL object

Any object that can be created with a `CREATE` command. Most objects are specific to one database, and are commonly known as *local objects*.

Most local objects reside in a specific *schema* in their containing database, such as *relations* (all types), *routines* (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.

There also exist local objects that do not reside in schemas; some examples are *extensions*, *data type casts*, and *foreign data wrappers*. The names of such objects of the same type are enforced to be unique within the database.

Other object types, such as *roles*, *tablespaces*, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called *global objects*. The names of such objects are enforced to be unique within the whole database cluster.

For more information, see Section 22.1.

SQL standard

A series of documents that define the SQL language.

Standby (server)

See Replica (server).

Startup process

An *auxiliary process* that replays WAL during crash recovery and in a *physical replica*.

(The name is historical: the startup process was named before replication was implemented; the name refers to its task as it relates to the server startup following a crash.)

Superuser

As used in this documentation, it is a synonym for *database superuser*.

System catalog

A collection of *tables* which describe the structure of all *SQL objects* of the instance. The system catalog resides in the schema `pg_catalog`. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier *views*, also in schema `pg_catalog`, offer more convenient access to some of that information, while additional tables and views exist in schema `information_schema` (see Chapter 40) that expose some of the same and additional information as mandated by the *SQL standard*.

For more information, see Section 5.9.

Table

A collection of *tuples* having a common data structure (the same number of *attributes*, in the same order, having the same name and type per position). A table is the most common form of *relation* in PostgreSQL.

	For more information, see CREATE TABLE.
Tablespace	A named location on the server file system. All *SQL objects* which require storage beyond their definition in the *system catalog* must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called `pg_default`. For more information, see Section 22.6.
Temporary table	*Tables* that exist either for the lifetime of a *session* or a *transaction*, as specified at the time of creation. The data in them is not visible to other sessions, and is not *logged*. Temporary tables are often used to store intermediate data for a multi-step operation. For more information, see CREATE TABLE.
TOAST	A mechanism by which large attributes of table rows are split and stored in a secondary table, called the *TOAST table*. Each relation with large attributes has its own TOAST table. For more information, see Section 74.2.
Transaction	A combination of commands that must act as a single *atomic* command: they all succeed or all fail as a single unit, and their effects are not visible to other *sessions* until the transaction is complete, and possibly even later, depending on the isolation level. For more information, see Section 13.2.
Transaction ID	The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as *xid*. For more information, see Section 8.19.
Transactions per second (TPS)	Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.
Trigger	A *function* which can be defined to execute whenever a certain operation (`INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`) is applied to a *relation*. A trigger executes within the same *transaction* as the statement which invoked it, and if the function fails, then the invoking statement also fails. For more information, see CREATE TRIGGER.
Tuple	A collection of *attributes* in a fixed order. That order may be defined by the *table* (or other *relation*) where the tuple is contained, in which case the tuple is often called a *row*. It may also be defined by the structure of a result set, in which case it is sometimes called a *record*.
Unique constraint	A type of *constraint* defined on a *relation* which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those. Because *null values* are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.
Unlogged	The property of certain *relations* that the changes to them are not reflected in the *WAL*. This disables replication and crash recovery for these relations.

The primary use of unlogged tables is for storing transient work data that must be shared across processes.

Temporary tables are always unlogged.

Update

An SQL command used to modify *rows* that may already exist in a specified *table*. It cannot create or remove rows.

For more information, see UPDATE.

User

A *role* that has the *login privilege* (see Section 21.2).

User mapping

The translation of login credentials in the local *database* to credentials in a remote data system defined by a *foreign data wrapper*.

For more information, see CREATE USER MAPPING.

UTC

Universal Coordinated Time, the primary global time reference, approximately the time prevailing at the zero meridian of longitude. Often but inaccurately referred to as GMT (Greenwich Mean Time).

Vacuum

The process of removing outdated *tuple versions* from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of *MVCC*. This can be initiated through the use of the `VACUUM` command, but can also be handled automatically via *autovacuum* processes.

For more information, see Section 24.1 .

View

A *relation* that is defined by a `SELECT` statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view.

For more information, see CREATE VIEW.

Visibility map (fork)

A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (`all-visible`) indicates that all tuples in the page are visible to all transactions. The second one (`all-frozen`) indicates that all tuples in the page are marked frozen.

WAL

See Write-ahead log.

WAL archiver (process)

An *auxiliary process* which, if enabled, saves copies of *WAL files* for the purpose of creating backups or keeping *replicas* current.

For more information, see Section 25.3.

WAL file

Also known as *WAL segment* or *WAL segment file*. Each of the sequentially-numbered files that provide storage space for *WAL*. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.

Each WAL file can be released after a *checkpoint* writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called *recycling*.

For more information, see Section 30.7.

WAL record

A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (*replayed*) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.

For more information, see Section 30.7.

WAL receiver (process)

An *auxiliary process* that runs on a *replica* to receive WAL from the *primary server* for replay by the *startup process*.

For more information, see Section 26.2.

WAL segment

See WAL file.

WAL sender (process)

A special *backend process* that streams WAL over a network. The receiving end can be a *WAL receiver* in a *replica*, pg_receivewal, or any other client program that speaks the replication protocol.

WAL writer (process)

An *auxiliary process* that writes *WAL records* from *shared memory* to *WAL files*.

For more information, see Section 19.5.

Window function (routine)

A type of *function* used in a *query* that applies to a *partition* of the query's *result set*; the function's result is based on values found in *rows* of the same partition or frame.

All *aggregate functions* can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as *analytic functions*.

For more information, see Section 3.5.

Write-ahead log

The journal that keeps track of the changes in the *database cluster* as user- and system-invoked operations take place. It comprises many individual *WAL records* written sequentially to *WAL files*.

Appendix Q. Color Support

Most programs in the Postgres Pro package can produce colorized console output. This appendix describes how that is configured.

Q.1. When Color is Used

To use colorized output, set the environment variable `PG_COLOR`as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

Q.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS`(note plural). The value is a colon-separated list of *`key=value`* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`note`

used to highlight the text “detail” and “hint” in such messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:note=01;36:locus=01` (`01;31` = bold red, `01;35` = bold magenta, `01;36` = bold cyan, `01` = bold default color).

> **Tip**
>
> This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

Appendix R. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

R.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See the release notes for PostgreSQL 12 for details on this change.

On Postgres Pro 12 and above, archive recovery, streaming replication, and PITR are configured using normal server configuration parameters. These are set in `postgresql.conf` or via ALTER SYSTEM like any other parameter.

The server will not start if a `recovery.conf` exists.

Postgres Pro 15 and below had a setting `promote_trigger_file`, or `trigger_file` before 12. Use `pg_ctl promote` or call `pg_promote()` to promote a standby instead.

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See Standby Server Operation for details.

R.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See Section 21.5 for current documentation regarding Predefined Roles, and the release notes for PostgreSQL 14 for details on this change.

R.3. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see pg_waldump for documentation of `pg_waldump` and see the release notes for PostgreSQL 10 for details on this change.

R.4. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see pg_resetwal for documentation of `pg_resetwal` and see the release notes for PostgreSQL 10 for details on this change.

R.5. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see pg_receivewal for documentation of `pg_receivewal` and see the release notes for PostgreSQL 10 for details on this change.

Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department *web site*.
