## 2 Module Documentation

### 2.1 Adaptors for pointers to functions

Collaboration diagram for Adaptors for pointers to functions:

## Classes

- class `std::pointer_to_binary_function< _Arg1, _Arg2, _Result >`
- class `std::pointer_to_unary_function< _Arg, _Result >`

## Functions

- `template<typename _Arg, typename _Result >`  
`pointer_to_unary_function< _Arg, _Result > std::ptr_fun ( _Result(*)(_Arg))`
- `template<typename _Arg1, typename _Arg2, typename _Result >`  
`pointer_to_binary_function< _Arg1, _Arg2, _Result > std::ptr_fun ( _Result(*)(_Arg1, _Arg2))`

### 2.1.1 Detailed Description

The advantage of function objects over pointers to functions is that the objects in the standard library declare nested typedefs describing their argument and result types with uniform names (e.g., `result_type` from the base classes `unary_function` and `binary_function`). Sometimes those typedefs are required, not just optional.

Adaptors are provided to turn pointers to unary (single-argument) and binary (double-argument) functions into function objects. The long-winded functor `pointer_to_unary_function` is constructed with a function pointer `f`, and its `operator()` called with argument `x` returns `f(x)`. The functor `pointer_to_binary_function` does the same thing, but with a double-argument `f` and `operator()`.

The function `ptr_fun` takes a pointer-to-function `f` and constructs an instance of the appropriate functor.

### 2.1.2 Function Documentation

**2.1.2.1** `template<typename _Arg, typename _Result > pointer_to_unary_function< _Arg, _Result > std::ptr_fun ( _Result(*)(_Arg) __x ) [inline]`

One of the [adaptors for function pointers](#).

**2.1.2.2** `template<typename _Arg1, typename _Arg2, typename _Result > pointer_to_binary_function< _Arg1, _Arg2, _Result > std::ptr_fun ( _Result(*)(_Arg1, _Arg2) __x ) [inline]`

One of the [adaptors for function pointers](#).

- class `std::mem_fun_t<_Ret, _Tp>`

### Functions

- `template<typename _Ret, typename _Tp>`  
`mem_fun_ref_t<_Ret, _Tp> std::mem_fun_ref (_Ret(_Tp::*__f)())`
- `template<typename _Ret, typename _Tp, typename _Arg>`  
`mem_fun1_ref_t<_Ret, _Tp, _Arg> std::mem_fun_ref (_Ret(_Tp::*__f)(_Arg))`

#### 2.2.1 Detailed Description

There are a total of  $8 = 2^3$  function objects in this family. (1) Member functions taking no arguments vs member functions taking one argument. (2) Call through pointer vs call through reference. (3) Const vs non-const member function.

All of this complexity is in the function objects themselves. You can ignore it by using the helper function `mem_fun` and `mem_fun_ref`, which create whichever type of adaptor is appropriate.

- struct `std::modulus<_Tp>`
- struct `std::multiplies<_Tp>`
- struct `std::negate<_Tp>`
- struct `std::plus<_Tp>`

### 2.5.1 Detailed Description

Because basic math often needs to be done during an algorithm, the library provides functors for those operations. See the documentation for [the base classes](#) for examples of their use.

## 2.6 Associative

Collaboration diagram for Associative:

### Classes

- class `std::map<_Key, _Tp, _Compare, _Alloc>`

### 2.6.1 Detailed Description

Associative containers allow fast retrieval of data based on keys.

Each container type is parameterized on a `Key` type, and an ordering relation used to sort the elements of the container.

All associative containers must meet certain requirements, summarized in [tables](#).

### 2.14.1 Detailed Description

These algorithms are variations of a classic binary search, and all assume that the sequence being searched is already sorted.

The number of comparisons will be logarithmic (and as few as possible). The number of steps through the sequence will be logarithmic for random-access iterators (e.g., pointers), and linear otherwise.

The LWG has passed Defect Report 270, which notes: *The proposed resolution reinterprets binary search. Instead of thinking about searching for a value in a sorted range, we view that as an important special case of a more general algorithm: searching for the partition point in a partitioned range. We also add a guarantee that the old wording did not: we ensure that the upper bound is no earlier than the lower bound, that the pair returned by equal\_range is a valid range, and that the first part of that pair is the lower bound.*

The actual effect of the first sentence is that a comparison functor passed by the user doesn't necessarily need to induce a strict weak ordering relation. Rather, it partitions the range.

- `template<typename _Operation, typename _Tp>`  
`binder2nd<_Operation> std::bind2nd(const _Operation &__fn, const _Tp &__x)`

#### 2.15.1 Detailed Description

Binders turn functions/functors with two arguments into functors with a single argument, storing an argument to be applied later. For example, a variable `B` of type `binder1st` is constructed from a functor `f` and an argument `x`. Later, `B's operator()` is called with a single argument `y`. The return value is the value of `f(x, y)`. `B` can be *called* with various arguments (`y1, y2, ...`) and will in turn call `f(x, y1), f(x, y2), ...`

The function `bind1st` is provided to save some typing. It takes the function and an argument as parameters, and returns an instance of `binder1st`.

The type `binder2nd` and its creator function `bind2nd` do the same thing, but the stored argument is passed as the second parameter instead of the first, e.g., `bind2nd(std::minus<float>(), 1.3)` will create a functor whose `operator()` accepts a floating-point number, subtracts 1.3 from it, and returns the result. (If `bind1st` had been used, the functor would perform `1.3 - x` instead.

Creator-wrapper functions like `bind1st` are intended to be used in calling algorithms. Their return values will be temporary objects. (The goal is to not require you to type names like `std::binder1st<std::plus<int>>` for declaring a variable to hold the return value from `bind1st(std::plus<int>(), 5)`.

These become more useful when combined with the composition functions.

These functions are deprecated in C++11 and can be replaced by `std::bind` (or `std::tr1::bind`) which is more powerful and flexible, supporting functions with any number of arguments. Uses of `bind1st` can be replaced by `std::bind(f, x, std::placeholders::_1)` and `bind2nd` by `std::bind(f, std::placeholders::_1, x)`.

## 2.21 Containers

Collaboration diagram for Containers:

### Modules

- [Associative](#)
- [Sequences](#)
- [Unordered Associative](#)

#### 2.21.1 Detailed Description

Containers are collections of objects.

A container may hold any type which meets certain requirements, but the type of contained object is chosen at compile time, and all objects in a given container must be of the same type. (Polymorphism is possible by declaring a container of pointers to a base class and then populating it with pointers to instances of derived classes. Variant value types such as the `any` class from `Boost` can also be used.

All contained types must be `Assignable` and `CopyConstructible`. Specific containers may place additional requirements on the types of their contained objects.

Containers manage memory allocation and deallocation themselves when storing your objects. The objects are destroyed when the container is itself destroyed. Note that if you are storing pointers in a container, `delete` is *not* automatically called on the pointers before destroying them.

All containers must meet certain requirements, summarized in `tables`.

The standard containers are further refined into [Sequences](#) and [Associative Containers](#). [Unordered Associative Containers](#).

### 2.27.1 Detailed Description

Function objects, or *functors*, are objects with an `operator()` defined and accessible. They can be passed as arguments to algorithm templates and used in place of a function pointer. Not only is the resulting expressiveness of the library increased, but the generated code can be more efficient than what you might write by hand. When we refer to *functors*, then, generally we include function pointers in the description as well.

Often, functors are only created as temporaries passed to algorithm calls, rather than being created as named variables.

Two examples taken from the standard itself follow. To perform a by-element addition of two vectors `a` and `b` containing `double`, and put the result in `a`, use

```
transform (a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
```

To negate every element in `a`, use

```
transform(a.begin(), a.end(), a.begin(), negate<double>());
```

The addition and negation functions will be inlined directly.

The standard functors are derived from structs named `unary_function` and `binary_function`. These two classes contain nothing but typedefs, to aid in generic (template) programming. If you write your own functors, you might consider doing the same.

These are empty types, used to distinguish different iterators. The distinction is not made by what they contain, but simply by what they are. Different underlying algorithms can then be used based on the different operations supported by different iterator types.

### 2.34.1 Detailed Description

Abstractions for uniform iterating through various underlying types.

### 2.34.2 Function Documentation

2.34.2.1 `template<typename _Iter > iterator_traits<_Iter>::iterator_category std::__iterator_category ( const _Iter & )`  
`[inline]`

This function is not a part of the C++ standard but is syntactic sugar for internal library use only.

Definition at line 201 of file `stl_iterator_base_types.h`.

Referenced by `std::__find_if_not()`, `__gnu_debug::__valid_range_aux()`, `std::advance()`, `std::copy_n()`, `std::distance()`, `std::find()`, `std::find_end()`, `std::find_if()`, `std::partition()`, `std::reverse()`, `std::search_n()`, `std::uninitialized_copy_n()`, and `std::unique_copy()`.

**2.34.2.2** `template<typename _Container > back_insert_iterator<_Container> std::back_inserter ( _Container & __x )`  
`[inline]`

#### Parameters

<code>__x</code>	A container of arbitrary type.
------------------	--------------------------------

#### Returns

An instance of `back_insert_iterator` working on `__x`.

This wrapper function helps in creating `back_insert_iterator` instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

Definition at line 479 of file `stl_iterator.h`.

Referenced by `std::match_results<_FwdIterT, _Alloc >::format()`, and `std::regex_replace()`.

**2.34.2.3** `template<typename _Container > front_insert_iterator<_Container> std::front_inserter ( _Container & __x )`  
`[inline]`

#### Parameters

<code>__x</code>	A container of arbitrary type.
------------------	--------------------------------

#### Returns

An instance of `front_insert_iterator` working on `x`.

This wrapper function helps in creating `front_insert_iterator` instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

#### Returns

An instance of `insert_iterator` working on `__x`.

This wrapper function helps in creating `insert_iterator` instances. 2.34.2.7 `template<typename _Iterator > bool std::operator== ( const reverse_iterator< _Iterator > & __x, const reverse_iterator< _Iterator > & __y ) [inline]`

#### Parameters

<code>__x</code>	A reverse_iterator.
<code>__y</code>	A reverse_iterator.

#### Returns

A simple bool.

Reverse iterators forward many operations to their underlying base() iterators. Others are implemented in terms of one another.

## 2.37.1 Detailed Description

## 2.37.2 Function Documentation

2.37.2.1 `template<typename _II, typename _OI> _OI std::copy ( _II __first, _II __last, _OI __result ) [inline]`

Copies the range [first,last) into result.

## Parameters

<code>__first</code>	An input iterator.
<code>__last</code>	An input iterator.
<code>__result</code>	An output iterator.

## Returns

`result + (first - last)`

This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling). Result may not be contained within [first,last); the `copy_backward` function should be used instead.

Note that the end of the output range is permitted to be contained within [first,last).

Definition at line 450 of file `stl_algobase.h`.

2.37.2.2 `template<typename _BI1, typename _BI2> _BI2 std::copy_backward ( _BI1 __first, _BI1 __last, _BI2 __result ) [inline]`

Copies the range [first,last) into result.

## Parameters

<code>__first</code>	A bidirectional iterator.
<code>__last</code>	A bidirectional iterator.
<code>__result</code>	A bidirectional iterator.

## Returns

`result - (first - last)`

The function has the same effect as `copy`, but starts at the end of the range and works its way to the start, returning the start of the result. This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

Result may not be in the range (first,last]. Use `copy` instead. Note that the start of the output range may overlap [first,last).

Definition at line 619 of file `stl_algobase.h`.

2.37.2.3 `template<typename _InputIterator, typename _OutputIterator, typename _Predicate> _OutputIterator std::copy_if ( _InputIterator __first, _InputIterator __last, _OutputIterator __result, _Predicate __pred )`

Copy the elements of a sequence for which a predicate is true.

**Parameters**

<code>__first</code>	An input iterator.
<code>__last</code>	An input iterator.
<code>__result</code>	An output iterator.
<code>__pred</code>	A predicate.

**Returns**

An iterator designating the end of the resulting sequence.

Copies each element in the range `[__first,__last)` for which `__pred` returns true to the range beginning at `__result`. `copy_if()` is stable, so the relative order of elements that are copied is unchanged.

Definition at line 950 of file `stl_algo.h`.

```
2.37.2.4 template<typename _InputIterator, typename _Size, typename _OutputIterator > _OutputIterator std::copy_n (
    _InputIterator __first, _Size __n, _OutputIterator __result ) [inline]
```

Copies the range `[first,first+n)` into `[result,result+n)`.

**Parameters**

<code>__first</code>	An input iterator.
<code>__n</code>	The number of elements to copy.
<code>__result</code>	An output iterator.

**Returns**

`result+n`.

This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

Definition at line 1013 of file `stl_algo.h`.

```
2.37.2.5 template<typename _ForwardIterator, typename _Tp > void std::fill ( _ForwardIterator __first, _ForwardIterator __last,
    const _Tp & __value ) [inline]
```

Fills the range `[first,last)` with copies of `value`.

**Parameters**

<code>__first</code>	A forward iterator.
<code>__last</code>	A forward iterator.
<code>__value</code>	A reference-to-const of arbitrary type.

**Returns**

Nothing.

This function fills a range with copies of the same value. For char types filling contiguous areas of memory, this becomes an inline call to `memset` or `wmemset`.

Definition at line 721 of file `stl_algobase.h`.

```
2.37.2.6  template<typename _OI, typename _Size, typename _Tp > _OI std::fill_n ( _OI __first, _Size __n, const _Tp & __value )  
          [inline]
```

Fills the range [first,first+n) with copies of value.

**Parameters**

<code>__first</code>	An output iterator.
<code>__n</code>	The count of copies to perform.
<code>__value</code>	A reference-to-const of arbitrary type.

**Returns**

The iterator at `first+n`.

This function fills a range with copies of the same value. For char types filling contiguous areas of memory, this becomes an inline call to `memset` or `@ wmemset`.

**Returns**

The end of the sequence, `__first+__n`

Performs the assignment `*i = __gen()` for each `i` in the range `[__first, __first+__n)`.

Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

**Returns**

An iterator `middle` such that `__pred(i)` is true for each iterator `i` in the range `[__first,middle)` and false for each `i` in the range `[middle,__last)`.

<code>__middle</code>	A forward iterator.
<code>__last</code>	A forward iterator.

<code>__unary_op</code>	A unary operator.

**Returns**

## 2.38 Negators

Collaboration diagram for Negators:

### Classes

- class `std::binary_negate<_Predicate>`
- class `std::unary_negate<_Predicate>`

### Functions

- template<typename \_Predicate>  
`unary_negate<_Predicate>` `std::not1` (const \_Predicate &\_\_pred)
- template<typename \_Predicate>  
`binary_negate<_Predicate>` `std::not2` (const \_Predicate &\_\_pred)

#### 2.38.1 Detailed Description

The functions `not1` and `not2` each take a predicate functor and return an instance of `unary_negate` or `binary_negate`, respectively. These classes are functors whose `operator()` performs the stored predicate function and then returns the negation of the result.

For example, given a vector of integers and a trivial predicate,

```

struct IntGreaterThanThree
: public std::unary_function<int, bool>
{
    bool operator() (int x) { return x > 3; }
};

std::find_if (v.begin(), v.end(), not1(IntGreaterThanThree()));
  
```

The call to `find_if` will locate the first index (*i*) of *v* for which `!(v[i] > 3)` is true.

The `not1/unary_negate` combination works on predicates taking a single argument. The `not2/binary_negate` combination works on predicates which take two arguments.

Searches the range `[__first1, __last1)` for a sub-sequence that compares equal value-by-value with the sequence given by `[__first2, __last2)` and returns an iterator to the `__first` element of the sub-sequence, or `__last1` if the sub-sequence is not found. The sub-sequence will be the last such subsequence contained in `[__first, __last1)`.

Because the sub-sequence must lie completely within the range  $[\_first1, \_last1)$  it must start at a position less than  $\_last1 - (\_last2 - \_first2)$  where  $\_last2 - \_first2$  is the length of the sub-sequence. This means that the returned iterator  $i$  will be in the range  $[\_first1, \_last1 - (\_last2 - \_first2))$

### 2.47.1 Detailed Description

These classes define objects which provide random or pseudorandom numbers, either from a discrete or a continuous interval. The random number generator supplied as a part of this library are all uniform random number generators which provide a sequence of random number uniformly distributed over their range.

A number generator is a function object with an `operator()` that takes zero arguments and returns a number.

A compliant random number generator must satisfy the following requirements.

To be documented.

Table 1: Random Number Generator Requirements

### 2.49.1 Detailed Description

A facility for performing regular expression pattern matching.

### 2.49.2 Typedef Documentation

#### 2.49.2.1 `typedef regex_token_iterator<const char*> std::cregex_token_iterator`

Token iterator for C-style NULL-terminated strings.

Definition at line 2469 of file `regex.h`.

#### 2.49.2.2 `typedef sub_match<const char*> std::csub_match`

Standard regex submatch over a C-style null-terminated string.

Definition at line 834 of file `regex.h`.

#### 2.49.2.3 `typedef std::bitset<_S_match_flag_last> std::regex_constants::match_flag_type`

This is a bitmask type indicating regex matching rules.

## 2.49.5 Variable Documentation

### 2.49.5.1 `constexpr syntax_option_type std::regex_constants::awk`

Specifies that the grammar recognized by the regular expression engine is that used by POSIX utility `awk` in IEEE Std 1003.1-2001. This option is identical to `syntax_option_type` extended, except that C-style escape sequences are supported. These sequences are: `\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, `\'`, and `\ddd` (where `ddd` is one, two, or three octal digits).

Definition at line 144 of file `regex_constants.h`.

### 2.49.5.2 `constexpr syntax_option_type std::regex_constants::basic`

Specifies that the grammar recognized by the regular expression engine is that used by POSIX basic regular expressions in IEEE Std 1003.1-2001, Portable Operating System Interface (POSIX), Base Definitions and Headers, Section 9, Regular Expressions [IEEE, Information Technology – Portable Operating System Interface (POSIX), IEEE Standard 1003.1-2001].

Definition at line 126 of file `regex_constants.h`.

### 2.49.5.3 `constexpr syntax_option_type std::regex_constants::collate`

Specifies that character ranges of the form `[a-b]` should be locale sensitive.

Definition at line 107 of file `regex_constants.h`.

### 2.49.5.4 `constexpr syntax_option_type std::regex_constants::ECMAScript`

Specifies that the grammar recognized by the regular expression engine is that used by ECMAScript in ECMA-262 [Ecma International, ECMAScript Language Specification, Standard Ecma-262, third edition, 1999], as modified in section [28.13]. This grammar is similar to that defined in the PERL scripting language but extended with elements found in the POSIX regular expression grammar.

Definition at line 117 of file `regex_constants.h`.

### 2.49.5.5 `constexpr syntax_option_type std::regex_constants::egrep`

Specifies that the grammar recognized by the regular expression engine is that used by POSIX utility `grep` when given the `-E` option in IEEE Std 1003.1-2001. This option is identical to `syntax_option_type` extended, except that newlines are treated as whitespace.

Definition at line 160 of file `regex_constants.h`.

### 2.49.5.6 `constexpr syntax_option_type std::regex_constants::extended`

Specifies that the grammar recognized by the regular expression engine is that used by POSIX extended regular expressions in IEEE Std 1003.1-2001, Portable Operating System Interface (POSIX), Base Definitions and Headers, Section 9, Regular Expressions.

Definition at line 134 of file `regex_constants.h`.

#### 2.49.5.7 `constexpr match_flag_type std::regex_constants::format_default`

When a regular expression match is to be replaced by a new string, the new string is constructed using the rules used by the ECMAScript `replace` function in ECMA- 262 [Ecma International, ECMAScript Language Specification, Standard Ecma-262, third edition, 1999], part 15.5.4.11 `String.prototype.replace`. In addition, during search and replace operations all non-overlapping occurrences of the regular expression are located and replaced, and sections of the input that did not match the expression are copied unchanged to the output string.

Format strings (from ECMA-262 [15.5.4.11]):

- `$$` The dollar-sign itself (`$`)
- `$&` The matched substring.
- `$'` The portion of *string* that precedes the matched substring. This would be `match_results::prefix()`.
- `$'` The portion of *string* that follows the matched substring. This would be `match_results::suffix()`.
- `$n` The *n*th capture, where *n* is in `[1,9]` and `$n` is not followed by a decimal digit. If `n <= match_results::size()` and the *n*th capture is undefined, use the empty string instead. If `n > match_results::size()`, the result is implementation-defined.
- `$nn` The *nn*th capture, where *nn* is a two-digit decimal number on `[01, 99]`. If `nn <= match_results::size()` and the *nn*th capture is undefined, use the empty string instead. If `nn > match_results::size()`, the result is implementation-defined.

Definition at line 280 of file `regex_constants.h`.

#### 2.49.5.8 `constexpr match_flag_type std::regex_constants::format_first_only`

When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.

Definition at line 301 of file `regex_constants.h`.

#### 2.49.5.9 `constexpr match_flag_type std::regex_constants::format_no_copy`

During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.

Definition at line 295 of file `regex_constants.h`.

#### 2.49.5.10 `constexpr match_flag_type std::regex_constants::format_sed`

When a regular expression match is to be replaced by a new string, the new string is constructed using the rules used by the POSIX `sed` utility in IEEE Std 1003.1- 2001 [IEEE, Information Technology – Portable Operating System Interface (POSIX), IEEE Standard 1003.1-2001].

Definition at line 288 of file `regex_constants.h`.

#### 2.49.5.11 `constexpr syntax_option_type std::regex_constants::grep`

Specifies that the grammar recognized by the regular expression engine is that used by POSIX utility `grep` in IEEE Std 1003.1-2001. This option is identical to `syntax_option_type basic`, except that newlines are treated as whitespace.

Definition at line 152 of file `regex_constants.h`.

**2.49.5.19 constexpr match\_flag\_type std::regex\_constants::match\_not\_eow**

The expression \b should not be matched against the sub-sequence [last,last).

Definition at line 229 of file `regex_constants.h`.

**2.49.5.20 constexpr match\_flag\_type std::regex\_constants::match\_not\_null**

The expression does not match an empty sequence.

**2.49.5.21 constexpr match\_flag\_type std::regex\_constants::match\_prev\_avail**

—first is a valid iterator position. When this flag is set then the flags `match_not_bol` and `match_not_bow` are ignored by the regular expression algorithms 28.11 and iterators 28.12.

#### 2.49.5.22 `constexpr syntax_option_type std::regex_constants::nosubs`

## 2.50 SGI

Collaboration diagram for SGI:

Because libstdc++ based its implementation of the STL subsections of the library on the SGI 3.3 implementation, we inherited their extensions as well.

They are additionally documented in the [online documentation](#), a copy of which is also shipped with the library source code (in `.../docs/html/documentation.html`). You can also read the documentation [on SGI's site](#), which is still running even though the code is not maintained.

**NB** that the following notes are pulled from various comments all over the place, so they may seem stilted.

## 2.51 Sequences

- class `std::queue<_Tp, _Sequence>`
- class `std::stack<_Tp, _Sequence>`
- class `std::vector<_Tp, _Alloc>`
- class `std::vector<bool, _Alloc>`

### 2.51.1 Detailed Description

Sequences arrange a collection of objects into a strictly linear order.

The differences between sequences are usually due to one or both of the following:

- memory management
- algorithmic complexity

As an example of the first case, `vector` is required to use a contiguous memory layout, while other sequences such as `deque` are not.

The prime reason for choosing one sequence over another should be based on the second category of differences, algorithmic complexity. For example, if you need to perform many inserts and removals from the middle of a sequence, `list` would be ideal. But if you need to perform constant-time access to random elements of the sequence, then `list` should not be used.

All sequences must meet certain requirements, summarized in [tables](#).

### 2.52.1 Detailed Description

These algorithms are common set operations performed on sequences that are already sorted. The number of comparisons will be linear.

## 2.52.2 Function Documentation

2.52.2.1 `template<typename _InputIterator1, typename _InputIterator2 > bool std::includes ( _InputIterator1 __first1, _InputIterator1 __last1, _InputIterator2 __first2, _InputIterator2 __last2 )`

Determines whether all elements of a sequence exists in a range.

**Parameters**

<code>__first1</code>	Start of search range.
<code>__last1</code>	End of search range.
<code>__first2</code>	Start of sequence
<code>__last2</code>	End of sequence.

**Returns**

True if each element in `[__first2,__last2)` is contained in order within `[__first1,__last1)`. False otherwise.

This operation expects both `[__first1,__last1)` and `[__first2,__last2)` to be sorted. Searches for the presence of each element in `[__first2,__last2)` within `[__first1,__last1)`. The iterators over each range only move forward, so this is a linear algorithm. If an element in `[__first2,__last2)` is not found before the search iterator reaches `__last2`, false is returned.

Definition at line 3549 of file `stl_algo.h`.

**2.52.2.2** `template<typename _InputIterator1, typename _InputIterator2, typename _Compare > bool std::includes ( _InputIterator1 __first1, _InputIterator1 __last1, _InputIterator2 __first2, _InputIterator2 __last2, _Compare __comp )`

Determines whether all elements of a sequence exists in a range using comparison.

**Parameters**

<code>__first1</code>	Start of search range.
<code>__last1</code>	End of search range.
<code>__first2</code>	Start of sequence
<code>__last2</code>	End of sequence.
<code>__comp</code>	Comparison function to use.

**Returns**

True if each element in `[__first2,__last2)` is contained in order within `[__first1,__last1)` according to `comp`. False otherwise.

This operation expects both `[__first1,__last1)` and `[__first2,__last2)` to be sorted. Searches for the presence of each element in `[__first2,__last2)` within `[__first1,__last1)`, using `comp` to decide. The iterators over each range only move forward, so this is a linear algorithm. If an element in `[__first2,__last2)` is not found before the search iterator reaches `__last2`, false is returned.

Definition at line 3600 of file `stl_algo.h`.

**2.52.2.3** `template<typename _InputIterator1, typename _InputIterator2, typename _OutputIterator > _OutputIterator std::set_difference ( _InputIterator1 __first1, _InputIterator1 __last1, _InputIterator2 __first2, _InputIterator2 __last2, _OutputIterator __result )`

Return the difference of two sorted ranges.

**Parameters**

<code>__first1</code>	Start of first range.
<code>__last1</code>	End of first range.
<code>__first2</code>	Start of second range.

<code>__last2</code>	End of second range.
----------------------	----------------------

**Returns**

End of the output range.

This operation iterates over both ranges, copying elements present in the first range but not the second in order to the output range. Iterators increment for each range. When the current element of the first range is less than the second, that element is copied and the iterator advances. If the current element of the second range is less, the iterator advances, but no element is copied. If an element is contained in both ranges, no elements are copied and both ranges advance. The output range may not overlap either input range.

**Parameters**

<code>__first1</code>	Start of first range.
<code>__last1</code>	End of first range.
<code>__first2</code>	Start of second range.
<code>__last2</code>	End of second range.

**Returns**

End of the output range.

This operation iterates over both ranges, copying elements present in both ranges in order to the output range. Iterators increment for each range. ### 2.53.1 Detailed Description

### 2.53.2 Function Documentation

**2.53.2.1** `template<typename _BidirectionalIterator > void std::inplace_merge ( _BidirectionalIterator __first, _BidirectionalIterator __middle, _BidirectionalIterator __last )`

Merges two sorted ranges in place.

#### Parameters

<code>__first</code>	An iterator.
<code>__middle</code>	Another iterator.
<code>__last</code>	Another iterator.

#### Returns

Nothing.

Merges two sorted and consecutive ranges, [`__first`,`__middle`) and [`__middle`,`__last`), and puts the result in [`__first`,`__last`). The output will be sorted. The sort is *stable*, that is, for equivalent elements in the two ranges, elements from the first range will always come before elements from the second.

If enough additional memory is available, this takes (`__last`-`__first`)-1 comparisons. Otherwise an NlogN algorithm is used, where N is `distance(__first,__last)`.

Definition at line 3154 of file `stl_algo.h`.

**2.53.2.2** `template<typename _BidirectionalIterator, typename _Compare > void std::inplace_merge ( _BidirectionalIterator __first, _BidirectionalIterator __middle, _BidirectionalIterator __last, _Compare __comp )`

Merges two sorted ranges in place.

#### Parameters

<code>__first</code>	An iterator.
<code>__middle</code>	Another iterator.
<code>__last</code>	Another iterator.
<code>__comp</code>	A functor to use for comparisons.

#### Returns

Nothing.

Merges two sorted and consecutive ranges, [`__first`,`__middle`) and [`__middle`,`__last`), and puts the result in [`__first`,`__last`). The output will be sorted. The sort is *stable*, that is, for equivalent elements in the two ranges, elements from the first range will always come before elements from the second.

If enough additional memory is available, this takes (`__last`-`__first`)-1 comparisons. Otherwise an NlogN algorithm is used, where N is `distance(__first,__last)`.

The comparison function should have the same effects on ordering as the function used for the initial sort.

Collaboration diagram for Unordered Associative:

### Modules

### Classes

- class `std::unordered_map<_Key, _Tp, _Hash, _Pred, _Alloc>`

- class `std::unordered_multiset<_Value, _Hash, _Pred, _Alloc>`
- class `std::unordered_set<_Value, _Hash, _Pred, _Alloc>`

### 2.58.1 Detailed Description

Unordered associative containers allow fast retrieval of data based on keys.

Each container type is parameterized on a `Key` type, a `Hash` type providing a hashing functor, and an ordering relation used to sort the elements of the container.

All unordered associative containers must meet certain requirements, summarized in [tables](#).

GNU extensions for public use.

### 3.1.2 Function Documentation

**3.1.2.1** `template<typename _ToType , typename _FromType > _ToType __gnu_cxx::__static_pointer_cast ( const _FromType & __arg ) [inline]`

Casting operations for cases where `_FromType` is not a standard pointer. `_ToType` can be a standard or non-standard pointer. Given that `_FromType` is not a pointer, it must have a `get()` method that returns the standard pointer equivalent of the address it points to, and must have an `element_type` typedef which names the type it points to.

Definition at line 68 of file `cast.h`.

3.1.2.2 `template<typename _ToType, typename _FromType> _ToType __gnu_cxx::__static_pointer_cast( _FromType * __arg )`

3.4.3.14 `template<typename _Integral> bool __gnu_debug::__valid_range_aux ( const _Integral &, const _Integral &, std::__true_type ) [inline]`

We say that integral types for a valid range, and defer to other routines to realize what to do with integral types instead of iterators.

Definition at line 111 of file functions.h.

3.4.3.15 `template<typename _InputIterator> bool __gnu_debug::__valid_range_aux ( const _InputIterator & __first, const _InputIterator & __last, std::__false_type ) [inline]`

We have iterators, so figure out what kind of iterators that are to see if we can check the range ahead of time.

Definition at line 119 of file functions.h.

References `std::__iterator_category()`, and `__valid_range_aux2()`.

3.4.3.16 `template<typename _RandomAccessIterator> bool __gnu_debug::__valid_range_aux2 ( const _RandomAccessIterator & __first, const _RandomAccessIterator & __last, std::random_access_iterator_tag ) [inline]`

If the distance between two random access iterators is nonnegative, assume the range is valid.

Definition at line 90 of file functions.h.

Referenced by `__valid_range_aux()`.

3.4.3.17 `template<typename _InputIterator> bool __gnu_debug::__valid_range_aux2 ( const _InputIterator &, const _InputIterator &, std::input_iterator_tag ) [inline]`

Can't test for a valid range with input iterators, because iteration may be destructive. So we just assume that the range is valid.

<code>__rank</code>	The global rank to partition at.
<code>__begin_offsets</code>	A random-access <code>__sequence</code> <code>__begin</code> where the <code>__result</code> will be stored in. Each element of the sequence is an iterator that points to the first element on the greater part of the respective <code>__sequence</code> .

_RAIterOut __target, _DifferenceTp __length, _Compare __comp, __gnu_parallel::sequential_tag )`

Multiway Merge Frontend.

Merge the sequences specified by `seqs_begin` and `__seqs_end` into `__target`. `__seqs_begin` and `__seqs_end` must point to a sequence of pairs. These pairs must contain an iterator to the beginning of a sequence in their first entry and an iterator the `_M_end` of the same sequence in their second entry.

Ties are broken arbitrarily. See `stable_multiway_merge` for a variant that breaks ties by sequence number but is slower.

The first entries of the pairs (i.e. the begin iterators) will be moved forward.

The output sequence has to provide enough space for all elements that are written to it.

This function will merge the input sequences:

- not stable
- parallel, depending on the input size and Settings
- using sampling for splitting
- not using sentinels

Example:

```
int sequences[10][10];
for (int __i = 0; __i < 10; ++__i)
    for (int __j = 0; __j < 10; ++__j)
        sequences[__i][__j] = __j;

int __out[33];
std::vector<std::pair<int*> > seqs;
```

```

for (int __i = 0; __i < 10; ++__i)
{ seqs.push(std::make_pair<int*>(sequences[__i],
                                sequences[__i] + 10)) }

multiway_merge(seqs.begin(), seqs.end(), __target, std::less<int*>(), 33);

```

**Precondition**

All input sequences must be sorted.

Target must provide enough space to merge out length elements or the number of elements in all sequences, whichever is smaller.

**Postcondition**

[\_\_target, return \_\_value) contains merged \_\_elements from the input sequences.

return \_\_value - \_\_target = min(\_\_length, number of elements in all sequences).

**Template Parameters**

<code>_RAIterPairIterator</code>	iterator over sequence of pairs of iterators
<code>_RAIterOut</code>	iterator over target sequence
<code>_DifferenceTp</code>	difference type for the sequence
<code>_Compare</code>	strict weak ordering type to compare elements in sequences

**Parameters**

<code>__seqs_begin</code>	__begin of sequence __sequence
<code>__seqs_end</code>	__M_end of sequence __sequence
<code>__target</code>	target sequence to merge to.
<code>__comp</code>	strict weak ordering to use for element comparison.
<code>__length</code>	Maximum length to merge, possibly larger than the number of elements available.

Highly efficient 3-way merging procedure.

Merging is done with the algorithm implementation described by Peter Sanders. Basically, the idea is to minimize the number of necessary comparison after merging an element. The implementation trick that makes this fast is that the order of the sequences is stored in the instruction pointer (translated into labels in C++).

This works well for merging up to 4 sequences.

Note that making the merging stable does *not* come at a performance hit.

Whether the merging is done guarded or unguarded is selected by the used iterator class.

## Parameters

<code>__seqs_begin</code>	Begin iterator of iterator pair input sequence.
<code>__seqs_end</code>	End iterator of iterator pair input sequence.
<code>__target</code>	Begin iterator of output sequence.
<code>__comp</code>	Comparator.
<code>__length</code>	Maximum length to merge, less equal than the total number of elements available.

## Returns

Highly efficient 4-way merging procedure.

Merging is done with the algorithm implementation described by Peter Sanders. Basically, the idea is to minimize the number of necessary comparison after merging an element. ```

Multiway Merge Frontend.

Merge the sequences specified by `seqs_begin` and `__seqs_end` into `__target`. `__seqs_begin` and `__seqs_end` must point to a sequence of pairs. These pairs must contain an iterator to the beginning of a sequence in their first entry and an iterator the `_M_end` of the same sequence in their second entry.

Ties are broken arbitrarily. See `stable_multiway_merge` for a variant that breaks ties by sequence number but is slower.

The first entries of the pairs (i.e. the begin iterators) will be moved forward accordingly.

The output sequence has to provide enough space for all elements that are written to it.

This function will merge the input sequences:

- not stable
- parallel, depending on the input size and Settings
- using sampling for splitting
- using sentinels

You have to take care that the element the `_M_end` iterator points to is readable and contains a value that is greater than any other non-sentinel value in all sequences.

Example:

```
int sequences[10][11];
for (int __i = 0; __i < 10; ++__i)
    for (int __j = 0; __j < 11; ++__j)
        sequences[__i][__j] = __j; // __last one is sentinel!

int __out[33];
std::vector<std::pair<int*> > seqs;
for (int __i = 0; __i < 10; ++__i)
    { seqs.push(std::make_pair<int*>(sequences[__i],
                                    sequences[__i] + 10)) }

multiway_merge(seqs.begin(), seqs.end(), __target, std::less<int*>(), 33);
```

#### Precondition

All input sequences must be sorted.

Target must provide enough space to merge out length elements or the number of elements in all sequences, whichever is smaller.

For each `__i`, `__seqs_begin[__i].second` must be the end marker of the sequence, but also reference the one more `__sentinel` element.

#### Postcondition

`[__target, return __value)` contains merged `__elements` from the input sequences.

`return __value - __target = min(__length, number of elements in all sequences).`

### 3.8.1 Detailed Description

GNU profile code for public use.

### 3.8.2 Typedef Documentation

#### 3.8.2.1 `typedef std::unordered_map<std::string, std::string> __gnu_profile::__env_t`

Internal environment. Values can be set one of two ways: 1. In config file "var = value". The default config file path is `libstdc++-profile.conf`. 2. By setting process environment variables. For instance, in a Bash shell you can set the unit cost of iterating through a map like this: `export __map_iterate_cost_factor=5.0`. If a value is set both in the input file and through an environment variable, the environment value takes precedence.

Definition at line 65 of file `profiler_trace.h`.

### 3.8.3 Function Documentation

#### 3.8.3.1 `bool __gnu_profile::__profcxx_init( ) [inline]`

This function must be called by each instrumentation point.

The common path is inlined fully.

Definition at line 649 of file `profiler_trace.h`.

### 3.8.3.2 void \_\_gnu\_profile::\_\_report ( void ) [inline]

Final report method, registered with **atexit**.

This can also be called directly by user code, including signal handlers. It is protected against deadlocks by the reentrance guard in profiler.h. However, when called from a signal handler that triggers while within \_\_gnu\_profile (under the guarded zone), no output will be produced.

Definition at line 440 of file profiler\_trace.h.

References std::min().

### 3.8.3.3 \_\_gnu\_profile::\_GLIBCXX\_PROFILE\_DEFINE\_UNINIT\_DATA ( \_\_gnu\_cxx::\_\_mutex , \_\_global\_lock )

Master lock.

## 3.9 \_\_gnu\_sequential Namespace Reference

### 3.9.1 Detailed Description

GNU sequential classes for public use.

## 3.10 abi Namespace Reference

### 3.10.1 Detailed Description

The cross-vendor C++ Application Binary Interface. A namespace alias to \_\_cxxabiv1, but user programs should use the alias 'abi'.

A brief overview of an ABI is given in the libstdc++ FAQ, question 5.8 (you may have a copy of the FAQ locally, or you can view the online version at [http://gcc.gnu.org/onlinedocs/libstdc++/faq.html#5\\_8](http://gcc.gnu.org/onlinedocs/libstdc++/faq.html#5_8)).

GCC subscribes to a cross-vendor ABI for C++, sometimes called the IA64 ABI because it happens to be the native ABI for that platform. It is summarized at <http://www.codesourcery.com/cxx-abi/> along with the current specification.

For users of GCC greater than or equal to 3.x, entry points are available in <cxxabi.h>, which notes, *'It is not normally necessary for user programs to include this header, or use the entry points directly. However, this header is available should that be needed.'*

3.11.4.69  template<typename _InputIterator, typename _Distance> void std::advance ( _InputIterator & __i, _Distance __n )  
           [inline]
```

A generalization of pointer arithmetic.

## Parameters

<code>__i</code>	An input iterator.
<code>__n</code>	The <i>delta</i> by which to change <code>__i</code> .

## Returns

Nothing.

This increments `i` by `n`. For bidirectional and random access iterators, `__n` may be negative, in which case `__i` is decremented.

For random access iterators, this uses their `+` and `-` operations and are constant time. For other iterator classes they are linear time.

**3.11.4.82** `template<typename _Tp > pair<_Tp*, ptrdiff_t> std::get_temporary_buffer ( ptrdiff_t __len )` `[noexcept]`

Allocates a temporary buffer.

## Parameters

<code>__len</code>	The number of objects of type <code>Tp</code> .
--------------------	---

## Returns

See full description.

Reinventing the wheel, but this time with prettier spokes!

This function tries to obtain storage for `__len` adjacent `Tp` objects. The objects themselves are not constructed, of course. A `pair<>` is returned containing *the buffer's address and capacity (in the units of `sizeof(_Tp)`)*, or a pair of 0 values if no storage can be obtained. Note that the capacity obtained may be less than that requested if the memory is unavailable; you should compare `len` with the `.second` return value.

Provides the nothrow exception guarantee.

__gnu_cxx::__versa_string<_CharT, _Traits, _Alloc, _Base> & __str, _CharT __delim )`

Read a line from stream into a string.

## Parameters

<code>__is</code>	Input stream.
<code>__str</code>	Buffer to store into.
<code>__delim</code>	Character marking end of line.

## Returns

Reference to the input stream.

Stores characters from `__is` into `__str` until `__delim` is found, the end of the stream is encountered, or `str.max_size()` is reached. If `is.width()` is non-zero, that is the limit on the number of characters stored into `__str`. Any previous contents of `__str` are erased. If `delim` was encountered, it is extracted but not stored into `__str`.

```

Read a line from stream into a string.

## Parameters

<code>__is</code>	Input stream.

## Returns

## Parameters

## Returns

Read stream into a string.

**Parameters**

<code>__is</code>	Input stream.
<code>__str</code>	Buffer to store into.

**Returns**

Reference to the input stream.

Stores characters from `__is` into `__str` until whitespace is found, the end of the stream is encountered, or `str.max_size()` is reached. If `is.width()` is non-zero, that is the limit on the number of characters stored into `__str`. Any previous contents of `__str` are erased.

Read stream into a string.

**Parameters**

<code>__is</code>	Input stream.
<code>__str</code>	Buffer to store into.

**Returns**

Reference to the input stream.

Stores characters from `__is` into `__str` until whitespace is found, the end of the stream is encountered, or `str.max_size()` is reached. If `is.width()` is non-zero, that is the limit on the number of characters stored into `__str`. Any previous contents of `__str` are erased.

**3.11.4.202** `template<typename _InputIterator, typename _OutputIterator > _OutputIterator std::partial_sum ( _InputIterator __first, _InputIterator __last, _OutputIterator __result )`

Return list of partial sums.

Accumulates the values in the range `[first,last)` using the `+` operator. As each successive input value is added into the total, that partial sum is written to `__result`. Therefore, the first value in `__result` is the first value of the input, the second value in `__result` is the sum of the first and second input values, and so on.

**Parameters**

<code>__first</code>	Start of input range.
<code>__last</code>	End of input range.
<code>__result</code>	Output sum.

**Returns**

Iterator pointing just beyond the values written to `__result`.

Return list of partial sums.

Accumulates the values in the range `[first,last)` using `__binary_op`. As each successive input value is added into the total, that partial sum is written to `__result`. Therefore, the first value in `__result` is the first value of the input, the second value in `__result` is the sum of the first and second input values, and so on.

#### Parameters

<code>__first</code>	Start of input range.
<code>__last</code>	End of input range.

#### Returns

Copy a sequence, replacing each element of one value with another value.

#### Parameters

<code>__first</code>	An input iterator.
<code>__last</code>	An input iterator.
<code>__result</code>	An output iterator.
<code>__old_value</code>	The value to be replaced.
<code>__new_value</code>	The replacement value.

#### Returns

The end of the output sequence, `result+(last-first)`.

Copies each element in the input range `[__first,__last)` to the output range `[__result,__result+(__last-__first))` replacing elements equal to `__old_value` with `__new_value`.

### 3.12.1 Detailed Description

GNU debug code, replaces standard behavior with debug behavior.

Macros and namespaces used by the implementation outside of debug wrappers to verify certain properties. The `__glibcxx_requires_xxx` macros are merely wrappers around the `__glibcxx_check_xxx` wrappers when we are compiling with debug mode, but disappear when we are in release mode so that there is no checking performed in, e.g., the standard library algorithms.

#### 4.4.1 Detailed Description

```
template<typename _Tp>class __gnu_cxx::__detail::__mini_vector<_Tp >
```

`__mini_vector<>` is a stripped down version of the full-fledged `std::vector<>`.

It is to be used only for built-in types or PODs. Notable differences are:

1. Not all accessor functions are present. 2. Used ONLY for PODs. 3. No Allocator template argument. Uses operator new() to get memory, and operator delete() to free it. Caveat: The dtor does NOT free the memory allocated, so this a memory-leaking vector!

#### 4.7.1 Detailed Description

```
template<typename _Tp, typename _Poolp = __common_pool_policy<__pool, true>>class __gnu_cxx::__mt_alloc<_Tp, _Poolp>

This is a fixed size (power of 2) allocator which - when compiled with thread support - will maintain one freelist per size per thread plus a *global* one. Steps are taken to limit the per thread freelist sizes (by returning excess back to the *global* list).

#### 4.14.1 Detailed Description

Base class for `__pool_alloc`.

Uses various allocators to fulfill underlying requests (and makes as few requests as possible when in default high-speed pool mode).

Important implementation properties: 0. If globally mandated, then allocate objects from new 1. If the clients request an object of size  $> \_S\_max\_bytes$ , the resulting object will be obtained directly from new 2. In all other cases, we allocate an object of size exactly `\_S_round_up(requested_size)`. Thus the client has enough size information that we can return the object to the proper free list without permanently losing part of the object.

### 4.16.1 Detailed Description

```
template<typename _CharT, typename _Traits, typename _Alloc> class __gnu_cxx::__rc_string_base< _CharT, _Traits, _Alloc >
```

Documentation? What's that? Nathan Myers [ncm@cantrip.org](mailto:ncm@cantrip.org).

A string looks like this:

```

                                     [_Rep]
                                     _M_length
[ __rc_string_base<char_type>]      _M_capacity
_M_dataplus                        _M_refcount
_M_p ----->                      unnamed array of char_type
```

Where the `_M_p` points to the first character in the string, and you cast it to a pointer-to-`_Rep` and subtract 1 to get a pointer to the header.

This approach has the enormous advantage that a string object requires only one allocation. All the ugliness is confined within a single pair of inline functions, which each compile to a single *add* instruction: `_Rep::_M_refdata()`, and `__rc_string_base::_M_rep()`; and the allocation function which gets a block of raw bytes and with room enough and constructs a `_Rep` object at the front.

The reason you want `_M_data` pointing to the character array and not the `_Rep` is so that the debugger can see the string contents. (Probably we should add a non-inline member to get the `_Rep` for the debugger to use, so users can check the actual string length.)

Note that the `_Rep` object is a POD so that you can have a static *empty string* `_Rep` object already *constructed* before static constructors have run. The reference-count encoding is chosen so that a 0 indicates one reference, so you never try to destroy the empty-string `_Rep` object.

All but the last paragraph is considered pretty conventional for a C++ string implementation.

0 if their values are equivalent, or  $> 0$  if this substring is ordered after the substring of `__str`. Determines the effective length `rlen` of the strings to compare as the smallest of the lengths of the substrings. The function then compares the two strings by calling `traits::compare(substring.data(), str.substr(pos2, n2).data(), rlen)`. If the result of the comparison is nonzero returns it, otherwise the shorter one is ordered first.

Returns an integer  $< 0$  if the substring is ordered before `__s`,  $0$  if their values are equivalent, or  $> 0$  if the substring is ordered after `__s`. Determines the effective length `rlen` of the strings to compare as the smallest of the length of the substring and the length of a string constructed from `__s`. Set value to string of length 1.

## Parameters

<code>__c</code>	Source character.
------------------	-------------------

Assigning to a character makes this string length 1 and `(*this)[0] == __c`.

Subscript access to the data contained in the string.

## Parameters

<code>__pos</code>	The index of the character to access.
--------------------	---------------------------------------

## Returns

Read-only (constant) reference to the character.

This operator allows for easy, array-style, data access. Note that data access with this operator is unchecked and `out_of_range` lookups are not defined. (For checked lookups see `at()`.)

------------------------	--------------------------------

## Exceptions

<i>std::length_error</i>	If <code>__res_arg</code> exceeds <code>max_size()</code> .

The advantage of this function is that if optimal code is a necessity and the user can determine the string length that will be required, the user can reserve the memory in advance, and thus prevent a possible reallocation of memory and copying of string data.

## 4.19.1 Detailed Description

`template<typename _ToType> struct __gnu_cxx::Caster<_ToType>`

These functions are here to allow containers to support non standard pointer types. For normal pointers, these resolve to the use of the standard cast operation. For other types the functions will perform the appropriate cast to/from the custom pointer class so long as that class meets the following conditions: 1) has a typedef `element_type` which names the type it points to. 2) has a `get()` const method which returns `element_type*`. 3) has a constructor which can take one `element_type*` argument. This type supports the semantics of the pointer cast operators (below.)

Mapping from character type to associated types.

### Note

This is an implementation class for the generic version of `char_traits`. It defines `int_type`, `off_type`, `pos_type`, and `state_type`. By default these are unsigned long, streamoff, streampos, and mbstate\_t. Users who need a different set of types, but who don't need to change the definitions of any function defined in `char_traits`, can specialize `__gnu_cxx::Char_types` while leaving `__gnu_cxx::char_traits` alone.

#### 4.23.1 Detailed Description

```
template<typename _Storage_policy> class __gnu_cxx::Pointer_adapter<_Storage_policy>
```

The following provides an 'alternative pointer' that works with the containers when specified as the pointer typedef of the allocator.

The pointer type used with the containers doesn't have to be this class, but it must support the implicit conversions, pointer arithmetic, comparison operators, etc. that are supported by this class, and avoid raising compile-time ambiguities. Because creating a working pointer can be challenging, this pointer template was designed to wrapper an easier storage policy type, so that it becomes reusable for creating other pointer types.

A key point of this class is also that it allows container writers to 'assume' `Allocator::pointer` is a typedef for a normal pointer. This class supports most of the conventions of a true pointer, and can, for instance handle implicit conversion to const and base class pointer types. The only impositions on container writers to support extended pointers are: 1) use the `Allocator::pointer` typedef appropriately for pointer types. 2) if you need pointer casting, use the `__pointer_cast<>` functions from `ext/cast.h`. This allows pointer cast operations to be overloaded as necessary by custom pointers.

Note: The const qualifier works with this pointer adapter as follows:

```
_Tp* == _Pointer_adapter<_Std_pointer_impl<_Tp>>; const _Tp* == _Pointer_adapter<_Std_pointer_impl<const
_Tp>>; _Tp* const == const _Pointer_adapter<_Std_pointer_impl<_Tp>>; const _Tp* const == const _Pointer_
adapter<_Std_pointer_impl<const _Tp>>;

#### 4.24.1 Detailed Description

```
template<typename _Tp>class __gnu_cxx::_Relative_pointer_impl< _Tp >
```

A storage policy for use with `_Pointer_adapter<>` which stores the pointer's address as an offset value which is relative to its own address.

This is intended for pointers within shared memory regions which might be mapped at different addresses by different processes. For null pointers, a value of 1 is used. (0 is legitimate sometimes for nodes in circularly linked lists) This value was chosen as the least likely to generate an incorrect null, As there is no reason why any normal pointer would point 1 byte into its own pointer address.

```
template<typename _Tp>class __gnu_cxx::Std_pointer_impl<_Tp>

A storage policy for use with `_Pointer_adapter<>` which yields a standard pointer.

Complexity: Worst case complexity is O(N), but that is hardly ever hit. If and when this particular case is encountered, the next few cases are guaranteed to have a worst case complexity of O(1)! #### 4.32.1 Detailed Description

```
template<typename _CharT>struct __gnu_cxx::char_traits< _CharT >
```

Base class used to implement `std::char_traits`.

##### Note

For any given actual character type, this definition is probably wrong. (Most of the member functions are likely to be right, but the `int_type` and `state_type` typedefs, and the `eof()` member function, are likely to be wrong.) The reason this class exists is so users can specialize it. Classes in namespace `std` may not be specialized for fundamental types, but classes in namespace `__gnu_cxx` may be.

See <http://gcc.gnu.org/onlinedocs/libstdc++/manual/bk01pt05ch13s03.html> for advice on how to make use of this class for *unusual* character types. Also, check out `include/ext/pod_char_traits.h`.

template<typename \_CharT, typename \_Traits = std::char\_traits<\_CharT>> class `__gnu_cxx::stdio_filebuf<_CharT, _Traits>`

Provides a layer of compatibility for C/POSIX.

This GNU extension provides extensions for working with standard C FILE\*'s and POSIX file descriptors. It must be instantiated by the user with the type of character used in the file stream, e.g., `stdio_filebuf<char>`.

Definition at line 50 of file `stdio_filebuf.h`.

#### 4.52.2 Constructor & Destructor Documentation

4.52.2.1 template<typename \_CharT, typename \_Traits = std::char\_traits<\_CharT>> `__gnu_cxx::stdio_filebuf<_CharT, _Traits>::stdio_filebuf( )` [inline]

deferred initialization

Definition at line 65 of file `stdio_filebuf.h`.

4.52.2.2 template<typename \_CharT, typename \_Traits> `__gnu_cxx::stdio_filebuf<_CharT, _Traits>::stdio_filebuf( int __fd, std::ios_base::openmode __mode, size_t __size = static_cast<size_t>(BUFSIZ) )`

##### Parameters

<code>__fd</code>	An open file descriptor.
<code>__mode</code>	Same meaning as in a standard filebuf.
<code>__size</code>	Optimal or preferred size of internal buffer, in chars.

This constructor associates a file stream buffer with an open POSIX file descriptor. The file descriptor will be automatically closed when the `stdio_filebuf` is closed/destroyed.

Definition at line 128 of file `stdio_filebuf.h`.

4.52.2.3 template<typename \_CharT, typename \_Traits> `__gnu_cxx::stdio_filebuf<_CharT, _Traits>::stdio_filebuf( std::__c_file * __f, std::ios_base::openmode __mode, size_t __size = static_cast<size_t>(BUFSIZ) )`

## Parameters

<code>__f</code>	An open <code>FILE*</code> .
<code>__mode</code>	Same meaning as in a standard filebuf.
<code>__size</code>	Optimal or preferred size of internal buffer, in chars. Defaults to system's <code>BUFSIZ</code> .

This constructor associates a file stream buffer with an open C `FILE*`. The `FILE*` will not be automatically closed when the `stdio_filebuf` is closed/destroyed.

Definition at line 144 of file `stdio_filebuf.h`.

4.52.2.4 `template<typename _CharT, typename _Traits > __gnu_cxx::stdio_filebuf< _CharT, _Traits >::~~stdio_filebuf ( )`

Closes the external data stream if the file descriptor constructor was used.

Definition at line 123 of file `stdio_filebuf.h`.

Once associated with an external data stream, this function can be used to access the underlying POSIX file descriptor. Note that there is no way for the library to track what you do with the descriptor, so be careful.

Definition at line 109 of file `stdio_filebuf.h`.

#### 4.64.1 Detailed Description

```
template<typename _Iterator, typename _Sequence>class __gnu_debug::_Safe_iterator< _Iterator, _Sequence >
```

Safe iterator wrapper.

The class template `_Safe_iterator` is a wrapper around an iterator that tracks the iterator's movement among sequences and checks that operations performed on the "safe" iterator are legal. In addition to the basic iterator operations (which are validated, and then passed to the underlying iterator), `_Safe_iterator` has member functions for iterator invalidation, attaching/detaching the iterator from sequences, and querying the iterator's state.

#### 4.65.1 Detailed Description

Basic functionality for a *safe* iterator.

The `_Safe_iterator_base` base class implements the functionality of a safe iterator that is not specific to a particular iterator type. It contains a pointer back to the sequence it references along with iterator version information and pointers to form a doubly-linked list of iterators referenced by the container.

This class must not perform any operations that can throw an exception, or the exception guarantees of derived iterators will be broken.

#### 4.66.1 Detailed Description

```
template<typename _Iterator, typename _Sequence>class __gnu_debug::_Safe_local_iterator< _Iterator, _Sequence >
```

Safe iterator wrapper.

The class template `_Safe_local_iterator` is a wrapper around an iterator that tracks the iterator's movement among sequences and checks that operations performed on the "safe" iterator are legal. In addition to the basic iterator operations (which are validated, and then passed to the underlying iterator), `_Safe_local_iterator` has member functions for iterator invalidation, attaching/detaching the iterator from sequences, and querying the iterator's state.

## 4.67.1 Detailed Description

Basic functionality for a *safe* iterator.

The `_Safe_local_iterator_base` base class implements the functionality of a safe local iterator that is not specific to a particular iterator type. It contains a pointer back to the container it references along with iterator version information and pointers to form a doubly-linked list of local iterators referenced by the container.

This class must not perform any operations that can throw an exception, or the exception guarantees of derived iterators will be broken.

##### 4.68.1 Detailed Description

```
template<typename _Sequence> class __gnu_debug::Safe_sequence<_Sequence>
```

Base class for constructing a *safe* sequence type that tracks iterators that reference it.

The class template `_Safe_sequence` simplifies the construction of *safe* sequences that track the iterators that reference the sequence, so that the iterators are notified of changes in the sequence that may affect their operation, e.g., if the container invalidates its iterators or is destructed. This class template may only be used by deriving from it and passing the name of the derived class as its template parameter via the curiously recurring template pattern. The derived class must have `iterator` and `const_iterator` types that are instantiations of class template `_Safe_iterator` for this sequence. Iterators will then be tracked automatically.

#### 4.69.1 Detailed Description

Base class that supports tracking of iterators that reference a sequence.

The `_Safe_sequence_base` class provides basic support for tracking iterators into a sequence. Sequences that track iterators must derived from `_Safe_sequence_base` publicly, so that safe iterators (which inherit `_Safe_iterator_base`) can attach to them. This class contains two linked lists of iterators, one for constant iterators and one for mutable iterators, and a version number that allows very fast invalidation of all iterators that reference the container.

This class must ensure that no operation on it may throw an exception, otherwise *safe* sequences may fail to provide the exception-safety guarantees required by the C++ standard.

#### 4.71.1 Detailed Description

Base class that supports tracking of local iterators that reference an unordered container.

The `_Safe_unordered_container_base` class provides basic support for tracking iterators into an unordered container. Containers that track iterators must derived from `_Safe_unordered_container_base` publicly, so that safe iterators (which inherit `_Safe_iterator_base`) can attach to them. This class contains four linked lists of iterators, one for constant iterators, one for mutable iterators, one for constant local iterators, one for mutable local iterators and a version number that allows very fast invalidation of all iterators that reference the container.

This class must ensure that no operation on it may throw an exception, otherwise *safe* containers may fail to provide the exception-safety guarantees required by the C++ standard.

## 4.117.1 Detailed Description

```
template<typename _Tp, typename _Compare>class __gnu_parallel::_LoserTreeBase<_Tp, _Compare>
```

Guarded loser/tournament tree.

The smallest element is at the top.

Guarding is done explicitly through one flag `_M_sup` per element, `inf` is not needed due to a better initialization routine. This is a well-performing variant.

## Parameters

<code>_Tp</code>	the element type
<code>_Compare</code>	the comparator to use, defaults to <code>std::less&lt;_Tp&gt;</code>

Definition at line 55 of file `losertree.h`.

### Static Public Attributes

- static const bool `_M_use_pointer`

#### 4.126.1 Detailed Description

```
template<typename _Tp> struct __gnu_parallel::_LoserTreeTraits<_Tp>
```

Traits for determining whether the loser tree should use pointers or copies.

The field "`_M_use_pointer`" is used to determine whether to use pointers in the loser trees or whether to copy the values into the loser tree.

The default behavior is to use pointers if the data type is 4 times as big as the pointer to it.

Specialize for your data type to customize the behavior.

Example:

```
template<> struct _LoserTreeTraits<int> { static const bool _M_use_pointer = false; };
template<> struct _LoserTreeTraits<heavyweight_type> { static const bool _M_use_pointer = true; };
```

<i>_Alloc</i>	Allocator type.
<i>Store_Hash</i>	If key type stores extra metadata. Defaults to false.
<i>Comb_Hash_Fn</i>	Combining hash functor. If <i>Hash_Fn</i> is not null_type, then this is the ranged-hash functor; otherwise, this is the range-hashing functor. XXX(See Design::Hash-Based Containers::Hash Policies.) Default <code>direct_mask_range_hashing</code> .
<i>Resize_Policy</i>	Resizes hash. Defaults to <code>hash_standard_resize_policy</code> , using <code>hash_exponential_size_policy</code> and <code>hash_load_check_resize_trigger</code> .

Bases are: `detail::hash_eq_fn`, `Resize_Policy`, `detail::ranged_hash_fn`, `detail::types_traits`. (Optional: `detail::debug_map_base`.)

`template<typename Key, typename Mapped, typename Hash_Fn, typename Eq_Fn, typename _Alloc, bool Store_Hash, typename Comb_Probe_Fn, typename Probe_Fn, typename Resize_Policy>class __gnu_pbds::detail::gp_ht_map< Key, Mapped, Hash_Fn, Eq_Fn, _Alloc, Store_Hash, Comb_Probe_Fn, Probe_Fn, Resize_Policy >`

A general-probing hash-based container.

#### Template Parameters

<i>Key</i>	Key type.
<i>Mapped</i>	Map type.
<i>Hash_Fn</i>	Hashing functor. Default is <code>__gnu_cxx::hash</code> .
<i>Eq_Fn</i>	Equal functor. Default <code>std::equal_to&lt;Key&gt;</code>
<i>_Alloc</i>	Allocator type.
<i>Store_Hash</i>	If key type stores extra metadata. Defaults to false.
<i>Comb_Probe_Fn</i>	Combining probe functor. If <i>Hash_Fn</i> is not null_type, then this is the ranged-probe functor; otherwise, this is the range-hashing functor. XXX See Design::Hash-Based Containers::Hash Policies. Default <code>direct_mask_range_hashing</code> .
<i>Probe_Fn</i>	Probe functor. Defaults to <code>linear_probe_fn</code> , also <code>quadratic_probe_fn</code> .
<i>Resize_Policy</i>	Resizes hash. Defaults to <code>hash_standard_resize_policy</code> , using <code>hash_exponential_size_policy</code> and <code>hash_load_check_resize_trigger</code> .

Bases are: `detail::hash_eq_fn`, `Resize_Policy`, `detail::ranged_probe_fn`, `detail::types_traits`. (Optional: `detail::debug_map_base`.)

#### 4.330.1 Detailed Description

```
template<typename Key, typename Mapped, typename Hash_Fn = typename detail::default_hash_fn<Key>::type, typename Eq_Fn
= typename detail::default_eq_fn<Key>::type, typename Comb_Probe_Fn = detail::default_comb_hash_fn::type, typename Probe_Fn

pbds::gp_hash_table< Key, Mapped, Hash_Fn, Eq_Fn, Comb_Probe_Fn, Probe_Fn, Resize_Policy, Store_Hash, _Alloc >
```

A general-probing hash-based associative container.

##### Template Parameters

<i>Key</i>	Key type.
<i>Mapped</i>	Map type.
<i>Hash_Fn</i>	Hashing functor.
<i>Eq_Fn</i>	Equal functor.
<i>Comb_Probe_Fn</i>	Combining probe functor. If Hash_Fn is not null_type, then this is the ranged-probe functor; otherwise, this is the range-hashing functor. XXX See Design::Hash-Based Containers::Hash Policies.
<i>Probe_Fn</i>	Probe functor.
<i>Resize_Policy</i>	Resizes hash.
<i>Store_Hash</i>	Indicates whether the hash value will be stored along with each key. If Hash_Fn is null_type, then the container will not compile if this value is true
<i>_Alloc</i>	Allocator type.

Base tag choices are: `gp_hash_tag`.

Base is `basic_hash_table`.
